fractional distillation of such gaseous mixture in the manner hereinbefore described, the combination with a liquefier comprising a series of closed evaporator trays, troughs or sections, connected to permit passage of liquid through the series and provided with conduits, in contact with liquid in such trays, for the passage of gas to be liquefied, and with separate gas-outlets, of a plurality of heat-exchangers surrounding the said liquefier and each having adjacent conduits for the passage of gas to be liquefied and for the gas escaping from the said evaporator-trays, the said conduits of the several exchangers being connected to the corresponding conduits and outlets of different evaporator-trays of the series; a source of supply of compressed gas to be liquefied, to which the corresponding conduits of the exchangers are connected in multiple, means for collecting the gas escaping from the several exchangers, and means for collecting the liquefied mixture from the conduits of the several trays.

5. In an apparatus for the separation of a gaseous mixture into its constituents by the liquefaction and subsequent evaporation or fractional distillation of such gaseous mixture in the manner hereinbefore described, the combination with a liquefier comprising a series of closed evaporator trays, troughs or sections connected to permit passage of liquid through the series, and provided with conduits, in contact with liquid in such trays, for the passage of the gas to be liquefied, and the separate gas-outlets, of a plurality of heat-exchangers each having adjacent conduits for the passage of gas to be liquefied and for the gas escaping from the evaporator-trays, such conduits of the several exchangers being connected respectively to the corresponding conduits and outlets of different trays of the series; a source of supply of compressed gas to be liquefied, to which the corresponding conduits of the exchangers are connected in multiple, and a collector into which the gas from the several exchangers is discharged, provided with means for separating gases discharged from the different exchangers of the series.

6. In an apparatus for the separation of a gaseous mixture into its constituents by the liquefaction and subsequent evaporation or fractional distillation of such gaseous mixture in the manner hereinbefore described, the combination with a liquefier comprising a series of closed evaporator trays, troughs, or sections connected to permit passage of liquid through the series, and provided with conduits, in contact with liquid in such trays, for the passage of the gas to be liquefied, and with separate gas-outlets, of a plurality of heat-exchangers each having adjacent conduits for the passage of gas to be liquefied and for the gas escaping from the evaporator-trays, such conduits of the several exchangers being connected respectively to the corresponding conduits and outlets of different trays of the series; a source of supply of compressed gas to be liquefied, to which the corresponding conduits of the exchangers are connected in multiple, a collector into which the gas from the several exchangers is discharged, and valves in said collector adapted to permit separation of gas flowing from different exchangers of the series.

7. In an apparatus for the separation of a gaseous mixture into its constituents by the liquefaction and subsequent evaporation or fractional distillation of such gaseous mixture in the manner hereinbefore described, the combination with a liquefier comprising a series of closed evaporator trays, troughs or sections, connected to permit passage of liquid through the series, and provided with conduits, in contact with liquid in such trays, for the passage of the gas to be liquefied, and with separate gas-outlets, of a plurality of heat-exchangers each having adjacent conduits for the passage of gas to be liquefied and for the gas escaping from the evaporator-trays, such conduits of the several exchangers being connected respectively to the corresponding conduits and outlets of different trays of the series; a source of supply of compressed gas to be liquefied, to which the corresponding conduits of the exchangers are connected in multiple, and means for collecting the liquefied mixture from the conduits of the several trays, and for conducting said mixture to the uppermost of said trays.

8. In an apparatus for the separation of a gaseous mixture into its constituents by the liquefaction and subsequent evaporation or fractional distillation of such gaseous mixture in the manner hereinbefore described, the combination with a liquefier comprising a series of closed evaporator trays, troughs or sections connected to permit passage of liquid through the series, but sealed against the passage of gas from one to the other, and provided with conduits, in contact with liquid in such trays, for the passage of the gas to be liquefied, and with separate gas-outlets, of a plurality of heat-exchangers, each having adjacent conduits for the passage of gas to be liquefied and for the gas escaping from the evaporator-trays, such conduits of the several exchangers being connected respectively to the corresponding conduits and outlets of different trays of the series; a source of supply of compressed gas to be liquefied, to which the corresponding conduits of the exchangers are connected in multiple, and means for collecting the liquefied mixture from the conduits of the several trays, and for conducting said mixture to the uppermost of said trays.

9. In an apparatus for the separation of a gaseous mixture into its constituents by the liquefaction and subsequent evaporation or fractional distillation of such gaseous mixture in the manner hereinbefore described, the combination, with a liquefier comprising a series of closed evaporator trays, troughs or sections, connected to permit passage of liquid through the series, and provided with conduits, in contact with liquid in such trays, for the passage of the gas to be liquefied, and with separate gas-outlets, of a plurality of heat-exchangers each having adjacent conduits for the passage of gas to be liquefied and for the gas escaping from the evaporator-trays, such conduits of the several exchangers being connected respectively to the corresponding conduits and outlets of different trays of the series; a source of supply of compressed gas to be liquefied, to which the corresponding conduits of the exchangers are connected in multiple, means for collecting the liquefied mixture from the conduits of the several trays, and for conducting said mixture to the uppermost of said trays, and means for collecting the gases escaping from the several exchangers.

10. In an apparatus for the separation of a gaseous mixture into its constituents by the liquefaction and subsequent evaporation or fractional distillation of such gaseous mixture in the manner hereinbefore described, the combination with a liquefier comprising a series of closed evaporator trays, troughs or sections, connected to permit passage of liquid through the series and provided with conduits, in contact with liquid in such trays, for the passage of gas to be liquefied, and with separate gas-outlets, of a plurality of heat-exchangers surrounding the said liquefier and each having adjacent conduits for the passage of gas to be liquefied and for the gas escaping from the said evaporator-trays, the said conduits of the several exchangers being connected respectively to the corresponding conduits and outlets of different evaporator-trays of the series; a source of supply of compressed gas to be liquefied, to which the corresponding conduits of the exchangers are connected in multiple, means for collecting the gas escaping from the several exchangers, and means for collecting the liquefied mixture from the conduits of the several trays, and for conducting said mixture to the uppermost of said trays.

11. In an apparatus for the separation of a gaseous mixture into its constituents by the liquefaction and subsequent evaporation or fractional distillation of such gaseous mixture in the manner hereinbefore described, the combination with a liquefier comprising a series of closed evaporator trays, troughs or sections connected to permit passage of liquid through the series, but sealed against the passage of gas from one to the other, and provided with conduits, in contact with liquid in such trays, for the passage of the gas to be liquefied, and with separate gas-outlets, of a plurality of heat-exchangers each having adjacent conduits for the passage of gas to be liquefied and for the gas escaping from the evaporator-trays, such conduits of the several exchangers being connected respectively to the corresponding conduits and outlets of different trays of the series; a source of supply of compressed gas to be liquefied, to which the corresponding conduits of the exchangers are connected in multiple, a collector into which the gas from the several exchangers is discharged, provided with means for separating gases discharged from the different exchangers of the series, and means for collecting the liquefied mixture from the conduits of the several trays and for conveying said mixture to the uppermost of said trays.

12. In an apparatus for the separation of a gaseous mixture into its constituents by the liquefaction and subsequent evaporation or fractional distillation of such gaseous mixture in the manner hereinbefore described, the combination with a liquefier comprising a series of closed evaporator trays, troughs or sections connected to permit passage of liquid through the series, and provided with conduits, in contact with liquid in such trays, for the passage of the gas to be liquefied, and with separate gas-outlets, of a plurality of heat-exchangers each having adjacent conduits for the passage of gas to be liquefied and for the gas escaping from the evaporator-trays, such conduits of the several exchangers being connected respectively to the corresponding conduits and outlets of different trays of the series; a source of supply of compressed gas to be liquefied, to which the corresponding conduits of the exchangers are connected in multiple, a collector into which the gas from the several exchangers is discharged, valves in said collector adapted to permit separation of gas flowing from different exchangers of the series, and means for collecting the liquefied mixture from the conduits of the several trays and for conveying said mixture to the uppermost of said trays.

13. In an apparatus for the separation of a gaseous mixture into its constituents by the liquefaction and subsequent evaporation or fractional distillation of such gaseous mixture in the manner hereinbefore described, the combination with a liquefier comprising a series of closed evaporator trays, troughs or sections, connected to permit passage of liquid through the series, and provided with conduits, in contact with liquid in such trays, for the passage of the gas to be liquefied, and with separate gas-outlets, of a plurality of heat-exchangers each having adjacent conduits for the passage of gas to be liquefied and for the gas escaping from the evaporator-trays, such conduits of the several exchangers being connected respectively to the corresponding conduits and outlets of different trays of the series; a source of supply of compressed gas to be liquefied, to which the corresponding conduits of the exchangers are connected in multiple, and means for collecting the liquefied mixture from the conduits of the several trays, for filtering said mixture and for delivering the filtered liquid to the uppermost of said trays.

14. In an apparatus for the separation of a gaseous mixture into its constituents by the liquefaction and subsequent evaporation or fractional distillation of such gaseous mixture in the manner hereinbefore described, the combination with a liquefier comprising a series of closed evaporator trays, troughs or sections connected to permit passage of liquid through the series, but sealed against the passage of gas from one to the other, and provided with conduits, in contact with liquid in such trays, for the passage of the gas to be liquefied, and with separate gas-outlets, of a plurality of heat-exchangers, each having adjacent conduits for the passage of gas to be liquefied and for the gas escaping from the evaporator-trays, such conduits of the several exchangers being connected respectively to the corresponding conduits and outlets of different trays of the series; a source of supply of compressed gas to be liquefied, to which the corresponding conduits of the exchangers are connected in multiple, and means for collecting the liquefied mixture from the conduits of the several trays, for filtering said mixture and for delivering the filtered liquid to the uppermost of said trays.

15. In an apparatus for the separation of a gaseous mixture into its constituents by the liquefaction and subsequent evaporation or fractional distillation of such gaseous mixture in the manner hereinbefore described, the combination, with a liquefier comprising a series of closed evaporator trays, troughs or sections, connected to permit passage of liquid through the series, and provided with conduits, in contact with liquid in such trays, for the passage of the gas to be liquefied, and with separate gas-outlets, of a plurality of heat-exchangers, each having adjacent conduits for the passage of gas to be liquefied and for the gas escaping from the evaporator-trays, such conduits of the several exchangers being connected respectively to the corresponding conduits and outlets of different trays of the series; a source of supply of compressed gas to be liquefied, to which the corresponding conduits of the exchangers are connected in multiple, means for collecting the liquefied mixture from the conduits of the several trays, for filtering the same, and for delivering the filtered liquid to the uppermost of said trays, and means for collecting the gases escaping from the several exchangers

16. In an apparatus for the separation of a gaseous mixture into its constituents by the liquefaction and subsequent evaporation or fractional distillation of such gaseous mixture in the manner hereinbefore described, the combination with a liquefier comprising a series of closed evaporator trays, troughs or sections, connected to permit passage of liquid through the series and provided with conduits, in contact with liquid in such trays, for the passage of gas to be liquefied, and with separate gas-outlets, of a plurality of heat-exchangers surrounding the said liquefier and each having adjacent conduits for the passage of gas to be liquefied and for the gas escaping from the said evaporator-trays, the said conduits of the several exchangers being connected to the corresponding conduits and outlets of different evaporator-trays of the series; a source of supply of compressed gas to be liquefied, to which the corresponding conduits of the exchangers are connected in multiple, means for collecting the gas escaping from the several exchangers, and means for collecting the liquefied mixture from the conduits of the several trays for filtering the same and for delivering the filtered liquid to the uppermost of said trays.

17. In an apparatus for the separation of a gaseous mixture into its constituents by the liquefaction and subsequent evaporation or fractional distillation of such gaseous mixture in the manner hereinbefore described, the combination with a liquefier comprising a series of closed evaporator trays, troughs or sections connected to permit passage of liquid through the series, and provided with conduits, in contact with liquid in such trays, for the passage of the gas to be liquefied, and with separate gas-outlets, of a plurality of heat-exchangers each having adjacent conduits for the passage of gas to be liquefied and for the gas escaping from the evaporator-trays, such conduits of the several exchangers being connected respectively to the corresponding conduits and outlets of different trays of the series; a source of supply of compressed gas to be liquefied, to which the corresponding conduits of the exchanger are connected in multiple, a collector into which the gas from the several exchangers is discharged, provided with means for separating gases discharged from the different exchangers of the series, and means for collecting the said liquid from the conduits of said trays, for filtering the same and for delivering the filtered liquid to the uppermost of said trays.

18. In an apparatus for the separation of a gaseous mixture into its constituents by the liquefaction and subsequent evaporation or fractional distillation of such gaseous mixture in the manner hereinbefore described, the combination with a liquefier comprising a series of closed evaporator trays, troughs or sections connected to permit passage of liquid through the series, and provided with conduits, in contact with liquid in such trays, for the passage of the gas to be liquefied, and with separate gas-outlets, of a plurality of heat-exchangers each having adjacent conduits for the passage of gas to be liquefied and for the gas escaping from the evaporator-trays, such conduits of the several exchangers being connected respectively to the corresponding conduits and outlets of different trays of the series; a source of supply of compressed gas to be liquefied, to which the corresponding conduits of the exchangers are connected in multiple, a collector in which the gas from the several exchangers is discharged valves in said collector adapted to permit separation of gas flowing from different exchangers of the series, and means for collecting the said liquid from the conduits of said trays, for filtering the same and for delivering the filtered liquid to the uppermost of said trays.

19. In an apparatus for the separation of a gaseous mixture into its constituents by the liquefaction and subsequent evaporation or fractional distillation of such gaseous mixture in the manner hereinbefore described the combination with each trough or tray of the liquefier of a window to permit inspection of the interior of such trough or tray and of the flow of liquefied gaseous mixture from one trough or tray of the liquefier to the next and the intensity of the evaporation of the liquefied gaseous mixture and an outlet for cold dry gas adjacent to such window all for the purpose hereinbefore described.

20. In an apparatus for the separation of a gaseous mixture into its constituents by the liquefaction and subsequent evaporation or fractional distillation of such gaseous mixture in the manner hereinbefore described the combination with each trough or tray of the liquefier of a window and an outlet for cold dry gas adjacent to such window, a mirror and an electric lamp to act with such window to permit inspection of the interior of such trough or tray and of the flow of liquefied gaseous mixture from one trough or tray of the liquefier to the next and the intensity of the evaporation of the liquefied gaseous mixture all for the purpose hereinbefore described.

21. In an apparatus for the separation of a gaseous mixture into its constituents by liquefaction and subsequent evaporation or fractional distillation of such gaseous mixture, in the manner hereinbefore described, the combination with a liquefier comprising a plurality of evaporating-chambers arranged one above the other and connected in series and arranged to permit the flow of the liquefied gaseous mixture from one to the other but to prevent the flow of gas from one to the other, said series comprising intermediate chambers from which gaseous mixtures of different proportions may be obtained, and end chambers from which gases of relative purity may be obtained, of an exchanger comprising a plurality of sections arranged one above the other, surrounding the liquefier and each corresponding to one of the chambers of said liquefier, each exchanger-section having pipes, connected to its corresponding liquefier-chamber, through which the gaseous mixture to be cooled and eventually liquefied is made to pass, and having also channels to contain such pipes, each channel connected to the corresponding chamber of the liquefier.

22. In an apparatus for the separation of a gaseous mixture into its constituents by liquefaction and subsequent evaporation or fractional distillation of such gaseous mixture, in the manner hereinbefore described, the combination with a liquefier comprising a plurality of evaporating-chambers arranged one above the other and connected in series and arranged to permit the flow of the liquefied gaseous mixture from one to the other but to prevent the flow of gas from one to the other, said series comprising intermediate chambers from which gaseous mixtures of different proportions may be obtained, and end chambers from which gases of relative purity may be obtained, of an exchanger comprising a plurality of sections arranged one above the other, surrounding the liquefier, and each corresponding to one of the chambers of said liquefier, each exchanger-section having channels connected to the corresponding chamber of the liquefier and leading spirally outward therefrom for the escape of gas from said chamber, and having also pipes in such channels, connected to the corresponding liquefier-chamber, through which the gaseous mixture to be cooled and eventually liquefied is made to pass.

23. In an apparatus for the separation of a gaseous mixture into its constituents by the liquefaction and subsequent evaporation or fractional distillation of such gaseous mixture in the manner hereinbefore described, the combination of a plurality of sections of the apparatus adapted to resist pressure and arranged to be exposed to low temperatures in the operation of the apparatus and provided on adjacent sides with troughs adapted to contain water and with projections adapted to enter said troughs, whereby when water in such troughs is frozen the parts are secured together and means for producing within the apparatus a temperature below the freezing-point of the liquid in said troughs.

24. The combination with the troughs or trays of an exchanger for use in an apparatus for the separation of a gaseous mixture into its constituents by the liquefaction and subsequent evaporation or fractional distillation of such gaseous mixture in the manner hereinbefore described of feet upon some of such troughs or trays to enter into channels in the others of the said troughs or trays and channels upon the others of the said troughs or trays to receive the said feet and to receive water for the purpose hereinbefore described and means for producing within the apparatus a temperature lower than the freezing-point of the liquid within said channels.

25. In an apparatus for the separation of a gaseous mixture into its constituents by the liquefaction and subsequent evaporation or fractional distillation of such gaseous mixture in the manner hereinbefore described a liquefier consisting in the combination of a number of structurally-separate trays means to permit the flow of liquid from tray to tray and preserve a quantity of liquid in each tray, ice-joints between the trays, and coils immersed in the liquid in said trays and serving for the liquefaction of gaseous mixture in their interiors and for the evaporation of the liquid in the said trays for the purpose hereinbefore described.

26. An apparatus for the separation of a gaseous mixture into its constituents by the liquefaction and subsequent evaporation or fractional distillation of such gaseous mixture in the manner hereinbefore described consisting essentially in the combination of an exchanger and liquefier containing respectively corresponding numbers of sections and trays or troughs varying as to number according to the degree of purity desired in the gases to be separated and collected, the sections containing pipes for the passage of the gaseous mixture to be liquefied and channels containing the said pipes and each in communication with one of the trays or troughs and the trays or troughs each in communication with the channel in the corresponding section and a coil in each tray or trough in communication with the pipe in the corresponding channel, a liquid-collector in communication with the said coils, means to regulate the flow of liquefied gaseous mixture from each of the said coils to the said liquid-collector, a filter in communication with the said liquid-collector and with the uppermost of the said trays or troughs, a float in the lowest of the said trays or troughs, a gas-collector in communication with the said channels and provided with an outlet for gases not desired to be collected, means to regulate the escape of gases thereby, means to regulate the number of the said channels which are allowed to communicate at any time with the outlet for gases which it is not desired to collect and the number of the said channels from which gases are to be conducted to the places to which the said gas-collector may be connected all for the purposes hereinbefore described.

27. An apparatus for the separation of a gaseous mixture into its constituents by the liquefaction and subsequent evaporation or fractional distillation of such gaseous mixture in the manner hereinbefore described consisting essentially in the combination of an exchanger and liquefier containing respectively corresponding numbers of sections and trays or troughs varying as to number according to the degree of purity desired in the gases to be separated and collected, the sections containing pipes for the passage of the gaseous mixture to be liquefied and channels containing the said pipes and each in communication with one of the trays or troughs and the trays or troughs each in communication with the channel in the corresponding section and a coil in each tray or trough in communication with the pipe in the corresponding channel, a liquid-collector in communication with the said coils, means to regulate the flow of liquefied gaseous mixture from each of the said coils to the said liquid-collector, a filter in communication with the said liquid-collector and with the uppermost of the said trays or troughs, a float in the lowest of the said trays or troughs, a gas-collector in communication with the said channels and provided with an outlet for gases not desired to be collected, means to regulate the escape of gases thereby, means to regulate the number of the said channels which are allowed to communicate at any time with the outlet for gases which it is not desired to collect and the number of the said channels from which gases are to be conducted to the places to which the said gas-collector may be connected all for the purposes hereinbefore described.

28. An apparatus for the separation of a gaseous mixture into its constituents by the liquefaction and subsequent evaporation or fractional distillation of such gaseous mixture in the manner hereinbefore described consisting essentially in the combination of an exchanger and liquefier containing respectively corresponding numbers of sections and trays or troughs varying as to number according to the degree of purity desired in the gases to be separated and collected, the sections containing pipes for the passage of the gaseous mixtures to be liquefied and channels containing the said pipes and each in communication with one of the trays or troughs and the trays or troughs each in communication with the channel in the corresponding section and a coil in each tray or trough in communication with the pipe in the corresponding channel a liquid-collector in communication with the said coils, valves to regulate the flow of the liquefied gaseous mixture from each of the said coils to the said liquid-collector a filter in communication with the said liquid-collector and with the uppermost of the said trays or troughs a float in the lowest of the said trays or troughs, electric contacts to act in conjunction with the said float, a gas-collector in communication with the said channels and furnished with a triangular opening for the escape of gases not desired to be collected, a piston weighted to regulate the escape of gases thereby, valves to regulate the number of the said channels which are allowed to communicate at any time with the outlet for gases which it is not desired to collect and the number of the said channels from which the gases are to be conducted to the places to which the said gas-collector may be connected, all for the purpose hereinbefore described.

29. An apparatus for the separation of a gaseous mixture into its constituents by the liquefaction and subsequent evaporation or fractional distillation of such gaseous mixture in the manner hereinbefore described consisting essentially in the combination of an exchanger and liquefier containing respectively corresponding numbers of sections and trays or troughs varying as to number according to the degree of purity desired in the gases to be separated and collected, the sections containing pipes for the passage of the gaseous mixture to be liquefied and channels containing the said pipes and each in communication with one of the trays or troughs, and the trays or troughs each in communication with the channel in the corresponding section and a coil in each tray or trough in communication with the pipe in the corresponding channel, a liquid-collector in communication with the said coils, valves to regulate the flow of liquefied gaseous mixture from each of the said coils to the said liquid-collector, a filter in communication with the said liquid-collector and with the uppermost of the said trays or troughs, a valve to shut off the said filter from the uppermost tray or trough, a float in the lowest of the said trays or troughs, electric contacts to act in conjunction with the said float, a gas-collector in communication with the said channels and provided with an outlet for gases not desired to be collected, means to regulate the escape of gases thereby, means to regulate the number of the said channels which are allowed to communicate at any time with the outlet for gases which it is not desired to collect and the number of the said channels from which gases are to be conducted to the places to which the said gas-collector may be connected all for the purposes hereinbefore described.

30. An apparatus for the separation of a gaseous mixture into its constituents by the liquefaction and subsequent evaporation or fractional distillation of such gaseous mixture in the manner hereinbefore described consisting essentially in the combination of an exchanger and liquefier containing respectively numbers of sections and trays or troughs varying as to number according to the degree of purity desired in the gases to be separated and collected, the sections containing pipes for the passage of the gaseous mixture to be liquefied and channels containing the said pipes and each in communication with one of the trays or troughs and the trays or troughs each in communication with the channel in the corresponding section and a coil in each tray or trough in communication with the pipe in the corresponding channel, a liquid-collector in communication with the said coils, valves to regulate the flow of liquefied gaseous mixture

from each of the said coils to the said liquid-collector, a filter in communication with the uppermost of the said trays or troughs, a float in the lowest of the said trays or troughs electrical contacts to act in conjunction with the said float means to permit inspection of the interiors of the said troughs or trays a gas-collector in communication with the said channels and provided with an outlet for gases not desired to be collected a piston to regulate the escape of gases thereby, means to regulate the number of the said channels which are allowed to communicate at any time with the outlet for gases which it is not desired to collect and the number of the said channels from which gases are to be conducted to the places to which the said gas-collector may be connected for the purposes hereinbefore described.

31. An apparatus for the separation of a gaseous mixture into its constituents by the liquefaction and subsequent evaporation or fractional distillation of such gaseous mixture in the manner hereinbefore described consisting essentially in the combination of an exchanger and liquefier containing respectively numbers of sections and trays or troughs varying as to number according to the degree of purity desired in the gases to be separated and collected, the sections containing pipes for the passage of the gaseous mixture to be liquefied and channels containing the said pipes and each in communication with one of the trays or troughs and the trays or troughs each in communication with the channel in the corresponding section and a coil in each tray or trough in communication with the pipe in the corresponding channel, a liquid-collector in communication with the said coils, valves to regulate the flow of liquefied gaseous mixture from each of the said coils to the said liquid-collector, a filter in communication with the uppermost of the said trays or troughs, means to regulate the flow of liquefied gaseous mixture to the said filter, means to shut off the said filter from the uppermost tray or trough, a float in the lowest of the said trays or troughs, electrical contacts to act in conjunction with the said float, means to permit inspection of the interiors of the said troughs or trays, a gas-collector in communication with the said channels, and provided with an outlet for gases not desired to be collected a piston to regulate the escape of gases thereby, means to regulate the number of the said channels which are allowed to communicate at any time with the outlet for gases which it is not desired to collect and the number of the said channels from which gases are to be conducted to the places to which the said gas-collector may be connected for the purposes hereinbefore described.

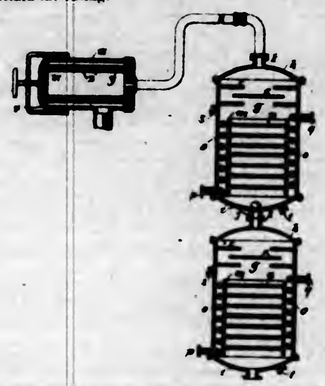
32. An apparatus for the separation of a gaseous mixture into its constituents by the liquefaction and subsequent evaporation or fractional distillation of such gaseous mixture in the manner hereinbefore described consisting essentially in the combination of an exchanger and liquefier containing respectively numbers of sections and trays or troughs varying as to number according to the degree of purity desired in the gases to be separated and collected, the sections containing pipes for the passage of the gaseous mixture to be liquefied and channels containing the said pipes and each in communication with one of the trays or troughs and the trays or troughs each in communication with the channel in the corresponding section and a coil in each trough or tray in communication with the pipe in the corresponding channel a liquid-collector in communication with the said coils, valves to regulate the flow of liquefied gaseous mixture from each of the said coils to the said liquid-collector, filters in communication with the uppermost of the said troughs or trays means to regulate the flow of liquefied gaseous mixture to the said filters, means to shut off the said filters from the uppermost tray or trough a float in the lowest of the said trays or troughs, electrical contacts to act in conjunction with the said float means to permit inspection of the interiors of the said troughs or trays, a gas-collector in communication with the said channels and provided with an outlet for gases not desired to be collected, a piston to regulate the escape of gases thereby means to regulate the number of the said channels which are allowed to communicate at any time with the outlet for gases which it is not desired to collect and the number of the said channels from which gases are to be conducted to the places to which the said gas-collector may be connected for the purposes hereinbefore described.

34. An apparatus for the separation of a gaseous mixture into its constituents by the liquefaction and subsequent evaporation or fractional distillation of such gaseous mixture in the manner hereinbefore described consisting essentially in the combination of an exchanger and liquefier containing respectively corresponding numbers of sections and trays or troughs varying as to number according to the degree of purity desired in the gases to be separated and collected, the sections containing pipes for the passage of the gaseous mixture to be liquefied and channels containing the said pipes and each in communication with one of the trays or troughs and the trays or troughs each in communication with the channel in the corresponding section and a coil in each tray or trough in communication with the pipe in the corresponding channel, a liquid-collector in communication with the said coils, valves to regulate the flow of liquefied gaseous mixture from each of the said coils to the said liquid-collector, filters in communication with the said liquid-collector and with the uppermost of the said trays or troughs valves to shut off the said filters from the uppermost tray or trough, a float in the lowest of the said trays or troughs, electric contacts to act in conjunction with the said float, a gas-collector in communication with the said channels and furnished with an opening for the escape of gases not desired to be collected, means to regulate the escape of gases thereby, valves to regulate the number of the said channels which are allowed to communicate at any time with the outlet for gases which it is not desired to collect and the number of the said channels from which gases are to be conducted to the places to which the said gas-collector may be connected all for the purposes hereinbefore described.

35. An apparatus for the separation of a gaseous mixture into its constituents by the liquefaction and subsequent evaporation or fractional distillation of such gaseous mixture in the manner hereinbefore described consisting essentially in the combination of an exchanger and liquefier containing respectively numbers of sections and trays or troughs varying as to number according to the degree of purity desired in the gases to be separated and collected, the sections containing pipes for the passage of the gaseous mixture to be liquefied and channels containing the said pipes and each in communication with one of the trays or troughs and the trays or troughs each in communication with the channel in the corresponding section and a coil in each tray or trough in communication with the pipe in the corresponding channel, a liquid-collector in communication with the said coils, valves to regulate the flow of the liquefied gaseous mixture from each of the said coils to the said liquid-collector filters in communication with the said liquid-collector and with the uppermost of the said trays or troughs, valves to shut off the said filters from the uppermost tray or trough, a float in the lowest of the said trays or troughs, electric contacts to act in conjunction with the said float a gas-collector in communication with the said channels and furnished with an opening for the escape of gases not desired to be collected automatic means to regulate the escape of gases thereby, valves to regulate the number of the said channels which are allowed to communicate at any time with the outlet for gases which it is not desired to collect and the number of the said channels from which gases are to be conducted to the places to which the said gas-collector may be connected, all for the purposes hereinbefore described.

809,219. APPARATUS FOR DEHYDRATING COMPRESSED GASES. RAOUL P. PICTET, Steglitz, Germany. Filed July 25, 1903. Serial No. 166,949.

Claim.—1. A dehydrater for drying compressed gas, air for example, consisting in a chamber to contain liquid and furnished with an inlet for the gas to be dried and an outlet for the dried gas, a tubular coil for the passage of cooling liquid mounted in the said chamber and immersed in the liquid therein and a casing also supported in the said chamber and immersed in the liquid therein and provided with partitions having openings for the gas to pass through in ascending within the casing.



2. Dehydraters in series for drying compressed gas, air for example, with the outlet of one connected to the inlet of another and each consisting of a chamber to contain liquid and furnished with an inlet for the gas to be dried and an outlet for the dried gas, a tubular coil for the passage of cooling liquid mounted in the said chamber and immersed in the liquid therein and a casing also supported in the said chamber and immersed in the liquid therein and provided with partitions having openings for the gas to pass through in ascending within the casing.

3. Dehydraters in series for drying compressed gas, air for example, with the outlet of one connected to the inlet of another and containing liquids cooled to different temperatures and each consisting of a chamber to contain liquid and furnished with an inlet for the gas to be dried and an outlet for the dried gas, a tubular coil for the passage of cooling liquid mounted in the said chamber and immersed in the liquid therein and a casing also supported in the said chamber and provided with partitions having openings for the gas to pass through in ascending within the casing.

4. Dehydraters in series for drying compressed gas air for example, each containing cooled liquid cooled to a temperature different from that in another with the outlet of one, containing liquid cooled to one temperature connected to the inlet of another containing a liquid cooled to another temperature and each consisting of a chamber to contain liquid and furnished with an inlet for the gas to be dried and an outlet for the dried gas, a tubular coil for the passage of cooling liquid mounted in the said chamber and immersed in the liquid therein and a casing also supported in the said chamber and immersed in the liquid therein and provided with partitions having openings for the gas to pass through in ascending within the casing.

5. Dehydraters in series for drying compressed gas air for example, each containing cooled liquid and one containing liquid cooled to a lower temperature than the liquid in another with the outlet of the one containing liquid cooled to one temperature connected to the inlet of another containing liquid cooled to a lower temperature and each consisting of a chamber to contain liquid and furnished with an inlet for the gas to be dried and an outlet for the dried gas, a tubular coil for the passage of cooling liquid mounted in the said chamber and immersed in the liquid therein and a casing also supported in the said chamber and immersed in the liquid therein and provided with partitions having openings for the gas to pass through in ascending within the casing.

6. Two dehydraters in series for drying compressed gas, air for example, with the outlet of the one connected to the inlet of the other and each consisting of a chamber to contain liquid and furnished with an inlet for the gas to be dried and an outlet for the dried gas, a tubular coil for the passage of cooling liquid mounted in the said chamber and immersed in the liquid therein and a casing also supported in the said chamber and immersed in the liquid therein and provided with partitions having openings for the gas to pass through in ascending within the casing.

7. Two dehydraters in series for drying compressed gas, air for example, with the outlet of the one connected to the inlet of the other and containing liquids cooled to different temperatures and each consisting of a chamber to contain liquid and furnished with an inlet for the gas to be dried and an outlet for the dried gas, a tubular coil for the passage of cooling liquid mounted in the said chamber and immersed in the liquid therein and a casing also supported in the said chamber and provided with partitions having openings for the gas to pass through in ascending the casing.

8. Two dehydraters in series for drying compressed gas, air for example, each containing cooled liquid cooled to a temperature different from that in the other, with the outlet of one containing liquid cooled to one temperature connected to the inlet of the other containing a liquid cooled to another temperature and each consisting of a chamber to contain liquid and furnished with an inlet for the gas to be dried and an outlet for the dried gas, a tubular coil for the passage of cooling liquid mounted in the said chamber and immersed in the liquid therein and a casing also supported in the said chamber and immersed in the liquid therein and provided with partitions having openings for the gas to pass through in ascending within the casing.

9. Two dehydraters in series for drying compressed gas, air, for example each containing cooled liquid and one containing liquid cooled to a lower temperature than the liquid in the other, with the outlet of the one containing liquid cooled to one temperature connected to the inlet of the other containing liquid cooled to a lower temperature and each consisting of a chamber to contain liquid and furnished with an inlet for the gas to be dried and an outlet for the dried gas, a tubular coil for the passage of cooling liquid mounted in the said chamber and immersed in the liquid therein, and a casing also supported in the said chamber and immersed in the liquid therein and provided with partitions having openings for the gas to pass through in ascending within the said casing.

10. Two dehydraters in series for drying compressed gas, air for example, each containing cooled liquid and one containing liquid cooled to a temperature of about 0° centigrade and the other containing liquid cooled to a lower temperature and with the outlet of the one containing liquid cooled to a temperature af about 0° centigrade connected to the inlet of the other containing liquid cooled to a lower temperature and each consisting of a chamber to contain liquid and furnished with an inlet for the gas to be dried and an outlet for the dried gas, a tubular coil for the passage of cooling liquid mounted in the said chamber and immersed in the liquid therein and a casing also supported in the said chamber and immersed in the liquid therein and provided with partitions having openings for the gas to pass through in ascending within the casing.

11. Two dehydraters in series for drying compressed gas, air for example, each containing cooled liquid and one containing liquid cooled to a temperature of about 0° centigrade and the other containing liquid cooled to a temperature of about from —20° centigrade to —40° centigrade and with the outlet of the one containing liquid cooled to a temperature of about 0° centigrade connected to the inlet of the other containing liquid cooled to the temperature of about from —20° centigrade to —40° centigrade and each consisting of a chamber to contain liquid and furnished with an inlet for the gas to be dried and an outlet for the dried gas, a tubular coil for the passage of cooling liquid mounted in the said chamber and immersed in the liquid therein and a casing also supported in the said chamber and immersed in the liquid therein and provided with partitions having openings for the gas to pass through in ascending within the casing.

809,220. COLLECTOR-RING. HARRY G. REIST, Schenectady, N. Y., assignor to General Electric Company, a Corporation of New York. Filed Apr. 23, 1904. Serial No. 204,316.

Claim.—1. A collector-ring cut away to form a flexible part, and a supporting-stud carried by said part.

2. A collector-ring having circumferentially-extending slots

from each of the said coils to the said liquid-collector, a filter in communication with the uppermost of the said trays or troughs, a float in the lowest of the said trays or troughs electrical contacts to act in conjunction with the said float means to permit inspection of the interiors of the said troughs or trays a gas-collector in communication with the said channels and provided with an outlet for gases not desired to be collected a piston to regulate the escape of gases thereby, means to regulate the number of the said channels which are allowed to communicate at any time with the outlet for gases which it is not desired to collect and the number of the said channels from which gases are to be conducted to the places to which the said gas-collector may be connected for the purposes hereinbefore described.

31. An apparatus for the separation of a gaseous mixture into its constituents by the liquefaction and subsequent evaporation or fractional distillation of such gaseous mixture in the manner hereinbefore described consisting essentially in the combination of an exchanger and liquefier containing respectively numbers of sections and trays or troughs varying as to number according to the degree of purity desired in the gases to be separated and collected, the sections containing pipes for the passage of the gaseous mixture to be liquefied and channels containing the said pipes and each in communication with one of the trays or troughs and the trays or troughs each in communication with the channel in the corresponding section and a coil in each tray or trough in communication with the pipe in the corresponding channel, a liquid-collector in communication with the said coils, valves to regulate the flow of liquefied gaseous mixture from each of the said coils to the said liquid-collector, a filter in communication with the uppermost of the said trays or troughs, means to regulate the flow of liquefied gaseous mixture to the said filter, means to shut off the said filter from the uppermost tray or trough, a float in the lowest of the said trays or troughs, electrical contacts to act in conjunction with the said float, means to permit inspection of the interiors of the said troughs or trays, a gas-collector in communication with the said channels and provided with an outlet for gases not desired to be collected means to regulate the escape of gases thereby, means to regulate the number of the said channels which are allowed to communicate at any time with the outlet for gases which it is not desired to collect and the number of the said channels from which gases are to be conducted to the places to which the said gas-collector may be connected for the purposes hereinbefore described.

32. An apparatus for the separation of a gaseous mixture into its constituents by the liquefaction and subsequent evaporation or fractional distillation of such gaseous mixture in the manner hereinbefore described consisting essentially in the combination of an exchanger and liquefier containing respectively numbers of sections and trays or troughs varying as to number according to the degree of purity desired in the gases to be separated and collected, the sections containing pipes for the passage of the gaseous mixture to be liquefied and channels containing the said pipes and each in communication with one of the trays or troughs and the trays or troughs each in communication with the channel in the corresponding section and a coil in each trough or tray in communication with the pipe in the corresponding channel a liquid-collector in communication with the said coils, valves to regulate the flow of liquefied gaseous mixture from each of the said coils to the said liquid-collector, filters in communication with the uppermost of the said troughs or trays means to regulate the flow of liquefied gaseous mixture to the said filters, means to shut off the said filters from the uppermost trough or tray a float in the lowest of the said trays or troughs, electrical contacts to act in conjunction with the said float, means to permit inspection of the interiors of the said troughs or trays, a gas-collector in communication with the said channels and provided with an outlet for gases not desired to be collected means to regulate the escape of gases thereby, means to regulate the number of the said channels which are allowed to communicate at any time with the outlet for gases which it is not desired to collect and the number of the said channels from which gases are to be conducted to the places to which the said gas-collector may be connected for the purposes hereinbefore described.

33. An apparatus for the separation of a gaseous mixture into its constituents by the liquefaction and subsequent evaporation or fractional distillation of such gaseous mixture in the manner hereinbefore described consisting essentially in the combination of an exchanger and liquefier containing respectively numbers of sections and trays or troughs varying as to number according to the degree of purity desired in the gases to be separated and collected, the sections containing pipes for the passage of the gaseous mixture to be liquefied and channels containing the said pipes and each in communication with one of the trays or troughs and the trays or troughs

formed in it to give flexible portions, and supporting-studs engaging said portions.

3. In combination, a cylindrical support, a collector-ring, flexible portions carried thereby, and means extending between said flexible portions and said support and normally holding said portions under tension.

4. In combination, a support, a collector-ring, flexible members secured thereto, and means extending between said support and said flexible members holding said flexible members under tension when the collector-ring is cold.

5. In combination, a support, a collector-ring formed with flexible parts, and means for securing the collector-ring to the support in such a manner that the flexible parts are put in an initial tension which decreases when the collector-ring expands.

6. In combination, a support, a collector-ring formed with flexible parts, and a device extending between said support and said flexible parts by which the latter are put under initial tension.

7. In combination, an annular collector-ring formed with slots in it to give flexible strips or portions, each of which is connected at its ends to the collector-ring proper and is formed with a socket located between its ends, pins or studs secured in said sockets and extending radially inward from the collector-ring, and a cylindrical support for the collector-ring having an engaging surface or surfaces against which the inner ends of the studs or pins bear, the parts being so proportioned and arranged that when the collector-ring is at normal atmospheric temperature the flexible portions are deflected outward.

8. An annular collector-ring having circumferentially-extending slots formed therein to give flexible portions, and supporting means engaging said flexible portions.

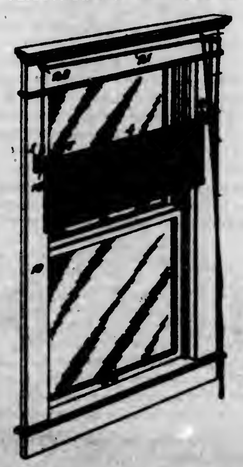
9. A collector-ring formed with one or more flexible strips or portions each secured at its ends to the collector-ring proper, and a supporting device engaging each of said strips between its ends.

10. A collector-ring formed with one or more flexible strips or portions each secured at its ends to the collector-ring proper and having a socket formed in it, and a supporting pin or stud located in said socket.

11. In combination, a cylindrical support, a collector-ring formed with flexible strips, each of said strips being secured at its ends to the collector-ring proper, and a device for securing the collector-ring to the support extending between said support and each flexible strip.

12. In combination, a cylindrical support, a collector-ring formed with flexible strips, each of said strips being secured at its ends to the collector-ring proper, and means for securing the collector-ring to said support extending between said support and the flexible strips, said means being arranged to deflect the strips outward in the normal condition of the apparatus.

809,221. **WINDOW-SHADE HOLDER.** JOHN RENNER, Burlington, Iowa. Filed Feb. 24, 1905. Serial No. 247,154.



Claim.—1. In a device of the class described, the combination of a bracket having a bearing portion and provided therein with a journal-receiving opening, said bracket being also provided with an entrance-slot, and a locking-plate mounted on the bearing portion of the bracket and provided with a journal-receiving opening and having an entrance-slot, said locking-plate being movable to carry its entrance-slot into and out of register with that of the bracket.

2. In a device of the class described, the combination with a curtain-roller, of a bracket having a concavo-convex bearing portion and provided therein with a journal-receiving opening, said bracket being also provided with an entrance-slot, and a concavo-convex locking-plate fitted on the bearing portion of the bracket and provided with an opening and having an entrance-slot, said locking-plate being capable of a rotary movement to carry its entrance-slot into and out of register with that of the bearing-bracket.

3. In a device of the class described, the combination with a curtain-roller, of a bracket having a concavo-convex bearing portion presenting an inner convex face to the curtain-roller and having an outer concave face, said bracket having an opening and an entrance-slot thereto, a concavo-convex locking-plate arranged on the outer face of the bearing portion of the bracket and provided with an opening, and an entrance-slot thereto, and lugs securing the locking-plate to the bracket, said lugs extending from one of the parts and engaging the other.

4. In a device of the class described, the combination with a curtain-roller, of a substantially L-shaped bracket provided at its inner face with a tongue extending across the angle of the bracket and forming a guide-opening.

5. In a device of the class described, the combination with brackets adapted to support a window-shade, and a curtain-cord provided with two branches, of guides located at opposite sides of the window, one of the guides being provided with spaced inner, outer, and intermediate guide-eyes located different distances from the window and arranged to equalize the friction, the inner eye receiving one of the branches, and the other branch being passed through the intermediate and outer eyes.

6. In a device of the class described, the combination with brackets adapted to support a window-shade, and a curtain-cord provided with branches, of guides located at opposite sides of the window, one of the guides being constructed of a single piece of metal disposed substantially horizontally and provided at its inner end with a shank for connecting it to a window-frame and coiled at intervals to form spaced inner, outer, and intermediate guide-eyes, the inner eye receiving one of the branches of the curtain-cord and the other branch being passed through the intermediate and outer eyes.

7. In a device of the class described, the combination with brackets adapted to support a window-shade, and a curtain-cord, of guides for the curtain-cords, one of the guides being constructed of a single piece of metal coiled at intervals to form spaced inner, outer, and intermediate guide-eyes for the curtain-cord, the inner and outer eyes being vertical and arranged in longitudinal and transverse planes, and the intermediate eye being disposed horizontally.

809,222. **WATER-CLOSET.** CHARLES H. ROLLINS, Watertown, Mass. Filed May 27, 1903. Serial No. 159,606.

Claim.—1. For employment with a water-closet, a seat having two integral rearwardly-projecting arms, a cover having an integral arm which projects into and fills the space between the said arms on the seat, and a rod or pintle passing through apertures in all of said arms and adapted to be connected to a closet, said rod or pintle being covered and concealed substantially from end to end by the cover and seat.

2. For employment with a water-closet, a seat having one or more rearwardly-projecting arms, a cover adapted to rest upon the top of said seat and having an integral arm which projects rearwardly and downwardly into the plane of the last-mentioned arm or arms, and a rod passing through said arms and adapted to be connected to the closet, said arms being contiguous so as to substantially cover and conceal the rod from end to end thereof.

3. For employment with a water-closet, the combination of a seat and a cover, said seat and cover having non-metallic arms, the ends of which are in the same plane and substantially contiguous, said arms having alined apertures, a straight rod or pintle passed through said apertures and covered substantially from end to end by said arms.

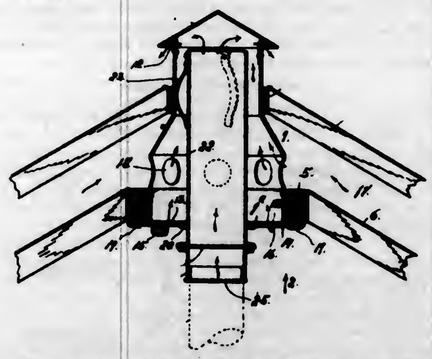
4. For employment with a water-closet, a seat having two integral rearwardly-projecting arms, a cover having an integral arm which projects downward between the arms of said seat and fills the space between the said arms, all of said arms having alined apertures, a straight rod or pintle passing through said apertures and covered substantially from end to end by said arms, and studs by which said pintle or rod may be connected to said closet.

5. In combination with a water-closet, upright studs at the sides thereof, non-metallic casings inclosing said studs, a rod supported by said studs, and a non-metallic seat and a non-metallic cover having apertures for receiving and concealing said rod, at all points between said studs.

6. In combination with a water-closet, non-metallic knobs secured to said closet at the rear sides of the top thereof, studs loose within said knobs, a metallic rod having its ends terminating in said knobs and studs, and a non-metallic seat and a non-metallic cover hinged to and concealing said rod, whereby no metallic surfaces are exposed.

7. In combination with a water-closet, upright metallic studs secured to said closet, non-metallic knobs or casings entirely concealing said studs, a metallic rod supported by said studs, a non-metallic seat having separated arms apertured to receive said rod and held against lateral movement by said knobs or casings, and a non-metallic cover having a downwardly-projecting arm which extends between the arms of the seat and which is apertured to receive said rod.

809,223. **COMBINED SMOKE-FLUE AND VENTILATING DEVICE.** CHARLES C. ROTH, Denver, Colo., assignor to The Denver Tent and Awning Company, Denver, Colo. Filed Dec. 27, 1904. Serial No. 238,548.



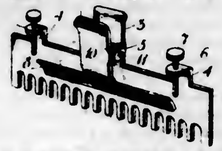
Claim.—1. In a structure having a roof and fly, a combined smoke-flue and ventilating device, consisting of a smoke-flue and a surrounding ventilating-flue, both flues being open-ended and forming independent passages between the atmosphere and the interior of the structure, and each flue being provided with suitable means for controlling said passage, the ventilating-flue also communicating with the space between the roof and fly.

2. The combination with a structure provided with a roof and fly, of a ventilating-flue mounted therein and passing through the roof and fly, the said flue communicating with the atmosphere at the top, the interior of the structure at the bottom, and with the space between the roof and fly intermediate its extremities, and an open-ended, damper-controlled smoke-flue centrally located in the ventilating-flue, a suitable space being left between the two flues, substantially as described.

3. The combination of a structure having a roof and fly respectively, provided with central openings, frames surrounding said openings, a ventilating-flue passing through the said openings and fastened to the frames, the flue having communication with the atmosphere at the top and with the interior of the structure at the bottom, and with the space between the roof and fly intermediate its extremities, a cut-off slide for controlling the bottom opening, and an open-ended flue centrally located in the ventilating-flue for the purpose set forth.

4. The combination with a structure having a roof and fly of a flue open at the top and bottom, a slide for controlling the bottom opening, the said flue communicating with the atmosphere at the top the inside of the structure at the bottom and the space between the roof and fly intermediate its extremities another flue centrally located in the ventilating-flue, guides interposed between the two flues at the top for centering the central flue which is fitted tightly into the bottom of the ventilating-flue, the central flue being open-ended and having a mesh-covered thimble inserted in its lower extremity.

809,224. **RAZOR-GUARD.** EDWARD A. SCHREIBER and JOSEPH O. KLEE, Rochester, N. Y. Filed May 18, 1905. Serial No. 261,000.



Claim.—1. A razor-guard comprising a plate having teeth on one side, adjusting-screws carried by the plate to bear against the rear side of a razor-blade and a spring-pressed clamp-clip pivotally connected to the said plate to clamp a razor-blade between it and the said plate, substantially as described.

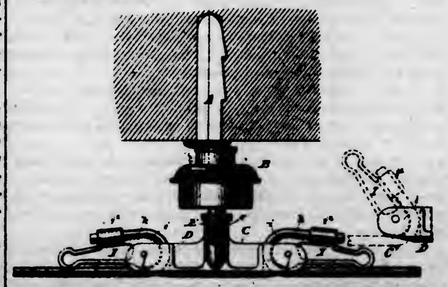
2. A razor-guard comprising a plate to bear against one side of a razor-blade, provided at one side with teeth and at the opposite side with outwardly-extending arms, adjusting-screws carried by two of said arms near the ends of said plate to bear against the back of the razor-blade, a clamp-clip having an arm pivotally connected to the other arm of the said plate and a spring between the said arms and normally closing the clamp-clip against the plate, substantially as described.

809,225. **PROCESS OF MANUFACTURING ARTIFICIAL PAVING-STONES.** WILHELM SCHUMACHER, Oberdollendorf, Germany. Filed Dec. 11, 1903. Serial No. 184,842.

Claim.—1. The herein-described method of producing artificial paving-stones, which consists in first heating bauxite at a high temperature until it is perfectly sintered, then reducing it to small pieces of a suitable fineness, next mixing it with a ground binding material (clay, cement, asphalt and the like), afterward moistening the mixture with water and molding it to stones and finally burning the stones.

2. The herein-described method of producing artificial paving-stones, which consists in first heating bauxite with the addition of a flux at a high temperature until it is perfectly sintered, then reducing it to small pieces of a suitable fineness, next mixing it with a ground binding material (clay, cement, asphalt and the like), afterward moistening the mixture with water and molding it to stones and finally burning the stones.

809,226. **WIRE-CARRIER.** FRANK L. SESSIONS, Columbus, Ohio, assignor to Joseph A. Jeffrey, Columbus, Ohio. Filed July 17, 1903. Serial No. 165,976.



Claim.—1. A wire-carrier having a body part provided with a wire-passage and an opposing gripping element pivotally connected to the body part and adjusted by means of a handle or projecting arm having a projection with a passage-way through it for receiving the end of the wire.

2. A wire-carrier having a body part provided with a wire-passage and an opposing gripping element pivotally connected to the

body part and adjusted by means of a handle or projecting arm having a projection normally above the main line of the wire with a passage-way through it for receiving the end of the wire.

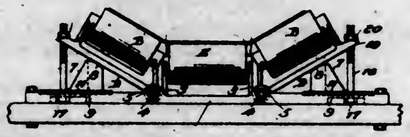
3. A wire-carrier having a body part formed with a vertically-arranged passage-way through which can be passed a bent portion of the wire, and a gripper movably connected to the body part and having a wire-gripping part and means for adjusting the wire-gripping part adapted to be engaged at its free end by the line-wire substantially as set forth whereby the trolley-pressure against the line-wire tends to increase the locking or clamping pressure between the gripping elements.

4. A wire-carrier having a body part with an aperture having a wall or abutment on a line inclined to the main line of the wire, and a pivoted gripper pivotally connected to the body part having a wire-gripping part and means for adjusting the wire-gripping part adapted to engage the line-wire at a point some distance from its clamped portion.

5. A wire-carrier having a body part provided with a wire-passage and an opposing gripping element pivotally connected with the body part and adjusted by means of a handle or lever-arm provided with means for receiving and holding the end of the wire to be clamped, substantially as set forth.

6. A wire-carrier having a body part provided with a wire-passage and an opposing gripping element pivotally connected with the body part and adjusted by means of a handle or lever-arm, said handle being provided with a device for receiving the end of the wire and carrying it around said pivotal connection as the handle is adjusted to cause the gripping of the wire, substantially as set forth.

809,227. CONVEYER-BELT SUPPORT. ARCHIBALD W. F. STECKEL, Columbus, Ohio, assignor to Joseph A. Jeffrey, Columbus, Ohio. Filed June 20, 1904. Serial No. 213,402.



Claim.—1. In a conveyer, a belt-support consisting of the combination of two inclined pulleys, a movable carrier for each of said pulleys operable up and down in planes transverse to the belt, an intermediate support for the belt independent of said pulleys, and means for operating said carriers to adjust said inclined pulleys relative to said intermediate support.

2. In a conveyer, a belt-support consisting of the combination of two inclined pulleys, a carrier for each of said pulleys mounted on a hinge or fulcrum, the axis of which is longitudinal of the belt, an intermediate support for the belt independent of said pulleys, and means for adjusting the said carriers around their longitudinal axes to change the positions of said pulleys relative to said intermediate support.

3. In a conveyer, a belt-support consisting of the combination of two inclined pulleys, a carrier for each of said pulleys mounted on a longitudinal hinge or fulcrum and having inner and outer bearings for the inner and outer ends of the pulley shafts or journals, an intermediate support for the belt, and means for adjusting the said carriers around their longitudinal hinges.

4. In a conveyer, a belt-support consisting of the combination of two inclined pulleys, a carrier for each of said pulleys, adjustable up and down, and transversely-movable slides engaging said carriers for adjusting the latter.

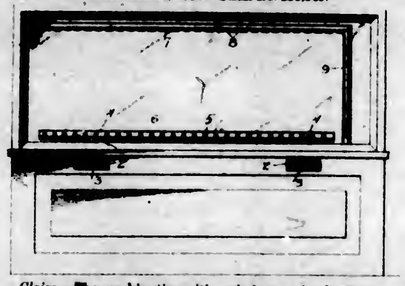
5. In a conveyer, a belt-support consisting of the combination of two inclined pulleys, a carrier for each of said pulleys mounted on a longitudinal axis or fulcrum, means for forcing and holding said carriers downward, and means for forcing and holding said carriers upward.

6. In a conveyer, the combination of two inclined pulleys, a base, a carrier for each of said pulleys, movably supported on a hinge or fulcrum on said base, and inwardly and outwardly movable slides interposed between said carriers and the base.

7. In a conveyer, a belt-support consisting of the combination of two inclined pulleys, a base, a carrier for each of said pulleys, movably supported on a hinge or fulcrum on said base, inwardly and outwardly movable slides interposed between said carriers and the base, and connections between the base and said carriers for holding the latter downward.

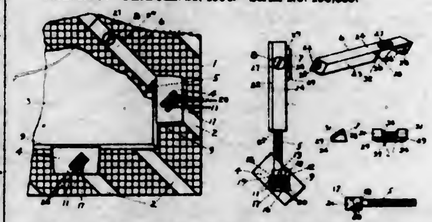
8. In a mechanism of the class described, the combination with a suitable frame and a conveyer-belt arranged thereon, of a plurality of pulleys designed to support the central portion of said belt, pulleys arranged at the ends of said central pulleys designed to support the edges of said belt, means for adjusting said end pulleys to diagonal planes, and means for locking the same in such positions, substantially as set forth.

809,228. WINDOW-VENTILATOR. AUGUSTUS A. STEPHENS, Bellaire, Ohio. Filed Oct. 28, 1904. Serial No. 230,240.



Claim.—The combination with a window-casing having screened openings beneath its bottom which openings lead from the outside; of a perforated tubing arranged within the casing at the bottom thereof, said tubing having a depending pipe extension at each end adapted to extend through the bottom of the casing and having flaring mouths fitting over the corresponding openings beneath the bottom of the casing; a second perforated tubing arranged at the top of and within the casing and independent of the other tubing, the perforations of the latter tubing being arranged in the bottom thereof, a pipe leading from one end of the upper tubing through the flooring of the casing, a fan in communication with the lower end of the last-named pipe, and means for operating the fan to draw warm air out of the casing through the tubing, the pipe and the fan.

809,229. PRINTING-PLATE HOLDER. EDWIN R. STORM, New York, N. Y. Filed Jan. 21, 1904. Serial No. 190,089.



Claim.—1. In a holder for printing-plates the combination of a block having grooves adapted to receive and hold one or more plate-clamps and adjustable plate-clamps held in the grooves, each of said plate-clamps consisting of a base-piece adapted to be held in the grooves, a face-piece having a member extending into the groove and adapted to act with the head of a screw to hold the face-piece to position on the grooved block, and an adjusting-screw adapted to move the face-piece and the printing-plate over limited distances and hold the face-piece and printing-plate securely to the block at any point of such limited distances.

2. In a holder for printing-plates the combination of a block having grooves adapted to receive and hold one or more plate-clamps, a base-piece adapted to be secured within one of the grooves, an adjusting-screw held by the base-piece a member formed to extend into the grooves and engage with the adjusting-screw, and a movable face-piece formed integrally with the said member controlled by and moving with the adjusting-screw.

3. In a holder for printing-plates the combination of a block having grooves adapted to receive one or more plate-clamps, a base-piece adapted to be inserted at any point of the groove, a sliding member working within said base-piece, a set-screw adapted to act with the sliding member and hold the base-piece securely to any point of the groove, an adjusting-screw working within the base-piece and a face-piece with a holding edge thereon, controlled by the adjusting-screw.

4. In a holder for printing-plates, the combination of a grooved block, an adjusting-screw working within a threaded hole, a shoulder formed on the adjusting-screw, a face-piece working on the top surface of the grooved block, a member on the face-piece extending into the groove formed in the block, a surface adapted to receive the shoulder formed on the adjusting-screw, one or more slots in the face-piece adapted to admit the passage of an operating-bar and holes in the head of the adjusting-screw adapted to receive the end of an operating-bar.

5. In a holder for printing-plates the combination of a grooved block, a face-piece working on the top surface of the grooved block, a holding edge on the face-piece, a member on the face-piece extending into the groove formed in the block, a surface formed on the member extending into the groove, a shoulder formed on an adjusting-screw said shoulder being adapted to work against the surface formed on the member extending into the groove and an adjusting-screw having a shoulder thereon adapted to work against the face-piece and carry it along the lineal distance traversed by the head of the screw.

6. In a holder for printing-plates the combination of a grooved block, a face-piece working on the surface of the grooved block, a member on the face-piece extending into and fitted to the groove, a recessed portion in the said member adapted to receive the head of an adjusting-screw, a surface in the recessed portion adapted to receive the shoulder formed at the head of the adjusting-screw, an adjusting-screw formed with a shoulder at the head adapted to fit against the surface formed in the recessed portion, a member having a threaded hole adapted to receive and hold the adjusting-screw and holes in the head of the adjusting-screw adapted to receive the end of an operating-bar.

7. In a holder for printing-plates the combination of a grooved block, a face-piece working on the surface of the grooved block, an adjusting-screw held rotatably within the groove and working in a threaded hole, a base-piece having a threaded hole adapted to receive the adjusting-screw, a head on the adjusting-screw and a member on the face-piece extending into the groove and adapted to act in conjunction with the head of the adjusting-screw to hold the face-piece to the groove.

8. In a holder for printing-plates the combination of a grooved block, a face-piece working on the surface of the grooved block, a base-piece having a threaded hole therein secured within the groove, an adjusting-screw held rotatably within the groove and working in the said threaded hole in the base-piece, a head on the adjusting-screw, a member on the face-piece extending into the groove, a face on the said member fitted to the side of the groove, a recessed portion adapted to receive the head of the adjusting-screw and hold the head of the said adjusting-screw against the side of the groove causing it to act in conjunction with the said member to hold the face-piece to the surface of the block.

9. In a holder for printing-plates the combination of a grooved block, a face-piece working on the surface of the grooved block, a base-piece with a threaded hole therein secured within the groove, adapted to receive an adjusting-screw, an adjusting-screw working in the threaded hole, a head on the adjusting-screw adapted to pass into and work against one side of the groove, a member on the face-piece extending into the groove and adapted to pass freely to one side of the stem of the adjusting-screw in entering or leaving the groove, and a wedge-shaped portion on the member extending into the groove adapted to pass between the head of the adjusting-screw and a side of the groove and act in conjunction with the head of the adjusting-screw to hold the face-piece to the grooved block.

10. In a holder for printing-plates the combination of a grooved block, a face-piece working on the surface of the grooved block a base-piece with one side conforming to a side of the groove and its opposite side formed to admit the insertion of the base-piece in the groove, a sliding member working in the base-piece, a set-screw working in the base-piece and the sliding member, and an adjusting-screw connecting the face-piece to the base-piece.

11. In a holder for printing-plates the combination of a grooved block, a face-piece working on the surface of the grooved block, a base-piece with one side conforming to a side of the groove and its opposite side formed to admit the insertion of the base-piece at any point of the groove, a recessed portion in the base-piece adapted to receive a sliding member, ways formed in the recessed portion, a sliding member within the recessed portion, lugs on the sliding member fitted to the said ways and a set-screw adapted to act in conjunction with the sliding member to hold the base-piece rigidly within the groove.

12. In a holder for printing-plates the combination of a grooved block, a face-piece working on the surface of the grooved block, a base-piece with a threaded hole therein adapted to enter and partly fill the groove, a recessed portion in the base-piece connecting with the threaded hole, an inclined face on the recessed portion, a sliding member working within the recessed portion provided with a threaded surface corresponding to the said threaded hole, an inclined face on the sliding member adapted to work against the inclined face on the recessed portion, and a set-screw working within the threaded hole in the base-piece and connecting the sliding member to the base-piece.

13. In a holder for printing-plates the combination of a grooved block, a face-piece working on the surface of the grooved block, a base-piece provided with a threaded hole and adapted to enter and partly fill the groove, a set-screw in the threaded hole, a recessed portion in the base-piece, a sliding member within the recessed portion provided with a threaded surface adapted to receive the set-screw, an inclined face on the sliding member and an inclined face on the recessed portion adapted to bear against the inclined face on the sliding member and force it to slide until the threaded surface can be engaged by the set-screw as and for the purposes described.

14. In a holder for printing-plates the combination of a grooved block, a face-piece working on the surface of the grooved block, a base-piece with one side conforming to a side of the groove and its opposite side formed to admit the insertion of the base-piece at any point of the groove, a recessed portion in the base-piece, a sliding member within the recessed portion having one side conforming to a side of the groove, an inclined face on the sliding member, an inclined face on the base-piece adapted to fit against the inclined face on the sliding member to force the sliding member to one side of the groove and the base-piece to the other side of the groove and a set-screw connecting the sliding member and the base-piece and adapted to force and hold the base-piece and sliding member against the sides of the groove.

15. In a holder for printing-plates the combination of a grooved block, a face-piece working on the surface of the grooved block, a base-piece adapted to enter and partly fill the groove, a side on the base-piece conforming to one side of the groove, a sliding member with a side conforming to the opposite side of the groove, a screw connecting the base-piece and the sliding member adapted to bring the sliding member in coöperation with the base-piece and hold the base-piece fixedly in the groove, said base-piece having a threaded hole adapted to receive an adjusting-screw, and an adjusting-screw connecting the face-piece and the base-piece.

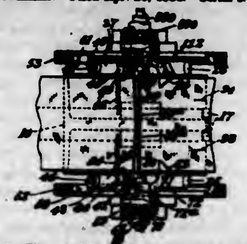
16. In a holder for printing-plates the combination of a grooved block, a base-piece adapted to enter and partly fill the groove, having one side conforming to a side of the groove and its opposite side formed to admit the insertion of the base-piece at any point of the groove, and provided with a recessed portion having ways therein, said base-piece being provided with a threaded hole adapted to receive an adjusting-screw and with a threaded hole partly cut away leading to the recessed portion and adapted to receive a set-screw, an inclined plane formed in the recessed portion, a sliding member within the recessed portion formed with an inclined face adapted to bear against the said inclined plane and provided with a threaded surface adapted to engage with a set-screw, lugs on the sliding member fitted to the said ways, a set-screw working partly in the base-piece and partly in the sliding member, an adjusting-screw provided with a head having a slot formed in the end and furnished with holes adapted to receive the end of an operating-bar, a face-piece working on the surface of the grooved block provided with one or more slots adapted to admit the passage of an operating-bar, a member on the face-piece extending into and fitted to one side of the groove, said member being provided with a recessed portion adapted to receive the head of the adjusting-screw and having a surface formed in the recessed portion adapted to receive the shoulder formed at the head of the adjusting-screw, a shoulder formed on the adjusting-screw between the head and the shank, and a holding edge formed on the face-piece adapted to bear against and hold the plate securely to the block.

17. In a holder for printing-plates the combination of a grooved block, a face-piece working on the surface of the grooved block, an adjusting-screw held rotatably within the groove, a member on the face-piece extending in the groove, a head on the screw adapted to bear against the said member to move the face-piece, a holding edge on the face-piece and one or more slots in the face-piece adapted to admit the passage of an operating-bar.

18. In a holder for printing-plates the combination of a grooved block, a face-piece working on the surface of the grooved block, an adjusting-screw held rotatably within the groove and working in

a threaded hole, a member in the groove having a threaded hole, a member on the face-piece extending in the groove, a head on the adjusting-screw adapted to engage with the member on the face-piece to control the movement of the said face-piece, a holding edge on the face-piece and one or more slots in the face-piece adapted to admit the passage of an operating-bar.

809,280. PAPER-BAG MACHINE. FREDERICK E. STRAFFORD, Rumford Falls, Me., assignor to Continental Paper Bag Company, a Corporation of Maine. Filed Apr. 26, 1904. Serial No. 204,903.



Claim.—1. The combination of a revoluble folding-bed, a pair of side clips thereon, a pair of nipper-trunnions, oppositely disposed with respect to the folding-bed, and having their axes substantially coincident with a straight line transverse the folding-bed and mounted for oscillation about the axis of said folding-bed, a pair of side nippers pivotally mounted in each nipper-trunnion for oscillation transverse the folding-bed, one member of each pair of side nippers mounted for oscillation toward and away from the other member of its respective pair, means to oscillate the nipper-trunnions about their own axis and about the axis of the folding-bed, means to oscillate the side nippers transverse the folding-bed, and means to oscillate one member of each pair of side nippers toward and away from the other member of its respective pair; all combined and operating together substantially as described.

2. The combination of a folding-bed, a pair of side clips 23, 24 thereon; a pair of defining-blades 38, 39 for defining the main transverse crease and vibrating upon axes substantially normal to the line of their defining edges, said axes forming acute angles respectively with the folding-bed, means for opening out the forward end of the bag-blank and folding the same down over the defining-blades, means for timing the side clips, the defining-blades and the folding means each with the others, and means for delivering the bag-blank to the folding-bed; all combined and operating together substantially as described.

3. The combination of a folding-bed, a pair of side clips 23, 24 thereon; two pairs of side nippers 62, 72 and 102, 112 vibrating inwardly and outwardly, with respect to the path of the bag-blank; nipper-trunnions 58, 580; said pairs of side nippers mounted for oscillation on said nipper-trunnions respectively; cams 71, 710 for closing the side nippers respectively; gears 79, 790, and segment-gears 80, 800 for oscillating the nipper-trunnions respectively; and plungers 70, 700 for vibrating the side nippers respectively; all combined and operating together substantially as described.

4. The combination of a revoluble folding-bed, a pair of side clips 23, 24 thereon; two pairs of side nippers 62, 72 and 102, 112 vibrating inwardly and outwardly, with respect to the path of the bag-blank; nipper-trunnions 58, 580; said pairs of side nippers mounted for oscillation on said nipper-trunnions respectively; cams 71, 710 for closing the side nippers respectively; gears 79, 790, and segment-gears 80, 800 for oscillating the nipper-trunnions respectively; plungers 70, 700 for vibrating the side nippers respectively; arms 34, 35 oscillating about the axis of the revoluble folding-bed, said arms having mounted thereon respectively nipper-trunnions 58, 580, cams 71, 710, and segment-gears 80, 800; all combined and operating together substantially as described.

5. The combination of a folding-bed 20, a pair of side clips 23, 24 thereon; two pairs of side nippers 62, 72 and 102, 112 vibrating inwardly and outwardly, with respect to the path of the bag-blank; nipper-trunnions 58, 580; said pairs of side nippers mounted for oscillation on said nipper-trunnions respectively; cams 71, 710 for closing the side nippers respectively; gears 79, 790 and segment-gears 80, 800 for oscillating the nipper-trunnions respectively; plungers 70, 700 for vibrating the side nippers respectively; oscillating arms 34, 35 having mounted thereon respectively nipper-trunnions 58, 580, cams 71, 710, and segment-gears 80, 800; all combined and operating together substantially as described.

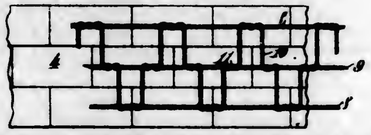
6. The combination of a folding-bed, side clips 23, 24 thereon, a pair of defining-blades for defining the main transverse crease, and vibrating upon axes substantially normal to the line of their defining edges, said axes forming acute angles respectively with the folding-bed; and means for folding the upper plies of the bag-blank over the defining-blades, all combined and operating together substantially as described.

7. The combination of a folding-bed, means for holding a bag-blank thereon; a defining-blade, mounted for vibration upon an axis substantially normal to the line of its defining edge, said axis forming an acute angle lengthwise with the folding-bed and means for folding the bag-blank down over the defining-blade, all combined and operating together substantially as described.

8. The combination of a folding-bed, means for holding a bag-blank thereon; a pair of defining-blades 38, 39 each vibrating upon an axis substantially normal to the line of its defining edge, said axes forming acute angles respectively with the folding-bed, means coacting with the folding-bed, for opening out the forward end of the bag-blank and folding the same down over the defining-blades all combined and operating together substantially as described.

9. The combination of a revoluble folding-bed, a pair of oppositely-disposed trunnions 58, 580 each mounted for oscillation about its own axes and about the axis of the folding-bed, side clips 23, 24 on the folding-bed, a pair of side nippers carried by each trunnion, said side nippers being mounted in their respective trunnions for vibration inwardly and outwardly with respect to the folding-bed, one of each pair of said side nippers being mounted for vibration toward and away from the other nipper of its respective pair, all combined and operating together substantially as described.

809,281. BONDING OR TYING DEVICE. WILLIAM B. THIMS, Trenton, N. J. Filed Aug. 29, 1904. Serial No. 222,619.



Claim.—1. In a bonding or tying device of the class set forth, the combination of two or more longitudinal strands arranged in parallel relation, and a single-strand cross-stay means alternately secured to the longitudinal strands at spaced intervals by a plurality of twists, the single-strand cross-stay having members bent in planes at right angles to and within the confines of the longitudinal strands, and the interlocking twists being formed both in the U-shaped bends of the cross-stay and in the longitudinal strands, the said single cross-stay having its parts in planes at right angles to the longitudinal strands and extending fully throughout the length of the bonding or tying device as a continuous structure.

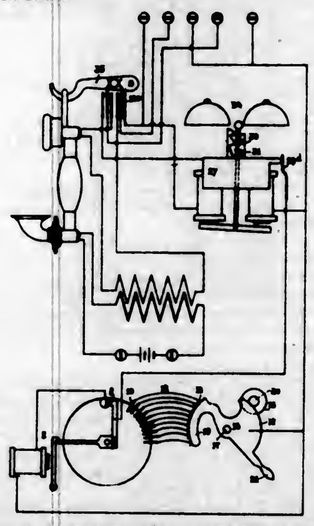
2. The combination with a wall, having courses of brick or stone therein, of a bonding or tying device therefor consisting of two or more longitudinal strands arranged in parallel relation, and a single-strand cross-stay having U-shaped members continuous with each other and alternately secured to the longitudinal strands by a plurality of twists, the said single-strand cross-stay having its parts in planes at right angles to the longitudinal strands and spaced regularly throughout the whole length of the tying device, the longitudinal strands and the cross-stay members being spaced such distances that the longitudinal strands disposed within the opposite side margins of the wall engage the intermediate portions of the courses and the single-strand cross-stay at regular intervals pass over the courses between the joints of the constituents thereof.

3. The combination with a wall, having courses of brick or stone included therein, of a bonding or tying means therefor consisting of longitudinal and transversely extending strands having U-shaped members continuous with each other and the bends disposed in reverse positions and engaging all the brick or stone, the transversely-extending strands being in planes at right angles to the longitudinal strands and spanning the longitudinal joints between the courses and also intersecting the transverse joints, and the longitudinal strands extending intermediately over the brick or stone elements and crossing the transverse joints thereof in planes at right angles.

4. The combination with a wall, having course of brick or stone, of a bond or tie having outer marginal longitudinally-extending strands, and an intermediate longitudinal strand parallel with the outer ones, and transversely-disposed strands having reversely-positioned U-shaped bends continuous with each other and alternately connected to the outer longitudinal strands and the intermediate longitudinal strands by twists and arranged in regular spaced parallel relation throughout the whole length of the bond or tie.

5. A bonding or tying device for the purpose set forth, having outer marginal longitudinally-extending strands, and an intermediate longitudinal strand parallel with the other ones, and a single-strand cross-stay having U-shaped members continuous with each other and alternately secured to the outer longitudinal strands and the inner or intermediate strands by a plurality of twists extending lengthwise of and formed both in the longitudinal strands and the bends of the said members and regularly spacing the cross-stay, the latter having its cross parts at planes at right angles to the longitudinal strands.

809,282. SEMI-AUTOMATIC TELEPHONE-EXCHANGE SYSTEM. ARTHUR T. M. TROTMAN, London, England. Filed Oct. 6, 1905. Serial No. 281,713.



Claim.—1. A telephone-exchange comprising a subscriber's latent-signal set including a signal-transmitter arranged to send its signal in groups, with a prolonged current change between the groups, a calling-board with subscriber's jacks and calling-plugs, a called board with subscriber's jacks and called plugs, a numerical indicator at the called board in the plug-circuit comprising a set of actuating-magnets, a commutator-relay to successively throw them into circuit, and a retarding-relay operated by the prolonged current changes to actuate the commutator-relay, these parts being set into operation by the plugging of the calling-plug into the calling-subscriber's jack, to indicate to the called operator the signal set substantially as described.

2. A telephone-exchange comprising a subscriber's latent-signal set, a calling-board with subscribers' jacks, a bench carrying calling-plugs and calling-plug switches, a called board with subscribers' jacks, a bench carrying called plugs, a supervisory lamp for the called plug in circuit with the calling-plug switches, and a numerical indicator at the called board in the plug-circuit, whereby the removal of the calling-plug from its plug-switch and the plugging of the calling-plug into the calling-subscriber's jack, lights the supervisory lamp at the called plug and actuates the numerical indicators to register the latent signal, substantially as described.

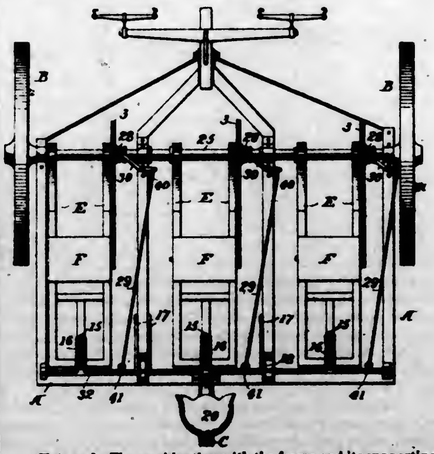
3. A telephone-exchange comprising a subscriber's latent-signal set including a signal-transmitter, arranged to send signals in groups with a prolonged current change between the groups, a calling-board with subscriber's jacks and calling-plugs, a called board with subscribers' jacks and called plugs, a numerical indicator, at the called board, in the plug-circuit, comprising a set of actuating-magnets and a circuit-changing restoring device, a commutator-relay to successively throw the magnets into circuit, and a retarding-relay operated by the prolonged current changes to actuate the commutator-relay, the parts being set into operation by the plugging of the calling-plug into the calling-subscriber's jack to indicate to the called operator the signal set, and the commutator-relay being returned to normal by the circuit-changer of the restoring device, substantially as described.

4. A telephone-exchange comprising a subscriber's latent-signal transmitter arranged to store a plurality of identical signals, two exchanges each comprising a calling-board with subscribers' jacks, trunking-jacks and calling-plugs, and a called board with subscribers' jacks, trunking-jacks, called plugs and a numerical indicator, in the plug-circuit, energized by the plugging of the calling-plug into the calling-subscriber's jack, whereby the first calling operator may register the stored signal on the first called board, the first called operator may trunk to the second exchange, and the second calling operator may again register the stored signal at the second called-operator's board, substantially as described.

5. A telephone-exchange comprising a subscriber's latent-signal set arranged to send its signals in separate groups, a calling-board with subscribers' jacks, a bench carrying calling-plugs, a called board with subscribers' jacks, a bench carrying called plugs, an electromagnetic distributer, and a numerical indicator comprising a set of indicators at the called board in the plug-circuit, energized by the plugging of a calling-plug into the calling subscriber's jack to simultaneously indicate to the called operator the several elements of the signal set on the subscribers' latent-signal transmitter, substantially as described.

6. A telephone-exchange comprising a subscriber's latent-signal set arranged to send its signal in separate groups, a calling-board withsubscribers' jacks and calling-plugs, a called board with subscribers' jacks, called-plug switches and called plugs therein, an electromagnetic distributer for distributing the several groups constituting a signal, and a numerical indicator, comprising a set of indicators, at the called board, in the plug-circuit passing through the called-plug switches, energized by plugging the calling-subscriber's plug into his jack, whereby the raising of the called plug from its called-plug switch cuts the numerical indicator out of circuit, substantially as described.

809,283. SUGAR-BEET SEEDER. FREDERICK TIEMANN, Ordway, Colo. Filed May 1, 1905. Serial No. 258,319.



Claim.—1. The combination with the frame and its supporting-wheels and shaft of a planter, of a plurality of supplemental frames each connected to said shaft to swing independently, each supporting plows and seed-distributing mechanism, means for operating said mechanisms from said shaft, and independent clutch devices between the shaft and each of said means, substantially as set forth.

2. The combination with the seedbox of a planter, having a port at the end, of a seed-wheel having pockets, means for rotating it to carry said pockets past said port, a closing-plate at the opposite side of the wheel having a port, and a conduit leading downward from the latter port, substantially as set forth.

3. The combination with the seedbox of a planter having an end piece and port therein, of a shaft extending through said end, a seed-wheel with pockets secured to said shaft and rotating in contact with

the outer face of said end piece, a plate in contact with the outer face of the wheel having a channel, the upper end of which is in position to coincide with the pockets, a plow, and a conduit extending from above the plow to the lower end of said channel, substantially as set forth.

4. In a seed-distributer, a box having a port at one end, a seed-wheel with pockets arranged to be brought opposite said port, a plate having a channel with which said pockets may be brought into communication, and a spring arranged adjacent said wheel to spring into each pocket as the latter passes the spring, substantially as set forth.

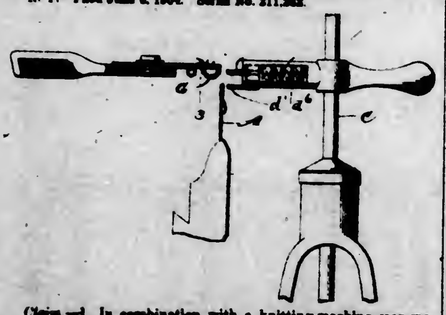
5. A box for a planter having an end piece with a port therein, a wheel with pockets rotating in contact with the outer face of said end piece, and a plate recessed at the inner face to receive said wheel and with a channel, the upper end of which is in position to coincide with the said pockets as the wheel revolves, substantially as set forth.

6. The combination with the frame of a planter, of a supplemental frame, a seedbox carried thereby, seed-distributing mechanism at each end of said box, and plows carried by said box, each plow on a bar adjustable vertically in said supplemental frame, substantially as set forth.

7. The combination with the main frame and driving-shaft, of the swinging seed-distributing frame, a rock-shaft, connections whereby to elevate the rear end of the seed-distributing frame, driving mechanism including a clutch device, and connections whereby the clutch device is shifted when the rock-shaft is operated to lift the seed-distributing frame, substantially as set forth.

8. The combination with the main frame, driving-shaft, swinging frame E, rock-shaft 32 connected to the frame E, and means for rocking said shaft, of sprocket-wheels loose upon the driving-shaft, sprocket-chains carried by said wheels and extending to pinions on the frames E, clutch devices for connecting the sprocket-wheels to and releasing them from the shaft, and connections whereby the clutch devices are shifted as the rock-shaft is turned, substantially as set forth.

809,284. **STOP-MOTION FOR KNITTING-MACHINES.** ERNEST TOMPKINS, Troy, N. Y., assignor to Tompkins Brothers Company, Troy, N. Y. Filed June 6, 1904. Serial No. 211,262.



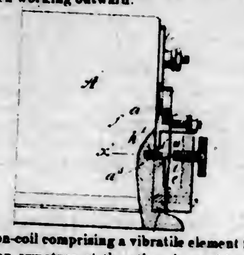
Claim.—1. In combination with a knitting-machine stop-motion having a stop-finger located outside the cloth and needles and having a cloth-presser located within the cloth; with a spring-controlled trip located within the cloth and needles adapted to engage the stop-finger and actuate the stop-motion when the cloth leaves the needles, said trip being controlled by the said presser, substantially as described.

2. In combination, a knitting-machine, and a stop-motion having a stop-finger located exterior to the needles and cloth, and a presser located within the needles and cloth; with a movable trip located adjacent to the presser and adapted to actuate the stop-finger when the cloth leaves the machine, substantially as described.

3. The combination of a knitting-machine, and a stop-motion having a spring-pressed stop-finger located exterior to the needles and cloth, and a spring-actuated presser located within the needles and cloth; with a laterally-movable trip located adjacent to the presser-arm, and connected therewith so as to be controlled thereby, said trip actuating the stop-finger when the cloth leaves the machine, substantially as described.

809,285. **INDUCTION-COIL VIBRATOR.** RICHARD VARLEY, Bridgeport, N. J., assignor to The Autocall Company, a Corporation of New Jersey. Filed Feb. 23, 1905. Serial No. 247,218.

Claim.—1. An induction-coil comprising a vibratile element fixed at one end and carrying an armature at the other, in combination with a tension-screw adapted to positively increase the tension of said element when working outward.



2. An induction-coil comprising a vibratile element fixed at one end and carrying an armature at the other, in combination with a tension-screw connected to said element to tension the same when moving outward.

3. An induction-coil comprising a vibratile element fixed at one end and carrying an armature at the other, in combination with a tension-screw having a left-hand thread and connected to positively engage the rear side of said element.

4. In a vibrator for induction-coils, the combination of a vibratile element, an adjusting-screw therefor and means for preventing excessively straining said element when the screw is worked in a direction to increase the tension thereof.

5. In a vibrator for induction-coils, the combination of a vibratile element, an adjusting-screw therefor and a stop limiting the outward movement of the screw.

6. In an induction-coil, a vibratory spring adapted to be drawn in one direction by the magnetic attraction of the coil, means for increasing the tension of the spring and means for preventing excessive increase of such tension.

7. In an induction-coil, a vibratory spring adapted to be drawn in one direction by the magnetic attraction of the coil, a screw for altering the tension of the spring and means for limiting the longitudinal movement of the screw.

8. In an induction-coil, a vibratory spring adapted to be drawn in one direction by the magnetic attraction of the coil, a screw adapted to give the spring an opposing tension and a stop on said screw limiting its ability to strain the spring.

9. A vibratile element for induction-coils comprising a flat spring having a notch in its fixed end and a screw passing through said notch and clamping the spring fast.

10. A vibratile element for induction-coils comprising a flat spring having a notch in its fixed end, a frame in two parts between which the fixed end of the spring is inserted and a screw passing through the two parts of the frame and the notch in the spring, for the purpose set forth.

11. The combination of the core of an induction-coil, a flat spring carrying an armature arranged in front of said core, said spring having at its fixed end two notches, and two clamping-screws passing through said notches and thereby positioning and clamping the spring.

12. In an induction-coil, a spring-plate, a screw passing transversely through the plate and independently mounted thereof and means whereby the plate is removable without removing the screw.

13. In an induction-coil, a spring-plate, a screw passing transversely through the plate and independently mounted thereof and adapted to regulate the tension of the spring and means whereby the plate is removable without removing the screw.

14. In an induction-coil, a spring-plate and an adjusting-screw mounted in front thereof and having an extension positively engaging its rear side.

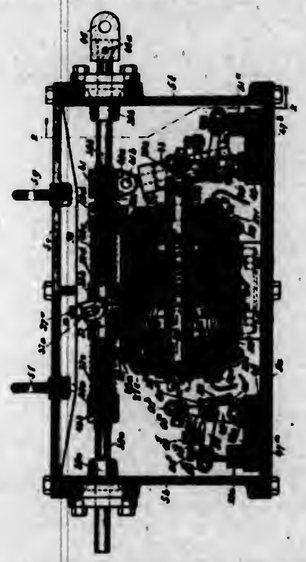
15. In an induction-coil, a spring-plate having an opening and an adjusting-screw passing through said opening and carrying a cross-head engaging the rear side of the plate.

16. In an induction-coil, a vibratory spring-plate having a notch and an adjusting-screw for said plate straddled by said notch.

17. In an induction-coil, a frame provided with two clamping-screws and an adjusting-screw, in combination with a spring-plate having three notches adapted to straddle the three screws respectively.

809,286. **ELECTROMAGNETIC SWITCH-SETTING APPARATUS AND ELECTRIC RAIL-HEATER.** BRUNO O. WAGNER, Swissvale, Pa. Filed Mar. 9, 1905. Serial No. 249,515.

Claim.—1. A switch-setting mechanism of the character stated, comprising a casing, a reciprocating electric motor mounted therein, a rod reciprocatably mounted in said casing and projecting outside thereof and adapted to be connected to the switch-point-connecting rod, a lever connection within the casing between the reciprocating motor and the reciprocating rod for imparting the motion of the motor to the rod, and circuit-closers mounted within the casing at each end of the motor and adapted to be operated by the reciprocating motor, substantially as shown and described.



2. In a switch-setting apparatus of the character stated, a casing, bearings detachably secured in the end walls therein, a rod reciprocatably mounted in said bearings and projecting outside of the casing, a coupling member on the end of said rod adapted to be connected with the switch-point-joining rod, a sleeve loosely held on the first-mentioned rod, buffer-springs at each side of said sleeve on said first-mentioned rod, a reciprocating electric motor mounted within the casing, a lever pivotally secured within the casing and connected with said sleeve on said first-mentioned rod and with the reciprocating armature of the motor whereby the motion of the motor is imparted to said first-mentioned rod, said motor including stationary field-magnets and a reciprocating armature-magnet, a shaft for said armature-magnet reciprocatably mounted in apertures in the field-magnets, and circuit-closers within the casing adapted to be engaged by said armature-shaft to operate the same as the shaft reaches the limit of its movement in each direction, substantially as shown and described.

3. A switch-setting mechanism of the character stated, comprising in combination with an electric motor consisting of a pair of stationary magnet-coils, cup-shaped iron pole-pieces for receiving said magnet-coils, a pulley-shaped armature having cavities in its ends, armature-coils held in said armature-cavities, said cup-shaped pole-pieces being centrally apertured, a shaft endwise movably held in said apertures of the pole-pieces, said armature being fixedly secured to said shaft to reciprocate between the pole-pieces, a rod mounted for endwise movement and a lever joining said rod with said armature for imparting the motion of the armature to the switch-rail-connecting rod, and circuit-closers mounted within the casing at each end of the motor and adapted to be operated by the reciprocating motor, substantially as shown and described.

4. A switch-setting mechanism of the character stated, in combination with an electric motor consisting of a pair of stationary magnet-coils, cup-shaped iron pole-pieces for receiving said magnet-coils, a pulley-shaped armature having cavities in its ends, armature-coils held in said armature-cavities, said cup-shaped pole-pieces being centrally apertured, a shaft endwise movably held in said apertures of the pole-pieces, said armature being fixedly secured to said shaft to reciprocate between the pole-pieces, and means for imparting the motion of the armature to switch-rail points substantially as shown and described.

5. A switch-setting mechanism of the character stated, comprising in combination with an electric motor consisting of a pair of stationary magnet-coils, cup-shaped iron pole-pieces for receiving said magnet-coils, a pulley-shaped armature having cavities in its ends, armature-coils held in said armature-cavities, said cup-shaped pole-pieces being centrally apertured, a shaft endwise movably held in said apertures of the pole-pieces, said armature being fixedly secured to said shaft to reciprocate between the pole-pieces, a rod mounted for endwise movement and a lever joining said rod with said armature to impart the armature motion to the rod, said rod having means for connecting with the switch-rail-connecting rod, circuit-closers mounted adjacent said pole-pieces and adapted to be engaged by the armature-shaft as it reaches the limit of its movement in each direction and toggle-spring devices for holding the parts in the position they assume when the armature is moved to the limit of its stroke in each direction, substantially as shown and described.

6. A switch-setting mechanism of the character stated, comprising the combination with an electric motor consisting of a pair of stationary magnet-coils, cup-shaped iron pole-pieces for receiving said magnet-coils, a pulley-shaped armature having cavities in its ends, armature-coils held in said armature-cavities, said cup-shaped pole-pieces being centrally apertured, a shaft endwise movably held in said apertures of the pole-pieces, said armature being fixedly secured to said shaft to reciprocate between the pole-pieces, a rod mounted for endwise movement and a lever joining said rod with said armature to impart the armature motion to the rod, said rod having means for connecting it with the switch-rail-connecting rod, of circuit-closers mounted adjacent said pole-pieces and adapted to be engaged by the armature-shaft as it reaches the limit of its movement in each direction, toggle devices for holding the parts in the position they assume when the armature has moved to the limit of its stroke in each direction, and a hermetically-closed housing for the whole, substantially as shown and described.

7. In a switch-setting apparatus, an electric motor comprising a pair of stationary field-magnets each consisting of a cup-shaped iron pole-piece and energizing-coils held within the cup portion of said pole-pieces, a cylindrical tubular casing secured to said pole-pieces and closed at the ends by said pole-pieces, said casing consisting of non-magnetic material, means for securing the energizing-coils of the field-magnets in position thereon, a pulley-shaped armature having cup portions at each end and mounted for reciprocation between the said pole-pieces within the casing, a shaft passing through apertures in the pole-pieces upon which said armature is fixedly secured, energizing-coils secured within the cup-shaped portion of the armature, means for holding said last-named coils in position, a reciprocating rod mounted adjacent to said motor, elastic connections between said rod and said motor-armature, whereby the motion of the armature is imparted to the rod, means for holding the rod and armature to their moved positions, and a hermetically-closed housing for the whole, substantially as shown and described.

8. In a switch-setting apparatus, an electric motor comprising a pair of stationary field-magnets each consisting of a cup-shaped iron pole-piece and energizing-coils held within the cup portion of said pole-pieces, a cylindrical tubular casing secured to said pole-pieces and closed at the ends by said pole-pieces, said casing consisting of non-magnetic material, means for securing the energizing-coils of the field-magnets in position thereon, a pulley-shaped armature having cup portions at each end and mounted for reciprocation between the said pole-pieces within the casing, a shaft passing through apertures in the pole-pieces upon which said armature is fixedly secured, energizing-coils held within the cup-shaped portion of the armature, means for holding said last-named coils in position, a reciprocating rod mounted adjacent to said motor, elastic connections between said rod and said motor-armature, whereby the motion of the armature is imparted to the rod, means for holding the rod and armature to their moved positions, a hermetically-closed housing for the whole, and circuit-closers mounted within said housing adjacent the ends of said motor and adapted to be engaged by the motor-shaft as it reaches the end of its stroke substantially as shown and described.

9. An apparatus of the character stated, comprising in combination with a pair of stationary field-magnets consisting of cup-shaped iron pole-pieces and energizing-coils held within the said pole-pieces, a housing of non-magnetic metal secured to and closed at the ends by said field-magnets, means for holding the coils of the field-magnets in position, said housing consisting of two semi-cylindrical parts embracing the pole-pieces to leave two longitudinal openings of equal widths extending the entire length of the housing and diametrically opposite to each other, said pole-pieces including centrally-apertured hubs to form bearings, a shaft longitudinally

slidable in said hub-bearings, insulating-pins in the ends of said shaft, a pulley-shaped iron armature fixedly secured to the middle portion of said shaft, said armature having coil-receiving portions at each end, energizing-coils mounted in said armature, means for holding said coils in position on the armature, said armature including a cylindrical rim having a pair of diametrically-disposed parallel grooves, a block of insulating material secured to the armature in one of said grooves and adapted to permit passage of the terminal wires of the armature-coils and to project through one of the openings between the housing portions, a metallic block secured to the armature in the other armature-groove, said block having a projecting stud and adapted to project through the other opening between the housing-sections, one of said sections being formed with a lug, a lever pivotally secured to said lug and having a bifurcated end to engage the stud of the metallic armature-block and a longitudinally-movable rod adapted to be engaged by the free end of said last-named lever for imparting motion to the switch-shifting rod, substantially as shown and described.

10. An apparatus of the character stated, comprising in combination with a pair of stationary field-magnets consisting of cup-shaped iron pole-pieces and energizing-coils held within the said pole-pieces, a housing of non-magnetic metal secured to and closed at the end by said field-magnets, means for holding the coils of the field-magnets in position said housing consisting of two semicylindrical parts embracing the pole-pieces to leave two longitudinal openings of equal widths extending the entire length of the housing and diametrically opposite to each other, said pole-pieces including centrally-apertured hubs to form bearings, a shaft longitudinally slidable in said hub-bearings, insulating-pins in the ends of said shaft, a pulley-shaped iron armature fixedly secured to the middle portion of said shaft, said armature having coil-receiving portions at each end, energizing-coils mounted in said armature, means for holding said coils in position on the armature, said armature including a cylindrical rim having a pair of diametrically-disposed parallel grooves, a block of insulating material secured to the armature in one of said grooves and adapted to permit passage of the terminal wires of the armature-coils and to project through one of the openings between the housing portions, a metallic block secured to the armature in the other armature-groove, said block having a projecting stud and adapted to project through the other opening between the housing-sections, one of said housing-sections being formed with a lug, a lever pivotally secured to said lug and having a bifurcated end to engage the stud of the metallic armature-block and a longitudinally-movable rod adapted to be engaged by the free end of said last-named lever for imparting motion to the switch, and a pair of circuit-closers each adapted to be engaged by the armature-shaft as it reaches the limit of its stroke substantially as shown and described.

11. An apparatus of the character stated, comprising in combination with a pair of stationary field-magnets consisting of cup-shaped iron pole-pieces and energizing-coils held within the said pole-pieces, a housing of non-magnetic metal secured to and closed at the ends by said field-magnets, means for holding the coils of the field-magnets in position, said housing consisting of two semicylindrical parts embracing the pole-pieces to leave two longitudinal openings of equal widths extending the entire length of the housing and diametrically opposite to each other, said pole-pieces including centrally-apertured hubs to form bearings, a shaft longitudinally slidable in said hub-bearings, insulating-pins in the ends of said shaft, a pulley-shaped iron armature fixedly secured to the middle portion of said shaft, said armature having coil-receiving portions at each end, energizing-coils mounted in said armature, means for holding said coils in position on the armature, said armature including a cylindrical rim having a pair of diametrically-disposed parallel grooves, a block of insulating material secured to the armature in one of said grooves and adapted to permit passage of the terminal wires of the armature-coils and to project through one of the openings between the housing portions, a metallic block secured to the armature in the other armature-groove, said block having a projecting stud adapted to project through the other opening between the housing-sections, one of said housing-sections being formed with a lug, a lever pivotally secured to said lug and having a bifurcated end to engage the stud of the metallic armature-block and a longitudinally-movable rod adapted to be engaged by the free end of said last-named lever for imparting motion to the switch-shifting rod, and a pair of circuit-closers each adapted to be engaged by the armature-shaft as it reaches the limit of its stroke, and toggle-spring devices for securing the parts in their extreme positions, substantially as shown and described.

12. An apparatus of the character stated, comprising in combination with a pair of stationary field-magnets consisting of cup-shaped iron pole-pieces and energizing-coils held within the said pole-pieces, a housing of non-magnetic metal secured to and closed at the ends by said field-magnets, means for holding the coils of the field-magnets in position, said housing consisting of two semicylindrical parts embracing the pole-pieces to leave two longitudinal openings of equal widths extending the entire length of the housing and diametrically opposite to each other, said pole-pieces including centrally-apertured hubs to form bearings, a shaft longitudinally slidable in said hub-bearings, insulating-pins in the ends of said shaft, a pulley-shaped iron armature fixedly secured to the middle portion of said shaft, said armature having coil-receiving portions at each end, energizing-coils mounted in said armature, means for holding said coils in position on the armature, said armature including a cylindrical rim having a pair of diametrically-disposed parallel grooves, a block of insulating material secured to the armature in one of said grooves and adapted to permit passage of the terminal wires of the armature-coils and to project through one of the openings between the housing portions, a metallic block secured to the armature in the other armature-groove, said block having a projecting stud adapted to project through the other opening between the housing-sections, one of said sections being made with a lug, a lever pivotally secured to said lug and having a bifurcated end to engage the stud of the metallic armature-block, a longitudinally-movable rod adapted to be engaged by the free end of said last-named lever for imparting motion to the switch-shifting rod, a pair of circuit-closers each adapted to be engaged by the armature-shaft as it reaches the limit of its stroke, toggle-spring devices for securing the parts in their extreme positions, and a hermetically-sealed housing for the whole.

13. An apparatus of the character stated comprising an electric motor consisting of a pair of stationary field-magnets, each comprising a cup-shaped iron pole-piece, energizing-coils held within said cup-shaped pole-pieces, a pulley-shaped armature having cup-shaped ends, energizing-coils held within said cup-shaped ends of the armature, an armature-shaft fixedly secured to the armature and reciprocatably mounted in bearing-apertures in the cup-shaped pole-pieces, said armature being adapted for reciprocatable motion between said cup-shaped pole-pieces, a switch-shifting rod, bearings for said rod, said switch-shifting rod being mounted parallel with the armature-shaft and adapted to be connected with the rail-switch-connecting bar, a metallic sleeve slidable upon said shifting rod, adjusting-nuts at each side of said metallic sleeve on said rod, coil-springs mounted on the rod between the sleeve and the adjusting-nuts, a pivotally-mounted lever having one end in connection with the armature and the other end in connection with the sleeve, and a toggle-spring attachment secured to said switch-shifting rod at one end, and fixedly held at its other end to lock the parts to their shifted positions, substantially as shown and described.

14. An apparatus of the character stated, comprising an electric motor consisting of a pair of stationary field-magnets, each comprising a cup-shaped iron pole-piece, energizing-coils held within said cup-shaped pole-pieces, a pulley-shaped armature having cup-shaped ends, energizing-coils held within said cup-shaped ends of the armature, an armature-shaft fixedly secured to the armature and reciprocably mounted in bearing-apertures in the cup-shaped pieces, said armature being adapted for reciprocatable motion between said cup-shaped pole-pieces, a switch-shifting rod, bearings for said rod, said switch-shifting rod being mounted parallel with the armature-shaft and adapted to be connected with the rail-switch-connecting bar, a metallic sleeve slidable upon said shifting rod, adjustable nuts at each side of said metallic sleeve on said rod, coil-springs mounted on the rod between the sleeve and the adjusting-nuts, a pivotally-mounted lever having one end in connection with the armature and the other end in connection with the sleeve, a toggle-spring attachment comprising a swing-bracket mounted for oscillatory movement, an eyebolt longitudinally mounted in said bracket, a collar fixedly secured to said eyebolt between the bearing portions of the bracket, a coil-spring on said eyebolt between said collar and one of said bracket-bearing portions, a clevis secured to the switch-shifting rod, said eyebolt being pivotally connected with said clevis, said toggle attachment being arranged to hold the parts in their shifted positions, substantially as shown and described.

15. An apparatus of the character stated, comprising an electric motor consisting of a pair of stationary field-magnets, each comprising a cup-shaped iron pole-piece, energizing-coils held within said cup-shaped pole-pieces, a pulley-shaped armature having cup-shaped ends, energizing-coils held within said cup-shaped ends of the armature, an armature-shaft fixedly secured to the armature and reciprocably mounted in bearing-apertures in the cup-shaped pieces, said armature being adapted for reciprocatable motion between said cup-shaped pole-pieces, a switch-shifting rod, bearings for said rod, said switch-shifting rod being mounted parallel with the armature-shaft and adapted to be connected with the rail-switch-connecting bar, a metallic sleeve slidable upon said shifting rod, adjustable nuts at each side of said metallic sleeve on said rod, coil-springs mounted on the rod between the sleeve and the adjusting-nuts, a pivotally-mounted lever having one end in connection with the armature and the other end in connection with the sleeve, a toggle-spring attachment comprising a swing-bracket mounted for oscillatory movement, an eyebolt longitudinally mounted in said bracket, a collar fixedly secured to said eyebolt between the bearing portions of the bracket, a coil-spring on said eyebolt between said collar and one of said bracket-bearing portions, a clevis secured to the switch-shifting rod, said eyebolt being pivotally connected with said clevis, said toggle-spring attachment being arranged to hold the parts in their shifted positions, a metallic cup being secured to said insulated base and out of contact with said pillar to coöperate with said last-named set-screw, said metallic cup adapted to contain mercury and to be engaged by said last-named set-screw when the circuit-closer has been operated upon by the armature-shaft, and a hermetically-sealed housing for the whole.

16. An apparatus of the character stated, comprising an electric motor consisting of field and armature magnets, said field-magnets each including a cup-shaped iron pole-piece, said armature consisting of a pulley-shaped body having oppositely-arranged cavities, energizing-coils held in said armature-cavities, energizing-coils held in the cup-shaped pole-pieces, a shaft to which said armature is fixedly secured and which projects through bearing-apertures in the pole-pieces to allow the armature to describe a longitudinal motion between the pole-pieces, a switch-shifting rod, lever connections between the switch-shifting rod and the armature to impart the motion of the armature to the switch-shifting rod, toggle-spring devices for locking the entire mechanism to its final positions, circuit-closers mounted adjacent the motor for operation by said motor-armature, an iron housing for hermetically and water-proofingly inclosing the entire electromechanical apparatus, said housing serving also as a junction-box for all cable-joints, and comprising a metallic frame having a pair of oppositely-disposed outwardly-projected apertured bosses, metallic bearing-bushings secured to the said housing and projecting within said bosses, said bearings adapted to receive the switch-shifting rod, said housing having an inside flat portion, a terminal block having binding-screws, mounted on said flat portion within the housing, said toggle devices being secured at one end to said housing, means carried by the housing for hermetically passing the leading-in cables through the housing-wall, a metallic bottom plate secured to the bottom of said housing-frame and a removable cover-plate secured to the top of said housing-frame, said cover-plate having a plurality of finger-engaging eyebolts for the purposes specified.

17. In a switch-setting mechanism of the character stated, an electric motor comprising stationary field-magnets each consisting of a cup-shaped iron pole-piece, energizing-coils held within the cup-shaped pole-pieces, a pulley-shaped armature having cup-shaped coil-receiving portions at each end, energizing-coils held in said cup-shaped portions of the armature, an armature-shaft endwise movable in bearing-apertures in the cup-shaped field-magnet pole-pieces and fixedly secured to the armature, said armature being adapted for reciprocatable motion between the pole-pieces of the field-magnets, a switch-shifting rod, connections between said switch-shifting rod and said motor-armature for imparting the motion of the motor-armature to the switch-shifting rod, circuit-closers mounted adjacent each end of the motor and adapted to be operated by the armature-shaft as it reaches the limit of its stroke in either direction, each circuit-closer consisting of a base of insulating material, a metallic pillar having a horizontal arm or jib at its top and being mounted on said insulating-base, wire-receiving terminal screws at the foot of said pillar, a pin secured to the foot portion of said pillar, an adjustable set-screw in the outer end of said jib, an angular lever fulcrumed upon said pillar and provided with a pin on its operating-arm, a coil-spring connecting said first-named pin to said second-named pin said armature-shaft having insulating members in its ends, an adjustable set-screw in the end piece of the operating-arm of said angle-levers of the circuit-closers for operating with said insulating armature-shaft members, means for securing said set-screw to its adjusted position, a metallic set-screw at the other end of the angle-lever, means for mechanically securing said last-named set-screw to its adjusted positions, a metallic cup being secured to said insulated base and out of contact with said pillar to coöperate with said last-named set-screw, said metallic cup adapted to contain mercury and to be mechanically engaged by said last-named set-screw when the circuit-closer has been operated upon by the armature-shaft, substantially as shown and described.

18. An apparatus of the character stated, comprising an electric motor consisting of field and armature magnets, said field-magnets each including a cup-shaped iron pole-piece, said armature consisting of a pulley-shaped body having oppositely-arranged cavities, energizing-coils held in said armature-cavities, energizing-coils held in the cup-shaped pole-pieces, a shaft to which said armature is fixedly secured and which projects through bearing-apertures in the pole-pieces to allow the armature to describe a longitudinal motion between the pole-pieces, a switch-shifting rod, lever connections between the switch-shifting rod and the armature to impart the motion of the armature to the switch-shifting rod, toggle-spring devices for locking the entire mechanism to its final positions, circuit-closers mounted adjacent the motor for operation by said motor-armature, an iron housing for hermetically and water-proofingly inclosing the entire electromechanical apparatus, said housing serving also as a junction-box for all cable-joints, and comprising a metallic frame having a pair of oppositely-disposed outwardly-projected apertured bosses, metallic bearing-bushings secured to the said housing and projecting within said bosses, said bearings adapted to receive the switch-shifting rod, said housing having an inside flat portion, a terminal block having binding-screws, mounted on said flat portion within the housing, said toggle devices being secured at one end to said housing, means carried by the housing for hermetically passing the leading-in cables through the housing-wall, a metallic bottom plate secured to the bottom of said housing-frame and a removable cover-plate secured to the top of said housing-frame, said cover-plate having a plurality of finger-engaging eyebolts for the purposes specified.

19. In a switch-setting apparatus, an electric motor comprising a pair of stationary field-magnets each consisting of a cup-shaped iron pole-piece and energizing-coils held within the cup portion of said pole-pieces, a cylindrical tubular casing secured to said pole-pieces and closed at the ends by said pole-pieces, said casing consisting of non-magnetic material, means for securing the energizing-coils of the field-magnets in position thereon, a pulley-shaped armature having cup portions at each end and mounted for reciprocation between the said pole-pieces within the casing, a shaft passing through apertures in the pole-pieces upon which said armature is fixedly secured, energizing-coils secured within the cup-shaped portion of the armature, means for holding said last-named coils in position.

20. In a system of the character stated, a source of electric energy, an electromagnetic switch-setting mechanism including field and armature coils in circuit with the source of electric energy, a reversing-switch for reversing the current in the armature, a balanced electromagnetic indicator in the armature-circuit, and means controlled by the switch-setting mechanism for varying the electric current as it passes through the indicator to upset its balance to indicate the position of the switch.

21. In a system of the character stated, a source of electric energy, an electromagnetic switch-setting mechanism including field and armature electromagnets, in circuit with the source of electric energy, a current-reversing switch in the armature-circuit, a balanced electromagnetic indicator in the armature-circuit, and means controlled by the switch-setting mechanism for varying the electric current in a portion of the armature-circuit as it passes through the indicator to upset the indicator-balance to cause the indicator to indicate the position of the switch.

22. In a system of the character stated, a source of electric energy, an electromagnetic switch-setting mechanism including field and armature electromagnets, a pair of line-wires connecting the field-magnet coils with the source of electric energy, a second pair of line-wires connecting the armature-coils with the source of electric energy, current-reversing switch in the armature-circuit, a balanced indicator including a pair of coils, one of which is connected in series with one armature line-wire and the other connected in series with the other armature line-wire, and means controlled by the switch-setting mechanism, for varying the current in one of said armature line-wires to upset the balance of the indicator to cause it to indicate the position of the switch-setting mechanism.

23. In a system of the character stated, a source of electric energy, an electromagnetic switch-setting mechanism including field and armature electromagnets, a pair of line-wires connecting the

field-magnet coils with the source of energy, a second pair of line-wires connecting the armature-coils with the source of energy, a current-reversing switch in the armature-circuit, a balanced indicator including a pair of operating-coils, one of which is connected in series with one armature line-wire and the other connected in series with the other line-wire, and means controlled by the switch-setting mechanism for shunting a supplemental current through one of said armature line-wires to upset the balance of the indicator.

24. In a system of the character stated, a source of electric energy, an electromagnetic switch-setting mechanism including field and armature electromagnets, a pair of line-wires connecting the field-magnet coils with the source of electric energy, a second pair of line-wires connecting the armature-coils with the source of electric energy, a current-reversing switch in the armature-circuit, a balanced indicator including a pair of coils, one of which is connected in series with one armature line-wire and the other connected in series with the other armature line-wire, and means controlled by the switch-setting mechanism, for varying the current in one of said armature line-wires to upset the balance of the indicator to cause it to indicate the position of the switch-setting mechanism, without changing the flow of current through the armature.

25. In a system of the character stated, a source of electric energy, an electromagnetic switch-setting mechanism including field and armature electromagnets, a pair of line-wires connecting the field-magnet coils with the source of energy, a second pair of line-wires connecting the armature-coils with the source of energy, a current-reversing switch in the armature-circuit, a balanced indicator including a pair of operating-coils one of which is connected in series with one armature line-wire and the other connected in series with the other line-wire, and means controlled by the switch-setting mechanism for shunting a supplemental current through one of said armature line-wires to upset the balance of the indicator, without changing the flow of current through the armature.

26. In a system of the character stated, a source of electric energy, an electromagnetic switch-setting mechanism including field and armature electromagnets, a pair of line-wires connecting the field-magnet coils with the source of electric energy, a second pair of line-wires connecting the armature-coils with the source of electric energy, a current-reversing switch in the armature-circuit, a balanced indicator including a pair of coils, one of which is connected in series with one armature line-wire and the other connected in series with the other armature line-wire, and means controlled by the switch-setting mechanism, for varying the current in one of said armature line-wires to upset the balance of the indicator to cause it to indicate the position of the switch-setting mechanism, said last-named means comprising a circuit-closer connected to one armature line-wire and to the field-coil circuit midway between the field-coils.

27. In a system of the character stated, a source of electric energy, an electromagnetic switch-setting mechanism including field and armature electromagnets, a pair of line-wires connecting the field-magnet coils with the source of electric energy, a second pair of line-wires connecting the armature-coils with the source of electric energy, a current-reversing switch in the armature-circuit, a balanced indicator including a pair of coils, one of which is connected in series with one armature line-wire and the other connected in series with the other armature line-wire, and means controlled by the switch-setting mechanism, for varying the current in one of said armature line-wires to upset the balance of the indicator to cause it to indicate the position of the switch-setting mechanism, said last-named means comprising a circuit-closer connected to one armature line-wire and to the field-coil circuit midway between the field-coils, and a second circuit-closer likewise connected to the field-coil circuit and to the other armature line-wire.

28. In a system of the character stated, a source of electric energy, an electromagnetic switch-setting mechanism including field and armature electromagnets, a pair of line-wires connecting the field-magnet coils with the source of electric energy, a second pair of line-wires connecting the armature-coils with the source of electric energy, a current-reversing switch in the armature-circuit, a balanced indicator including a pair of coils, one of which is connected in series with one armature line-wire and the other connected in series with the other line-wire, and means controlled by the switch-setting mechanism for varying the current in one of said armature line-wires to upset the balance of the indicator to cause it to indicate the position of the switch-setting mechanism, said last-named means comprising a circuit-closer connected to one armature line-wire and to the field-coil circuit midway between the field-coils, and a second circuit-closer likewise connected to the field-coil circuit and to the other armature line-wire, said circuit-closers each including portions to be engaged by the armature to operate the closers.

29. In a system of the character stated, a source of electric energy, an electromagnetic switch-setting mechanism including field and armature electromagnets, a pair of line-wires connecting the field-magnet coils with the source of energy, a second pair of line-wires connecting the armature-coils with the source of energy, a current-reversing switch in the armature-circuit, a balanced indicator including a pair of operating-coils, one of which is connected in series with one armature line-wire and the other connected in series with the other armature line-wire, and means controlled by the switch-setting mechanism for shunting a supplemental current through one of said armature line-wires to upset the balance of the indicator, said means comprising a circuit-closer connected to one armature line-wire and to the field-coil circuit midway between the field-coils.

30. In a system of the character stated, a source of electric energy, an electromagnetic switch-setting mechanism including field and armature electromagnets, a pair of line-wires connecting the field-magnet coils with the source of energy, a second pair of line-wires connecting the armature-coils with the source of energy, a current-reversing switch in the armature-circuit, a balanced indicator including a pair of operating-coils, one of which is connected in series with one armature line-wire and the other connected in series with the other armature line-wire, and means controlled by the switch-setting mechanism for shunting a supplemental current through one of said armature line-wires to upset the balance of the indicator, said means comprising a circuit-closer connected to one armature line-wire and to the field-coil circuit midway between the field-coils, and a second circuit-closer likewise connected to the field-coil circuit and to the other armature line-wire, said circuit-closers each including portions to be engaged by the armature to operate the closers.

31. In a system of the character stated, a source of electric energy, an electromagnetic switch-setting mechanism including field and armature electromagnets, a pair of line-wires connecting the field-magnet coils with the source of energy, a second pair of line-wires connecting the armature-coils with the source of energy, a current-reversing switch in the armature-circuit, a balanced indicator including a pair of operating-coils one of which is connected in series with one armature line-wire and the other connected in series with the other line-wire, and means controlled by the switch-setting mechanism for shunting a supplemental current through one of said armature line-wires to upset the balance of the indicator, without changing the flow of current through the armature, said last-named means comprising circuit-closers connected to the field-coil circuit between the field-coils and to the armature line-wires, and including portions for engaging with the armature and to be operated thereby.

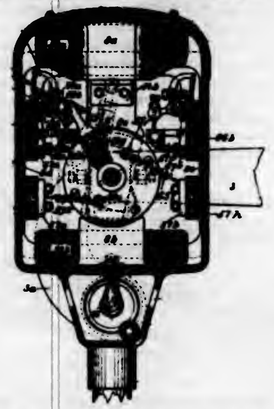
32. In a system of the character stated, a source of electric energy, an electromagnetic switch-setting mechanism including field and armature coils in circuit with the source of electric energy, a reversing-switch for reversing the current in the armature, a balanced electromagnetic indicator in the armature-circuit, and means controlled by the switch-setting mechanism for varying the electric current as it passes through the indicator to upset the balance to indicate the position of the switch, and electric heaters adapted to be disposed adjacent the switch-rails and connected in series with the switch-setting mechanism.

33. In a system of the character stated, a source of electric energy, an electromagnetic switch-setting mechanism including field and armature electromagnets, in circuit with the source of electric energy, a current-reversing switch in the armature-circuit, a balanced electromagnetic indicator in the armature-circuit, means controlled by the switch-setting mechanism for varying the electric current in a portion of the armature-circuit as it passes through the indicator to upset the indicator-balance to cause the indicator to indicate the position of the switch, and electric heaters adapted to be disposed adjacent the switch-rails and connected in series with the switch-setting mechanism.

34. In a system of the character stated, a source of electric energy, an electromagnetic switch-setting mechanism including field and armature electromagnets, a pair of line-wires connecting the field-magnet coils with the source of energy, a second pair of line-wires connecting the armature-coils with the source of energy, a current-reversing switch in one armature-circuit, a balanced indicator including a pair of operating-coils, one of which is connected in series with one armature line-wire and the other connected in series with the other line-wire, means controlled by the switch-setting mechanism for shunting a supplemental current through one of said armature line-wires to upset the balance of the indicator, and electric heaters adapted to be disposed adjacent the switch-rails and connected in series with the switch-setting mechanism.

35. In a system of the character stated, a source of electric energy, an electromagnetic switch-setting mechanism including field and armature electromagnets, a pair of line-wires connecting the field-magnet coils with the source of electric energy, a second pair of line-wires connecting the armature-coils with the source of electric energy, a current-reversing switch in the armature-circuit, a balanced indicator including a pair of coils, one of which is connected in series with one armature line-wire and the other connected in series with the other armature line-wire, and means controlled by the switch-setting mechanism for varying the current in one of said armature line-wires to upset the balance of the indicator to cause it to indicate the position of the switch-setting mechanism without changing the flow of current though the armature, and electric heaters adapted to be disposed adjacent the switch-rails and connected in series with the switch-setting mechanism.

809,237. SEMAPHORE MECHANISM. BRUNO O. WAGNER, Swissvale, Pa. Filed Mar. 9, 1905. Serial No. 249,316.



Claim.—1. In a mechanism of the character stated, a housing of magnetic material, pole-pieces integrally formed within said housing, energizing-coils carried by said pole-pieces, an armature mounted for limited rotatable movement between the pole-pieces, circuit-closers within the housing, means carried by the armature for operating the circuit-closers at times, a semaphore-blade on the outside of the housing coöperatively connected to turn with the armature, said blade having a tailpiece provided with a colored glass, a supplemental housing formed with and below the first-mentioned housing, said supplemental housing adapted to receive an incandescent lamp and a resistance-coil, said supplemental housing having apertures diagonally opposite each other, one of which is adapted to register with the tailpiece-glass when the semaphore is in one position, and terminal blocks for making wire connections mounted within the housing.

2. In a mechanism of the character stated, a housing of magnetic material, pole-pieces integrally formed within said housing energizing-coils carried by said pole-pieces, an armature mounted for limited rotatable movement between the pole-pieces, circuit-closers within the housing, means carried by the armature for operating the circuit-closers at times, a semaphore-blade on the outside of the housing coöperatively connected to turn with the armature, said blade having a tailpiece provided with a colored glass, a supplemental housing formed with and below the first-mentioned housing, said supplemental housing adapted to receive an incandescent lamp and a resistance-coil, said supplemental housing having apertures diagonally opposite each other, one of which is adapted to register with the tailpiece-glass when the semaphore is in one position, terminal blocks for making wire connections mounted within the housing, and a supplemental roof for the housing.

3. In a semaphore mechanism, a housing formed of magnetic material, pole-pieces integrally formed within said housing, one of said pole-pieces being longer than the other, energizing-coils carried by said pole-pieces, an armature mounted for limited rotary movement between said pole-pieces, said housing having openings at its ends, closure-caps for said openings, said closure-caps being provided with bearings, said armature having shaft portions extending through said closure-cap bearings, a semaphore-blade secured to one of said shaft portions, circuit-closers within the housing, means carried by the armature for operating the circuit-closers, and toggle-spring devices for holding the armature to its moved positions.

4. In a semaphore mechanism, a housing formed of magnetic material, pole-pieces integrally formed within said housing, one of said pole-pieces being longer than the other, energizing-coils carried by said pole-pieces, an armature mounted for limited rotary movement between said pole-pieces, said housing having openings at its ends, closure-caps for said openings, said closure-caps being provided with bearings, said armature having shaft portions extending through said closure-cap bearings, a semaphore-blade secured to one of said shaft portions, circuit-closers within the housing, means carried by the armature for operating the circuit-closers, toggle-spring devices for holding the armature to its moved positions, said housing having a supplemental chamber at its under side and being provided with a collar portion by means of which it may be secured to a pole, an incandescent lamp and a resistance-coil in said supplemental chamber, said supplemental chamber having ventilating-apertures, said supplemental chamber having a pair of alining apertures in opposite walls, transparent covers for said alining apertures, said semaphore having a tailpiece carrying a colored glass for registering with one of said alining apertures, a resilient buffer-spring device for said armature substantially as shown and described.

5. In an apparatus of the character stated, a housing of magnetic metal, a pair of pole-pieces integrally formed therewith within the housing, one of said pole-pieces being of greater length than the other, an energizing-coil mounted on said longer pole-piece, means for holding said coil in place on said longer pole-piece, an energizing-coil for the other pole-piece, said housing having openings in its end walls, closure-plates having bearings and integrally-formed drip-pans, an armature, a disk secured to each end of the armature, short shafts secured to each disk and passing through the bearings in the closure-plates, an arm carried by one of said shafts, a bracket pivotally connected to said arm, an eyebolt carried by said bracket, said eyebolt being pivotally secured to the longer pole-piece, a collar and a coil-spring on said eyebolt for forcing the eyebolt in one direction, one of said armature-shafts projecting through its closure-plate, and a semaphore-blade mounted on said last-named shaft-section.

6. In an apparatus of the character stated, a housing of magnetic metal, a pair of pole-pieces integrally formed therewith within the housing, one of said pole-pieces being of greater length than the other, an energizing-coil mounted on said longer pole-piece, means for holding said coil in place on said longer pole-piece, an energizing-coil for the other pole-piece, said housing having openings in its end walls, closure-plates for said openings, said closure-plates having bearings and integrally-formed drip-pans, an armature, a disk secured to each end of the armature, short shafts, secured to each disk and passing through the bearings in the closure-plates, an arm carried by one of said shafts, a bracket pivotally connected to said arm, an eyebolt carried by said bracket, said eyebolt being pivotally secured to the longer pole-piece, a collar and a coil-spring on said eyebolt for forcing the eyebolt in one direction, one of said armature-shafts projecting through its closure-plate, a semaphore-blade mounted on said last-named shaft-sections, means mounted within the casing and adapted to be engaged by said shaft-arm as the armature has reached the limit of its movement in each direction to serve as a buffer-spring therefor, circuit-closers mounted within the casing, an arm secured to one of said armature-disks for operating the circuit-closers.

7. In an apparatus of the character stated, a housing of magnetic metal, a pair of pole-pieces integrally formed therewith within the housing, one of said pole-pieces being of greater length than the other, an energizing-coil mounted on said longer pole-piece, means for holding said coil in place on said longer pole-piece, an energizing-coil for the other pole-piece, said housing having openings in its end walls, closure-plates for said openings, said closure-plates having bearings and integrally-formed drip-pans, an armature, a disk secured to each end of the armature, short shafts secured to each disk and passing through the bearings in each closure-plate, an arm carried by one of said shafts, a bracket pivotally connected to said arm, an eyebolt carried by said bracket, said eyebolt being pivotally secured to the longer pole-piece, a collar and a coil-spring on said eyebolt for forcing the eyebolt in one direction, one of said armature-shafts projecting through its closure-plate, a semaphore-blade mounted on said last-named shaft-section, means mounted within the casing and adapted to be engaged by said shaft-arm as the armature has reached the limit of its movement in each direction to serve as a buf-

for therefor, circuit-closers mounted within the casing, an arm secured to one of said armature-disks for operating the circuit-closers, each of said circuit-closers comprising a fixedly-held mercury-cup and a pivotally-mounted arm, an adjustable contact-point carried by each arm, a coil-spring for normally holding the arm with its contact-point out of the mercury-cup and an insulating-base upon which said arm and said mercury-cup are secured.

8. In an apparatus of the character stated, a housing of magnetic metal, a pair of pole-pieces integrally formed therewith within the housing, one of said pole-pieces being of greater length than the other, an energizing-coil mounted on said longer pole-piece, means for holding said coil in place on said longer pole-piece, an energizing-coil for the other pole-piece, said housing having openings in its end walls, closure-plates for said openings, said closure-plates having bearings and integrally-formed drip-pans, an armature, a disk secured to each end of the armature, short shafts secured to each disk and passing through the bearings in the closure-plates, an arm carried by one of said shafts, a bracket pivotally connected to said arm, an eyebolt carried by said bracket, said eyebolt being pivotally secured to the longer pole-piece, a collar and a coil-spring on said eyebolt for forcing the eyebolt in one direction, one of said armature-shafts projecting through its closure-plate, a semaphore-arm mounted on said last-named shaft-section, means mounted within the casing and adapted to be engaged by said shaft-arm as the armature has reached the limit of its movement in each direction to serve as a buffer therefor, circuit-closers mounted within the casing, an arm secured to one of said armature-disks for operating the circuit-closers, each of said circuit-closers comprising a fixedly-held mercury-cup and a pivotally-mounted arm, an adjustable contact-point carried by each arm, a coil-spring for normally holding the arm with its contact-point out of the mercury-cup and an insulating-base upon which said arm and said mercury-cup are secured, a supplemental roof for said housing and means for securing said housing to a pole.

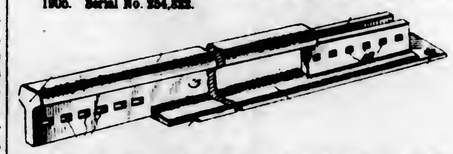
9. In an apparatus of the character stated, a housing of magnetic metal, a pair of pole-pieces integrally formed therewith within the housing, one of said pole-pieces being of greater length than the other, an energizing-coil mounted on said longer pole-piece, means for holding said coil in place on said longer pole-piece, an energizing-coil for the other pole-piece, said housing having openings in its end walls, closure-plates having bearings and integrally-formed drip-pans, an armature, a disk secured to each end of the armature, short shafts secured to each disk and passing through the bearings in the closure-plates, an arm carried by one of said shafts, a bracket pivotally connected to said arm, an eyebolt carried by said bracket, said eyebolt being pivotally connected to the longer pole-piece, a collar and a coil-spring on said longer pole for forcing the eyebolt in one direction, one of said armature-shafts projecting through its closure-plate, a semaphore-blade mounted on said last-named shaft-section, means mounted within the casing and adapted to be engaged by said shaft-arm as the armature has reached the limit of its movement in each direction to serve as a buffer therefor, circuit-closers mounted within the casing, an arm secured to one of said armature-disks for operating the circuit-closers, each of said circuit-closers comprising a fixedly-held mercury-cup and a pivotally-mounted arm, an adjustable contact-point carried by each arm, a coil-spring for normally holding the arm with its contact-point out of the mercury-cup and an insulating-base upon which said arm and said mercury-cup are secured, a supplemental roof for said housing and means for securing said housing to a pole, said housing including an extension forming a supplemental chamber, an electric light mounted in said supplemental chamber, said supplemental chamber having apertures in its end walls, tubular members held in said apertures, transparent closure members for the outer ends of said tubular members, said semaphore-blade having a tailpiece, a colored transparent disk carried by said tailpiece for registering with said transparent closer members of one of said tubular members.

10. In an apparatus of the character stated, a housing of magnetic metal, a pair of pole-pieces integrally formed therewith within the housing, one of said pole-pieces being of greater length than the other, an energizing-coil mounted on said longer pole-piece, means for holding said coil in place on said longer pole-piece, an energizing-coil for the other pole-piece, said housing having openings in its end walls, closure-plates for said openings, said closure-plates having bearings and integrally-formed drip-pans, an armature, a disk secured to each end of the armature, short shafts secured to each disk and passing through the bearings in the closure-plates, an arm carried by one of said shafts, a bracket pivotally connected to said arm, an eyebolt carried by said bracket, said eyebolt being pivotally secured to the longer pole-piece, a collar and a coil-spring on said eyebolt, for forcing the eyebolt in one direction, one of said armature-shafts projecting through its closure-plate, a semaphore-blade mounted on said last-named shaft-section, means mounted within the casing, and adapted to be engaged by said shaft-arm as the armature has reached its limit of movement in each direction to serve as a buffer therefor, circuit-closers mounted within the casing, and an arm secured to one of said armature-disks for operating the circuit-closers, each of said housing closer-plates having an aperture, a closure member for said apertures, means for detachably securing said last-named closure-plate members over the closure-plate apertures hermetically substantially as shown and described.

11. In a mechanism of the character stated, a housing, pole-pieces within the housing, energizing-coils carried by said pole-pieces, an armature mounted for rotary movement between the pole-pieces, circuit-closers within the housing, means within the housing for operating said circuit-closers, a semaphore-blade without the housing coöperatively connected to turn with the armature, substantially as shown and described.

12. In a mechanism of the character stated, a housing, pole-pieces within the housing, energizing-coils carried by said pole-pieces, an armature mounted for rotary movement between the pole-pieces, circuit-closers mounted within the housing, means within the housing for operating said circuit-closers, a semaphore-blade without the housing coöperatively connected to turn with the armature, said blade having a tailpiece provided with an indicating-glass, a supplemental housing below the first supplemental housing, a signal-lamp within said supplemental housing, said supplemental housing having apertures adapted to register with the tailpiece-glass when the semaphore is in one position.

809,238. **RAIL-JOINT.** ROBERT L. ALEXANDER, Moral, Okla., assignor of one-half to Albert Coleman, McComb, Okla. Filed Apr. 10, 1905. Serial No. 254,833.



Claim.—A railway-rail having formed on one end a longitudinally-projecting head and slotted web, and on its opposite end a longitudinally-projecting web and flange, said web and flange having formed therein a longitudinally-extending mortise to receive the longitudinally-projecting web of the next adjacent rail-section, the sides of said mortise web having formed therein oppositely-disposed rectangular apertures to alinse with the rectangular slots in the web of the adjoining section, pins having square shanks adapted to be projected through the alined apertures and slots in said web, said pins having bifurcated outer ends adapted to be bent into engagement with the adjacent sides of said webs, thereby securing said pins in place, substantially as described.

809,239. **CLOTH-TENSION DEVICE FOR TAKE-UP MECHANISM FOR LOOMS.** CLINTON S. ANDREW, North Grosvenor Dale, Conn. Filed Feb. 24, 1904. Serial No. 196,005.

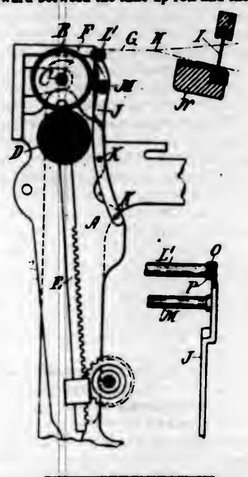
Claim.—1. In a cloth-tension device for looms, the combination of the high take-up roll, and the roll upon which the cloth is wound, with a tension-bar which serves to deflect the cloth from its progressive plane extending outward from the fell, and is located between the vertical plane of the axis of the take-up roll and the plane of the front face of the lay-beam inside of the breast-beam.

2. In a cloth-tension device for looms, the combination of the high take-up roll and the roll upon which the cloth is wound with the parallel tension-bars which serve to deflect the cloth downward from its progressive plane extending outward from the fell, and thence to the take-up roll, and located between the vertical plane of the axis of the take-up roll, and the plane of the front face of the lay-beam inside of the breast-beam.

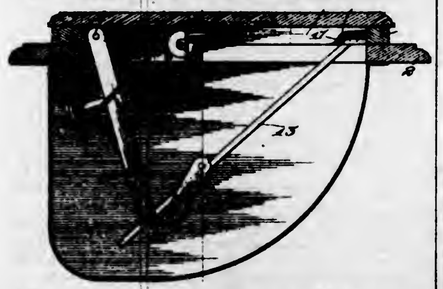
3. In a cloth-tension device for looms, the combination of a take-up roll, and a roll upon which the cloth is wound with a flexible resilient guide-bar, adapted for lateral deflection upon the opening of the shed, and over the surface of which the cloth primarily passes in its progressive movement from the fell to the take-up roll.

4. In a cloth-tension device for looms, the combination of a take-up roll, and a roll upon which the cloth is wound, with a flexible resilient guide-bar, for primarily deflecting the cloth from the plane of the fell.

5. In a cloth-tension device for looms, the combination of the high take-up roll, and the roll upon which the cloth is wound, with a flexible resilient guide-bar, which deflects the cloth from the plane of the fell, downward between the take-up roll and the lay.



809,240. **SEWING-MACHINE CABINET.** GUSTAV BAUMANN, Chicago, Ill., assignor, by direct and mesne assignments, to Illinois Sewing Machine Company, Chicago, Ill.; White Sewing Machine Company, Cleveland, Ohio, and Davis Sewing Machine Company, Dayton, Ohio. Original application filed Aug. 8, 1903, Serial No. 168,893. Divided and this application filed June 10, 1905. Serial No. 264,667.

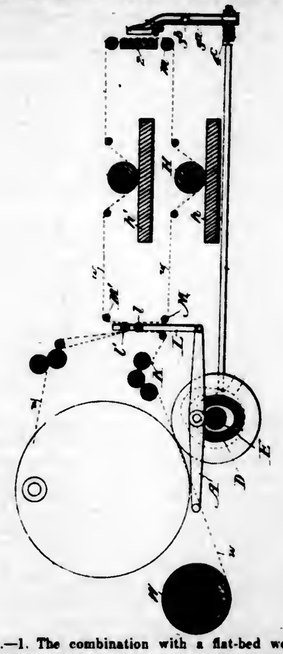


Claim.—1. In a device of the class described the combination with the table-top having an opening through it, a platform hinged at one side of said opening, a hinged leaf adapted to cover said opening, and means for transmitting movement from said hinged leaf to said platform, of a leaf operatively connected to the free side of the platform, a rest for the free side of said leaf, and a stationary guide fixed to the cabinet and engaging the leaf for automatically directing its free side onto the rest, substantially as described.

2. In a sewing-machine cabinet the combination with the table-top having an opening therethrough, of a platform hinged to the top at one side of said opening to swing from a position below said opening to a position partially closing said opening, a leaf adapted to coact with said platform and complete the closure of said opening, means whereby said platform when swung actuates said leaf, and an inclined guide fixed below the top of the table in position to engage said leaf and guide the same from a position below the opening to a horizontal position within the opening, substantially as described.

3. In a lift and drop head sewing-machine cabinet the combination with a table having an opening through it, of a machine-head platform hinged to said table within said opening at one side thereof and adapted to close said opening or to move below it, said platform consisting of two hinged portions which fold in the drop movement of the platform and thereby reduce its width when lowered, and a stationary guide, below the table-top, inclined from bottom to top toward the side of said opening opposite that at which the machine-head platform is hinged and terminating at its upper end, adjacent to the table-top, in a curvature in the same direction, whereby the free side of the hinged leaf is directed into the opening in the table-top and when nearing its uppermost position is directed into a horizontal position within said opening, substantially as described.

809,241. **FLAT-BED WEB-PRINTING PRESS.** HENRY F. BECHMAN, Battlecreek, Mich., assignor to The Duplex Printing Press Company, Battlecreek, Mich. Filed Feb. 11, 1905. Serial No. 245,238.



Claim.—1. The combination with a flat-bed web-perfecting press having two separated printing-couples, of a supplemental printing mechanism arranged to operate upon the web at a point intermediate the first and second printing mechanism.

2. The combination with a press having a plurality of separated printing mechanisms each comprising a bed and coacting cylinder adapted to successively print a web, of a supplemental printing device adapted to operate upon the web intermediate the said printing mechanisms.

3. The combination with a web-perfecting press having a plurality of separated printing mechanisms each comprising a coacting bed and cylinder, of a supplemental printing mechanism comprising a platen and a reciprocating bed, and arranged to operate upon the part of the web intermediate the first-mentioned printing mechanisms.

4. The combination of a web-perfecting press having a pair of stationary beds and reciprocating cylinders adapted to perfect the web; with a platen-press arranged intermediate the first and second beds and cylinders, and adapted to operate upon the portion of the web intermediate said beds and cylinders.

5. The combination with a flat-bed web-perfecting press, comprising a pair of separated stationary beds and coacting cylinders adapted to successively operate upon the web, of a supplemental printing mechanism, comprising a platen and a reciprocating type-carrier, arranged to operate upon the portion of the web intermediate the first and second impression-cylinders.

6. In combination with a duplex flat-bed web-perfecting press having a pair of parallel beds, a pair of reciprocating cylinders respectively coacting with said beds and means for feeding the web of paper successively between the beds and cylinders to be perfected thereby, of a reciprocating printing mechanism at one end of the beds adapted to operate upon the portion of the web between the first and second cylinders.

7. The combination with a duplex press having a pair of stationary beds and coacting cylinders, means for continuously feeding the web to and from said press, means for directing the web successively between the beds and cylinders to be perfected thereby and means for intermittently moving the intermediate part of the web through the printing mechanism; of a third printing mechanism located at a point intermediate the first and second type-beds and adapted to operate upon the intermediate part of the web while it is momentarily stationary.

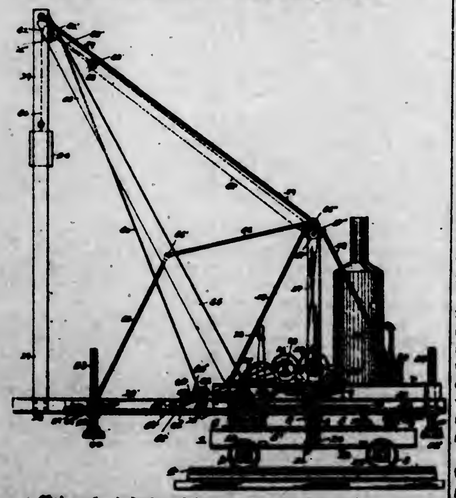
8. The combination of a stationary bed, a reciprocating cylinder, means for feeding the web continuously to and from the press, and a pair of devices for looping the web between the feed and delivery and whereby it may be intermittently shifted over the bed; with a supplemental printing mechanism arranged to operate upon the web at a point intermediate the looping devices.

9. The combination of a stationary bed, a reciprocating cylinder, means for feeding the web continuously to and from the press, and two separated devices for looping the web between the feed and delivery, and whereby it may be intermittently shifted over the bed; with a stationary bed and a reciprocating type-carrier arranged to operate upon the web at a point intermediate the looping devices, and a cam operated by the looping cam-shaft for actuating said type-carrier.

10. The combination with a press comprising upper and lower stationary type-beds, a pair of reciprocating cylinders respectively coacting with said type-beds, web-guiding mechanism for directing a web successively between the beds and cylinders, means for feeding the web to and from the press, and mechanism for looping the web to shift a portion thereof intermittently between the beds and cylinders, of a stationary platen and a reciprocating type-carrier located in the path of the web intermediate the first and second cylinders, and a reciprocating bar connected with the reciprocating type-carrier and arranged to operate the latter while a portion of the web in the press is momentarily stationary.

11. The combination with a press comprising upper and lower stationary type-beds, a pair of reciprocating cylinders respectively coacting with said type-beds, web-guiding mechanism for directing a web successively between the beds and cylinders, means for feeding the web to and from the press, devices for looping the web to shift a portion thereof intermittently between the beds and cylinders, and a shaft and cams for operating the looping devices; of a stationary platen and a reciprocating type-carrier, located in the path of the web intermediate the first and second cylinders, a reciprocating bar connected with the reciprocating type-carrier, and cams on the said shaft adapted to operate the bar, substantially as described.

809,242. **PILE-DRIVER.** ABRAHAM BISHOP, Pittsburg, Pa. Filed May 27, 1904. Renewed Dec. 4, 1905. Serial No. 288,202.



Claim.—1. A device of the type described, comprising a truck, a rotatable platform mounted thereon, and carrying drums driving-gearing on said platform, for operating said drums an engine on said platform and connected to said gearing for driving the same, a shaft extending under and parallel with said drums and having a gear-wheel thereon for engaging with the driving-gearing, an upright shaft having a beveled pinion thereon engaging with the beveled pinion on the first-named shaft, and connections from said upright shaft to the axles of the truck for moving said truck.

2. A device of the type described, comprising a truck, a rotatable platform mounted thereon, and carrying drums driving-gearing on said platform, for operating said drums an engine on said platform and connected to said gearing for driving the same, a shaft extending under and parallel with said drums and having a gear-wheel thereon for engaging with the driving-gearing, an upright shaft having a beveled pinion thereon engaging with the beveled pinion on the first-named shaft, and connections from said upright shaft to the axles of the truck for moving said truck.

3. A device of the type described, comprising a truck, a rotatable platform mounted thereon, and carrying drums driving-gearing on said platform, for operating said drums an engine on said platform and connected to said gearing for driving the same, a shaft extending under and parallel with said drums and having a gear-wheel thereon for engaging with the driving-gearing, a beveled pinion on said shaft, an upright shaft between said truck and platform having beveled pinions at each end thereof and the upper one of said pinions engaging with the beveled pinion on the first-named shaft, and connections from the lower one of said beveled pinions to the axles of the truck for moving said truck.

4. A device of the type described, comprising a truck, a rotatable platform mounted thereon, and carrying drums driving-gearing on said platform, for operating said drums an engine on said platform and connected to said gearing for driving the same, a shaft extending under and parallel with said drums and having a gear-wheel thereon for engaging with the driving-gearing, a beveled pinion on said shaft, an upright shaft between said truck and platform having bevel-pinions at each end thereof and the upper one of said pinions engaging with the beveled pinion on the first-named shaft, a shaft below said upright shaft having a beveled pinion thereon engaging with the beveled pinion on the lower end of the upright shaft, and gearing connecting said last-named shaft with the axles of the truck for moving said truck.

5. A device of the type described, comprising a truck, a rotatable platform mounted thereon, and carrying drums driving-gearing on said platform, for operating said drums an engine on said platform and connected to said gearing for driving the same, a shaft extending under and parallel with said drums and having a gear-wheel thereon for engaging with the driving-gearing, a beveled pinion on said shaft, an upright shaft between said truck and platform having beveled pinions at each end thereof and the upper one of said pinions engaging with the beveled pinion on the first-named shaft, a shaft below said upright shaft having a beveled pinion thereon engaging with the lower one of the beveled pinions on the upright shaft, and worm-gears on said last-named shaft engaging with worm-wheels on the axles of the truck for moving said truck.

6. A device of the type described, comprising a truck, a platform mounted on said truck, and carrying drums driving-gearing on said platform, for operating said drums an engine on said platform and connected to said gearing for driving the same, a shaft extending under and parallel with said drums and having a gear-wheel thereon engaging with said driving-gearing, and connections from said shaft for rotating the platform on the truck.

7. A device of the type described, comprising a truck, a platform mounted on said truck, and carrying drums driving-gearing on said platform, for operating said drums an engine on said platform, and connected to said gearing for driving the same, a shaft extending under and parallel with said drums and having a gear-wheel thereon engaging with said driving-gearing, a worm-rack on said truck, and a worm-gear on said shaft and engaging with said worm-rack for rotating said platform on the truck.

8. A device of the type described, comprising a truck, a platform mounted on said truck, and carrying drums driving-gearing on said platform, an engine on said platform for operating said drums and connected to said gearing for driving the same, a shaft extending under and parallel with said drums and having a gear-wheel thereon engaging with said driving-gearing, a worm-rack on said truck, a worm-gear on said shaft and adapted to engage said worm-rack, and a clutch on said shaft for engaging with said worm-gear to rotate said platform on said truck.

9. A device of the type described, comprising a truck, a rotatable platform mounted on said truck, and carrying drums driving-gearing on said platform, an engine on said platform and connected to said gearing for driving the same, a shaft extending under and parallel with said drums and having a gear-wheel thereon engaging with said driving-gearing, and means on said platform and operated from said shaft for raising said platform to permit the truck to be rotated on said platform.

10. A device of the type described, comprising a truck, a rotatable platform mounted on said truck, and carrying drums driving-gearing on said platform, an engine on said platform and connected to said gearing for driving the same, a shaft extending under and parallel with said drums and having a gear-wheel thereon engaging with said driving-gearing, jacks mounted on said platform, and means connecting said shaft and jacks for raising said platform to permit the trucks to be rotated on said platform.

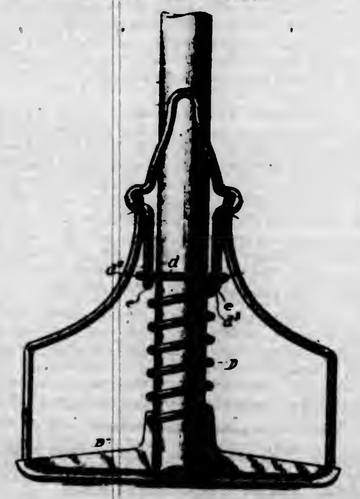
11. A device of the type described, comprising a truck, a rotatable platform mounted on said truck, and carrying drums driving-gearing on said platform, an engine on said platform and connected to said gearing for driving the same, a shaft having a gear-wheel thereon engaging with the driving-gearing, jacks mounted on said platform and provided with screw-bars thereon, and means connecting said shaft and screw-bars for operating said jacks to raise said platform and permit the trucks to be rotated on said platform.

12. A device of the type described, comprising a truck, a rotatable platform mounted on said truck, driving-gearing on said platform, an engine on said platform and connected to said gearing for driving the same, a shaft having a gear-wheel thereon engaging with the driving-gearing, jacks mounted on said platform and provided with screw-bars thereon, worm-wheels on said screw-bars, worm-gears mounted on shafts and engaging with said worm-wheels, and means connecting said first-named shaft with the worm-gear shafts for operating said jacks to raise said platform and permit the truck to be rotated on said platform.

13. A device of the type described, comprising a truck, a rotatable platform mounted on said truck, driving-gearing on said platform, an engine on said platform and connected to said gearing for driving the same, a shaft having a gear-wheel thereon engaging with the driving-gearing, jacks mounted on said platform and provided with screw-bars thereon, worm-wheels on said screw-bars, worm-gears mounted on shafts and engaging with said worm-wheels, a beveled pinion on said first-named shaft engaging with a beveled pinion on one of the worm-wheel shafts, and shaft and gearing connections from said worm-wheel shaft to the other worm-wheel shafts for operating said jacks to raise said platform and permit the trucks to be rotated on said platform.

14. A device of the type described, comprising a truck, a platform mounted on said truck, driving-gearing on said platform, an engine on said platform and connected to said gearing for driving the same, uprights carried from said platform, a ram on said uprights, a detachable portion on said platform connected to said uprights, and a boom pivoted to the permanent portion of said platform and removably connected to said uprights.

809,243. **MOP-HOLDER.** HARRY BITNER, Berwyn, Ill., assignor to Arcade Manufacturing Company, Freeport, Ill., a Corporation of Illinois. Filed Mar. 31, 1904. Serial No. 201,192.



Claim.—1. The combination with a stick, a cross-head on the end of the stick, and a bail guided on the cross-head and extending therefrom along the stick, of a spring on the stick above the cross-head, one of the upper coils of said spring being provided with oppositely-extending U-shaped bends, and a lever pivoted upon said U-shaped bends and connected with the upper ends of the bail.

2. The combination with a stick, a cross-head on the lower end thereof, and a bail guided on the cross-head and extending therefrom along the stick, of a lever pivotally supported at its lower end adjacent to the stick, said lever being formed of wire having oppositely-extending U-shaped bends and suitable connections with the bail pivoted upon said U-shaped bends.

3. The combination with a stick, a cross-head on the lower end thereof, and a bail guided on the cross-head and extending therefrom along the stick, of a lever pivotally supported at its lower end adjacent to the stick, said lever being formed of wire having oppositely-extending U-shaped bends and eyes upon the upper ends of the bail, pivoted upon said U-shaped bends.

4. The combination with a stick, a cross-head on the end of the stick and a bail guided on the cross-head and extending therefrom along the stick, of a spring on the stick above the cross-head, a lever bent into approximately U shape, having a bearing at its lower end upon the upper portion of the spring, and having laterally-extending U-shaped bends by means of which it is pivoted to the upper ends of the bail.

5. The combination with a stick, a cross-head on the end of the stick, and a bail guided on the cross-head and extending therefrom along the stick, of a spring on the stick above the cross-head, one of the upper coils of said spring having laterally-extending U-shaped bends and the wire adjacent to the upper bend brought down toward the next coil of the spring to afford a bearing thereon, and a lever pivoted upon said U-shaped bends and connected to the upper end of the bail.

6. The combination with a stick, a cross-head on the end of the stick, and a bail guided on the cross-head and extending therefrom along the stick, of a spring on the stick above the cross-head, one of the upper coils of said spring being formed with oppositely-extending U-shaped bends, and an approximately U-shaped wire lever pivoted by means of the ends of the wire upon the U-shaped bends, and having, between its ends, laterally-extending U-shaped bends upon which the upper ends of the bail are pivoted.

809,244. **CLOTHES-TONGS.** FRANK L. BLOSQUIST, Sanders, Idaho. Filed Apr. 18, 1904. Serial No. 203,734.

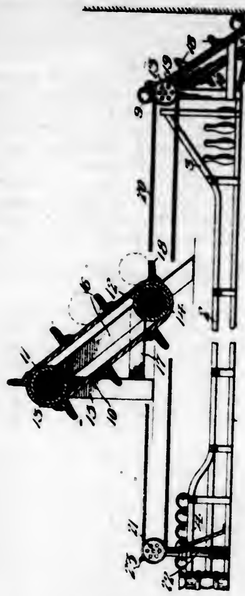
Claim.—A device of the character described comprising two similar jaw members, each provided at its upper end with a comparatively short half-round shank portion, these shank portions being rigidly secured together in flat engagement with each other to form a single round shank or handle for the tongs, the main portions of the two jaw members being of substantially similar cross-sectional shape with said shank members and diverging slightly from each other as they extend downwardly from said handle, said jaws and shank portions having shoulders at their point of union with each other, said jaws being cut away on their inner flat sides at their upper ends to render them springy at that point.

809,245. **BALL-RETURN MECHANISM FOR BOWLING-ALLEYS.** FREDERICK W. BRINKMEYER, Decatur Ill. Original application filed Nov. 17, 1904, Serial No. 233,188. Divided and this application filed Mar. 25, 1905. Serial No. 251,045.

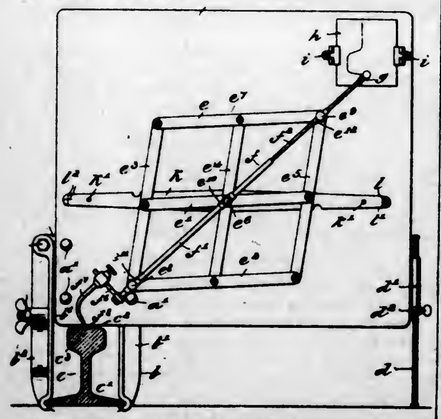
Claim.—1. A bowling-alley having a ball-runway provided at its rear end with a chute and at its forward end with a gallery or receiving portion, the rear end of the alley being provided with a downwardly and laterally inclined chute, an endless conveyer inclined upwardly and forwardly from the chute to the ball-runway and provided with pockets or cups to gather the balls from said chute and transfer them to the runway-chute, and means for operating said conveyer from a point adjacent to the gallery or receiving portion.

2. A bowling-alley having a ball-runway provided at its inner end with an inclined chute and at its forward end with a gallery or receiving portion, the rear end of the alley being provided at one side thereof with a ball-receiving pocket and a downwardly and lat-

erally inclined chute leading to said pocket, an inclined support leading from the pocket to a point adjacent the chute portion of the runway, a correspondingly-inclined endless conveyer mounted on said support and provided with pockets or cups to gather the balls from said receiving-pocket and conduct the same to the chute of the runway, and means for operating said conveyer from a point adjacent to the gallery or receiving portion of the ball-runway.



809,246. PANTOGRAPH. NATHANIEL H. BROWN, Philadelphia, Pa., assignor to Williams, Brown & Earle, Philadelphia, Pa. Filed July 8, 1905. Serial No. 268,796.



Claim.—1. In a pantograph, a movable frame, a holder, consisting of members slidable in each other and having a tracing-point and drawing means arranged at their respective free ends, said tracing-point being curved and pivotally secured to said holder and its free end arranged in the longitudinal central axis thereof to remain in alinement therewith during turning of said tracing-point around its holder and said tracing-point adapted to permit of the reproduction of its movements by said drawing means by expanding and contracting said holder by said frame.

2. In a pantograph, a movable frame, a holder, consisting of members slidable in each other and having a tracing-point and drawing means carried by said holder, said tracing-point curved and pivotally secured to said holder and its free end arranged in the longitudinal central axis to permit said tracing-point by turning on said holder to be moved over curved objects and to remain with its end in the longitudinal central axis of said holder and said tracing-point adapted to permit of the reproduction of its movements by said drawing means by the expanding and contracting of said holder by said frame.

3. In a pantograph, a movable frame, a holder, consisting of two members slidable in each other and having a tracing-point and a pencil carried by said holder at opposite ends, said tracing-point curved and pivotally secured to said holder and its free end arranged in the longitudinal central axis thereof to permit said tracing-point by turning on said holder to be moved over curved objects, and said pencil being adapted to be actuated by the movements of said tracing-point and by the sliding of said holder members within each other to reproduce a profile of the object.

4. In a pantograph, a frame consisting of a series of limbs movably joined to each other at their respective ends and a point intermediate thereof, a telescoping holder carried and actuated by said frame *e*, an arm pivotally secured to one end of said holder, a curved tracing-point slidably arranged on said arm and having an end arranged in the central longitudinal axis of said holder, and a pencil-holder arranged at the other end of said holder and having a pencil movably arranged therein.

5. In a pantograph, a board, a movable frame pivotally secured to said board, a holder having a tracing-point and a pencil carried by said frame, a clamp arranged at one side of said board and adapted to engage an object to be traced by said tracing-point and to be reproduced in profile by said pencil, and adjustable means arranged at the opposite side of said board, said means and clamp adapted to hold said board and frame in proper position with respect to said object.

6. In a pantograph, a board, a movable frame pivotally secured to said board, a holder having a tracing-point and a pencil carried by said frame, a clamp consisting of two members pivotally connected with each other and having gripping-jaws adapted to engage the object to be traced by said tracing-point and to be reproduced in profile by said pencil and to hold said board and frame in proper position thereto, and means adapted to hold the members of said clamp in engagement with the object.

7. In a pantograph, a board, a movable frame pivotally secured to said board, a holder carried by said frame and having at opposite ends a tracing-point and a pencil projecting from said holder beyond said frame, and a standardizing bar or aliner carried by said board having a post and markings arranged at opposite ends thereon, said markings and post adapted, when said pencil and tracing-points are respectively brought into alinement with the same to facilitate an adjustment of the tracing-point and pencil on said holder.

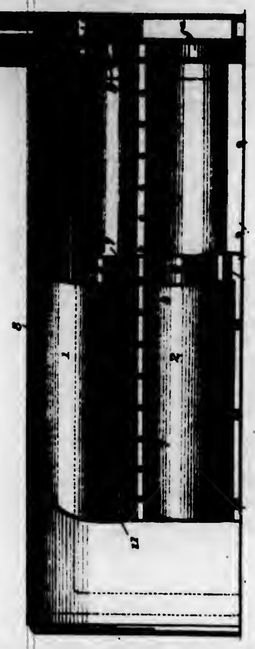
8. In a pantograph, a board, a frame consisting of a series of limbs movably joined to each other at their respective ends and at points intermediate thereto movably connected with said board, a holder, consisting of a tube and a rod movably secured to said frame, a tracing-point and pencil movably and adjustably secured to said tube and rod, and a clamp adapted to connect said board with the object to be drawn.

9. In a pantograph, a board, a frame consisting of a series of limbs movably joined to each other at their respective ends and at points intermediate thereto movably connected with said board, a holder, consisting of a tube and a rod movably secured to said frame, a tracing-point and pencil respectively movably and adjustably secured to said tube and rod, a clamp adapted to connect said board with the object to be drawn, and a standardizing bar or aliner carried by said board and arranged below said frame and having a post and markings arranged at opposite ends thereon and adapted to serve as a guide to bring said tracing-point and pencil back to their respective relative positions when away from the same.

10. In a pantograph, a board, a movable frame pivotally secured to said board, a holder for a tracing-point and pencil carried by said frame, a clamp secured to said board and adapted to connect the same to an object to be drawn by said tracing-point and to be reproduced by said pencil, and a rod movably secured to said board and adapted in conjunction with said clamp to support said board.

809,247. FIRE-BOX. FRANK BURGER and HENRY M. WILLIAMS, Fort Wayne, Ind.; said Burger assignor of one-half of his right to said Williams. Filed Mar. 14, 1902. Serial No. 98,321.

Claim.—1. A boiler consisting of two pairs of superposed shells, one pair inclosing the other with a space between them to form the water and steam space of the boiler, and the inner pair forming the fire-box, combined with a casing inclosing said shells with a space between them with which the fire-box is in communication, and a partition dividing said space into upper and lower chambers, substantially as set forth.



2. A boiler consisting of two pairs of superposed shells, one pair inclosing the other with a space between them to form the water and steam space of the boiler, and the inner pair forming the fire-box extending from end to end of the boiler, horizontal water-tubes extending across the fire-box and communicating with the interior of the boiler at each side thereof, and vertical tubes leading from the horizontal tubes through the crown-sheet of the fire-box, substantially as set forth.

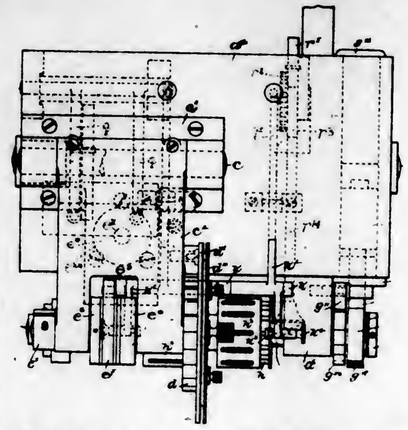
3. In a boiler, the combination with two pairs of superposed shells, one pair inclosing the other with a space between them, channel-irons secured to the shells of the respective pairs at their junctions, horizontal tubes secured in the channel-irons of the inner shells and forming stays therefor, and rods extending through said tubes and secured at their ends in the channel-bars of the outer shells, substantially as set forth.

4. In a boiler, the combination with superposed shells and channel-irons secured thereto at their junctions, of screw-plugs secured in said channel-irons at opposing points, and a rod passing loosely through one plug and having a threaded connection with the other, and nuts on the ends of the rod engaging the plugs substantially as set forth.

5. In a boiler, the combination with superposed shells and channel-irons secured thereto at their junctions, of screw-plugs secured in said channel-irons at opposing points, and a rod passing loosely through one plug and having a threaded connection with the other, nuts on the ends of the rod engaging the plugs, a casing inclosing said shells and having openings to afford access to said nuts and rods, and covers for said openings, substantially as set forth.

809,248. MACHINE FOR GAGING PIVOTS. DUANE H. CHURCH, Newton, Mass.; Harriet L. Church executrix of said Duane H. Church, deceased. Filed May 5, 1898. Serial No. 679,776.

Claim.—1. A machine of the character described comprising a holder having relatively movable members for holding a pivot against displacement, a plurality of gages each having an aperture differing in its known diameter from that of the others, and mechanism for automatically bringing said pivot and said gages into operative relation while said pivot is held or carried by the holder.



2. A machine of the character described, comprising a holder having clamps, for a pivot, a plurality of gages each having a jewel with an aperture of a known diameter, and automatic mechanism for bringing said pivot and said jewels into operative relation while said pivot is carried by said holder.

3. A machine of the character described comprising a holder having provisions for clamping a pivot therein, a plurality of gages each having a jewel with an aperture of a known diameter, and automatic mechanism for moving said gages in succession into operative relation to said pivot.

4. A machine of the character specified comprising a holder having relatively movable members having provisions for clamping the article being measured, measuring devices, and mechanism for causing said devices to measure the diameter of a part or feature of said article.

5. A machine of the character specified comprising a holder with provisions for clamping or securing the articles being measured, measuring devices, and mechanism for causing said devices to measure and record the diameter of a part or feature of said article.

6. A machine of the character described having a holder for the article to be measured and a plurality of measuring-gages for automatically measuring each of two different parts of said article.

7. A machine of the character described having a holder for the article to be measured and a plurality of measuring-gages for automatically measuring and independently recording the measurements of each of two different parts or features of said article.

8. A machine of the character described comprising a plurality of gages, a holder having relatively movable members independent of the gages for the articles to be measured, means for moving said holder to present said articles to each of said gages, and means for bringing each article and said gages successively into engagement until said article is measured.

9. A machine comprising a plurality of gages, a holder having relatively movable members independent of the gages for a plurality of articles to be measured, means for automatically moving said holder, and mechanism for automatically causing the pivot and gage to engage without dislocating said article from its holder.

10. A machine comprising a holder having relatively movable members for receiving and holding a pivot or thing to be measured, a plurality of graded gages, mechanism for advancing said gages automatically into operative relation to a pivot in the holder, and mechanism for causing said gages to measure said pivot without removing it from said holder.

11. A machine comprising a rotary holder having relatively movable members for receiving a pivot or thing to be measured, a carrier having a plurality of graded gages, mechanism for imparting a step-by-step movement to said holder to present the pivots or things to be measured successively to the gages, and mechanism for causing said gages to measure said pivot without removing it from said holder.

12. A machine for measuring the pivot on the end of a balance-staff; comprising a holder having provisions for receiving and rigidly holding said staff, a plurality of independent measuring devices for measuring the cross-diameter of the said pivot, and automatic mechanism for causing said holder to present said pivot to said measuring mechanism.

13. A machine having a holder having relatively movable members for receiving and rigidly holding a thing to be measured, a plurality of gages for measuring said thing, and means for causing said thing and said gages to be brought into operative relation.

14. A machine comprising a series of gages, a holder having relatively movable members for receiving and rigidly holding an article to be measured, mechanism for causing the article to be brought into operative relation to the gages until a gage corresponding to the article is reached.

15. A machine of the character described comprising a holder having relatively movable members for clamping an article to be measured, and a series of gages each movable into operative relation to said article.

16. A machine of the character described comprising a pivot-holder having provisions for clamping an article to be measured, a gage-carrier having a series of gages, and mechanism for moving said carrier to bring said gages successively into operative relation to an article.

17. A machine of the character described comprising a holder having relatively movable members for an article to be measured, a rotary carrier having a series of gages, and mechanism for imparting a step-by-step movement to the carrier to bring the gages successively into operative relation to said article.

18. A machine of the character described comprising a holder for the article to be measured, a carrier having a series of movable gages, mechanism for moving the carrier to bring the gages successively into alinement with said article, and mechanism for bringing the gages into contact with said article.

19. A machine of the character described comprising a holder, for the article to be measured, a series of independently-movable gages, mechanism for bringing said gages successively into engagement with said article, and automatic devices for holding the remaining gages out of contact with said article after a gage corresponding to said article has been engaged therewith.

20. A machine of the character described comprising a holder for the article to be measured, a series of movable gages, mechanism for bringing said gages successively into engagement with the said article, a feeler, in operative relation to said gages, and mechanism controlled by said feeler for governing the movement of the gages.

21. A machine of the character described comprising a holder for the article to be measured, a carrier, a series of graded gages mounted on said carrier and movable into engagement with said article, a pneumatic device for controlling the movement of the gages, and a feeler in operative relation to said gages for controlling the pneumatic device.

22. A machine of the character described comprising a holder for the article to be measured, a carrier having a series of movable gages, a pneumatic device for moving the gages, a regularly automatically moving valve controlling the passage of air to said pneumatic device, a feeler in operative relation to the gages, and supplemental devices controlled by the feeler for cutting the first said supply to the pneumatic device when a gage corresponding to the pivot is presented thereto.

23. A machine of the character described comprising a pivot-holder having relatively movable members, a series of automatically-acting measuring devices, each having an aperture of a known diameter, and means for bringing said pivots and said apertures successively into alinement.

24. A machine of the character described comprising a pivot-holder, a series of measuring devices, each consisting of a jewel having an aperture of a predetermined diameter, and automatic devices for moving and presenting them successively to the pivot.

25. A machine of the character described comprising a holder having means for clamping a pivot, a series of measuring devices, each having an aperture of a known diameter different from that of any of the others, and mechanism including a movable carrier for engaging said devices with the pivot, in order beginning with that having the aperture of the largest diameter.

26. A machine of the character described, comprising a recording device, a series of graded gages, mechanism for automatically presenting said gages one by one to the pivot to be measured, and mechanism for operating the recording device when a gage corresponding to the pivot is presented thereto.

27. A machine of the character described, comprising a work-holder, a series of graded gages, mechanism for presenting said gages one by one to the work carried by said holder, devices for holding a record-sheet, and devices for making a record of the diameter of each piece of work upon the sheet.

28. A machine of the character described, comprising a work-holder having relatively movable members, a series of graded gages, mechanism for presenting said gages one by one to the work carried by said holder, and a device having symbols designating the internal diameters of the gages and moving simultaneously with the gages.

29. A machine of the character described, comprising a work-holder, a series of graded gages, mechanism for presenting said gages, one by one, to the pivot, a device having symbols designating the internal diameters of the gages, and moving simultaneously with the gages, and mechanism for bringing a record-sheet against a symbol when a gage corresponding to the pivot is presented thereto.

30. A machine of the character described having provisions for automatically measuring and recording the diameter of a predetermined number of pivots in succession, and provisions for stopping the machine automatically when the diameters of said pivots have been recorded.

31. A machine of the character described comprising two independent sets of measuring devices and a carrier located between said sets of measuring devices for presenting the two pivots of a balance-wheel or other part of a watch simultaneously to the said devices.

32. A machine of the character described comprising a holder for the pivots to be measured, means for supporting a record-sheet, two independent sets of oppositely-arranged graded gages, and mechanism controlled by said gages for recording on said record-sheet the measurements of the pivots.

33. A machine of the character described comprising measuring devices, and a carrier for presenting the pivots to the said devices, said carrier consisting of two separable clamps having alined apertures to receive the pivots whereby said pivots are held rigidly while being measured.

34. A machine of the character described, comprising a pivot-carrier, two independent sets of measuring devices, means for supporting a record-sheet, a device having two sets of symbols, and placed in operative relation to the record-sheet, a feeler for each set of gages, and two independent hammers each controlled by one of the feelers, and each arranged to strike the record-sheet against one of the symbols.

35. A machine comprising recording mechanism, devices for measuring the diameter of the thing to be measured, means for automatically presenting the thing to be measured to the measuring device, and mechanism for operating the recording mechanism when the said thing is measured.

36. A machine comprising mechanism, for measuring the diameter of the thing to be measured and for recording the measurements, means for automatically presenting the thing to be measured to the measuring device, and mechanism controlled by the measuring devices for automatically operating the recording mechanism.

37. A machine of the character specified comprising a holder for the articles to be measured, a plurality of gages, a carrier for said gages, means for moving said gages to present them one by one to one of said articles, and means for moving said holder to present said articles in succession to said gages.

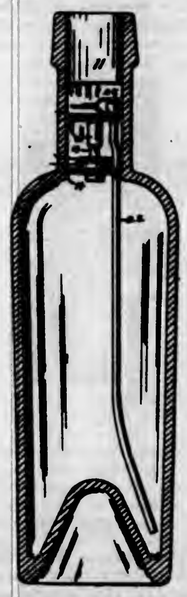
38. A machine of the character described comprising a holder for the article to be measured, measuring devices for ascertaining the diameter of said article, and pneumatic mechanism for automatically causing said devices to measure said article.

39. A machine of the character described comprising a holder having relatively movable members for the article to be measured, a plurality of gages, said article and said gages being adapted to pass one into the other, and means for causing said gages to successively move into operative relation to said article while it is in the holder without dislocating said article.

809,249. **NON-REFILLABLE BOTTLE.** FRANK J. DAVIS, Indianapolis, Ind., assignor, by direct and mesne assignments, to himself, John C. Walker, and Fred R. Tutsey, Indianapolis, Ind. Filed Mar. 26, 1904. Renewed June 12, 1905. Serial No. 264,962.

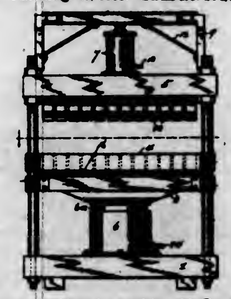
Claim.—1. In means insertible within a bottle to prevent its being refilled, a suitable valve-seat a hollow valve extending through and inwardly beyond said seat and open at its inner end, and means for closing said valve that is overcome by the gravity of the valve when filled with liquid.

2. In means insertible within a bottle to prevent its being refilled, a valve-seat, a hollow valve the outer end of which is conical to fit the valve-seat and the inner end of which is cylindrical and extends beyond the valve-seat and is open at its inner end, and means for closing said valve that is overcome by the gravity of the valve when filled with liquid.



3. A device for rendering a bottle non-refillable consisting of two disks, the lower one having a valve-seat and the upper one having an outlet-opening, a hollow valve fitting in said valve-seat with a central outward stem, a tubular guide extending centrally from the outer disk toward the valve-seat to receive the stem of the valve, a spring in said tubular guide acting against the valve-stem, an air-tube extending through both disks, a valve at the outer end of said air-tube for closing the same, and a protecting-cover mounted on the outer disk and extending substantially over the outlet through the outer disk and inlet into the air-tube, substantially as set forth.

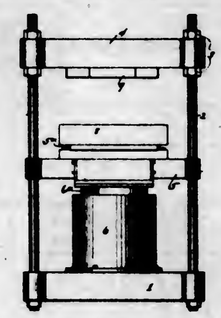
809,250. **CEMENT-BRICK MACHINE.** FRED B. DUBART, Superior, Nebr., assignor of two-thirds to C. B. Adams and A. C. Pelt, Superior, Nebr. Filed Aug. 12, 1905. Serial No. 274,726.



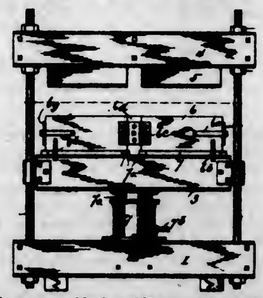
Claim.—In a machine for making blocks from material in plastic form, a bed-plate slidably mounted on a suitable frame, mold-boxes slidably mounted on said frame above said bed-plate, means for raising said bed-plate and mold-boxes, a header adjustably mounted on said frame, dies secured to the under side of said header, and means for raising said mold-boxes independently of said bed-plate.

809,251. **CEMENT-TILE MACHINE.** FRED B. DUBART, Superior, Nebr., assignor of two-thirds to C. B. Adams and A. C. Pelt, Superior, Nebr. Filed Aug. 12, 1905. Serial No. 274,726.

Claim.—In a machine of the class described, a base having vertical shafts secured thereto, a header-plate adjustably mounted on the upper part of said shafts, and means for locking said header in its adjusted position; a bed-plate slidably mounted on said shafts, a mold-box secured, to said bed-plate with a space between said box and said bed-plate, pallets slidably arranged in the space between the mold-box and the bed-plate, and a mold-box having hinged ends, and means for operating said bed-plate, all substantially as described.



809,252. **CEMENT-BLOCK MACHINE.** FRED B. DUBART, Superior, Nebr., assignor of two-thirds to C. B. Adams and A. C. Pelt, Superior, Nebr. Filed Aug. 14, 1905. Serial No. 274,727.



Claim.—In a cement-block-molding machine, a slidably-mounted bed-plate having supported thereon a mold-box formed with a central portion and provided with sides hinged on said central portion, also provided with ends hinged to one of said sides of the boxes and means for locking said end pieces on the opposite sides of the box, means for centering the mold-box on the bed-plate, and means for operating said bed-plate.

809,253. **DEVICE FOR CIRCULATING STEAM, &c.** FRANK C. GOFF, Denver, Colo. Filed Nov. 6, 1903. Serial No. 180,268.

Claim.—1. The combination with a heating system, of means connected with the air-outlet of the system for automatically controlling the supply of the heating agent, by the force of the air driven out of the system by said agent.

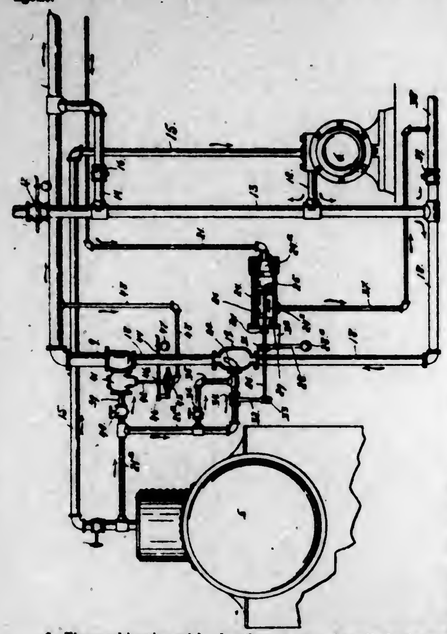
2. The combination with a steam-heating system, of means connected with the air-outlet of the system for automatically controlling the supply of the heating agent, by the suction produced in the system incident to steam condensation.

3. The combination with a steam-heating system, of means connected with the air-outlet of the system for automatically controlling the supply of the heating agent, by the action of the air driven out of the system by the heating agent, and the suction incident to steam condensation in the system.

4. The combination with a heating system, of a cylinder in communication with the air-valves to allow the air driven out of the system, to enter the cylinder, a piston in the cylinder, and means connected with the piston and actuated thereby for controlling the supply of the heating agent.

5. The combination with a heating system, of a cylinder in communication with the air-valves of the system to allow the air driven out of the system to enter the cylinder, a piston in the cylinder, and

a valve located in the system and connected with the cylinder-piston, whereby the valve is actuated to regulate the supply of the heating agent.



6. The combination with a heating system, of a cylinder in communication with the air-valves of the system, a piston in the cylinder, a lever connected with the piston-stem, a valve for controlling the heating agent, and connected with the piston-stem, the lever normally holding the valve closed, the piston-stem, however, being actuated by the movement of the piston as the latter is operated in response to the air-pressure or suction, substantially as described.

7. The combination with a heating system, of a cylinder in communication with the air-valves of the system, a piston in the cylinder, a valve located in the system for controlling the heating agent, and connected with the piston-stem, whereby the valve is automatically actuated by said stem, and a valve located in a by-pass of the system.

8. The combination with a heating system, of means in communication with the air-valves of the system for automatically controlling the supply of the heating agent to the system, by the normal action of the air driven out of the system by the heating agent, and the suction incident to condensation, and means interposed in the system for automatically controlling the supply of the heating agent to the system.

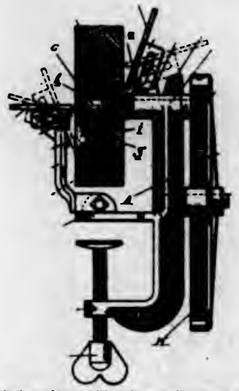
9. The combination with a heating system, of means in communication with the air-valves of the system for automatically controlling the supply of the heating agent to the system by the normal action of the air driven out of the system by the heating agent and the suction incident to condensation, and means interposed in the system for automatically controlling the supply of the heating agent to the system by the force of said agent in the system, said last-named means consisting of a valve and a weighted diaphragm, the latter being connected with the valve on one side and in communication with the heating agent on the opposite side.

10. The combination with a radiator, of means communicating with the air-outlet of the radiator for automatically controlling the supply of the heating agent thereto, by the force of the air driven out of the radiator by said agent.

11. The combination with a steam-radiator, of means communicating with the air-outlet of the radiator for automatically controlling the supply of the heating agent thereto by the suction produced in the radiator incident to steam condensation.

809,254. GRINDER. GEORGE W. GOLDEN, Detroit, Mich. Filed Jan. 3, 1903. Serial No. 137,412.

Claim.—1. In a grinder, the combination with a frame, an arbor journaled therein, a grinder-wheel mounted on said arbor, and a drive connection for revolving said arbor, of an adjustable guide arranged at the side of said wheel, and auxiliary means for limiting the adjustment of said guide to hold the same at a predetermined angularity.

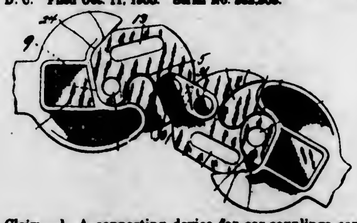


2. In a grinder, the combination with a frame, arbor journaled therein, grinder-wheel mounted upon said arbor, of a guide adjustably secured to said frame at one side of said grinder, and stops for limiting the angular adjustment of said guide, to hold the same in predetermined positions of adjustment for two different kinds of work.

3. In a grinder, the combination with an arbor, of a grinder-wheel mounted thereon and having a central recess, clamping means for securing said wheel on said arbor, arranged in said recess, completely below the surrounding surface of the grinder-wheel and a guide for the work on the recessed side of said wheel.

4. In a grinder, a frame comprising a vertical bar and clamped at the lower end of said bar, a journal-bearing at the upper end of said bar, an arbor in said bearing, a grinder-wheel on said arbor, the clamping means being countersunk below the surface of the grinder-wheel, a pinion mounted on the opposite end of said arbor, a drive-gear intermeshing with said pinion, and a rearwardly-projecting lug on said frame, upon which said drive-gear is journaled, whereby the periphery of said drive-wheel is arranged to clear the front face of the grinder-wheel.

809,255. CAR-COUPLING. WILLIAM W. GORDON, Washington, D. C. Filed Oct. 11, 1905. Serial No. 282,208.



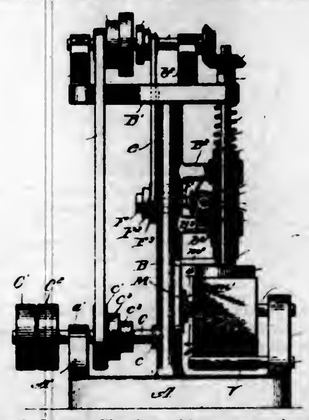
Claim.—1. A connecting device for car-couplings comprising two coupling sections or heads, each of which is provided with a coupling-hook adapted to engage with the respective coupling-knuckles of adjacent cars, and one of said coupling-sections being provided with a shouldered portion at its rear end adapted to project within the slot of a draw-head to hold said coupling-section in position and prevent the same from dropping away from the draw-head, and a pivotal connection between the coupling-sections.

2. A connecting device for car-couplings comprising two coupling sections or heads, each of which is provided with a coupling-hook adapted to engage with the respective coupling-knuckles of adjacent cars, and a pivot-bolt passing through alined apertures in the coupling-sections.

3. A connecting device for car-couplings comprising two coupling sections or heads, each of which is provided with a coupling-hook adapted to engage with the respective coupling-knuckles of adjacent cars, one of said coupling-sections having a shouldered portion at its rear end adapted to project within the slot of a draw-head to hold said coupling-section in position and prevent the same from dropping away from said draw-head, and a pivot-bolt passing through alined apertures in the coupling-sections.

4. A connecting device for car-couplings comprising two coupling sections or heads, each of which is provided with a hook adapted to engage with the respective knuckles of adjacent cars, one section being horizontally slotted to partially receive the other section in the swinging movements of the latter, and a pivot-bolt passing through alined apertures in the said sections.

809,256. MACHINE FOR MAKING GASKETS. JAMES W. GUILLOTT, Chicago, Ill. Filed Feb. 6, 1905. Serial No. 244,426.



Claim.—1. In a machine for making corrugated gaskets, the combination with a plate having concentric corrugations, of a die having corrugations corresponding to those of said plate, means for relatively rotating said die and said plate, and automatic means for intermittently reciprocating said die toward and away from said plate.

2. In a machine for making corrugated gaskets, the combination with a plate having concentric corrugations, of a die having corrugations to correspond to those of said plate, a carrier for supporting said die, means for rotating said carrier relative to said plate, and automatic means for intermittently moving said carrier and plate toward and away from each other.

3. In a machine for making corrugated gaskets, the combination with a plate having concentric corrugations, of a die having corrugations corresponding to those of said plate, a carrier for supporting said die, a cutter mounted upon said carrier, means for rotating said carrier relatively to said plate, and means for intermittently reciprocating said carrier toward and away from said plate.

4. In a machine for making corrugated gaskets, the combination with a plate having concentric corrugations, of a roller having corrugations corresponding to those of said plate, a carrier upon which said roller is journaled, means for rotating said carrier relatively to said plate, and automatic means for intermittently reciprocating said carrier toward and away from said plate.

5. In a machine for making corrugated gaskets, the combination with a plate having concentric corrugations, of a roller having corrugations corresponding to those of said plate, a carrier upon which said roller is journaled, a cutting-disk journaled upon said carrier, means for rotating said carrier relatively to said plate, and means for intermittently reciprocating said carrier toward and away from said plate.

6. In a machine of the character described, the combination with a plate having concentric corrugations, a carrier located adjacent said plate, radial rods upon said carrier, rollers journaled upon said rods having corrugations corresponding with those of said plate, cutting-disks journaled upon said rods, means for rotating said carrier relatively to said plate, and means for intermittently moving said carrier and plate toward and away from each other.

7. In a machine of the character described, the combination with a plate having concentric corrugations, a carrier located adjacent said plate, radial rods upon said carrier, rollers journaled upon said rods having corrugations corresponding with those of said plate, cutting-disks journaled upon said rods, a corrugated disk fixed concentrically to said carrier and located between the inner ends of said rollers, means for rotating said carrier relatively to said plate, and means for intermittently moving said carrier and plate toward and away from each other.

8. In a machine of the character described, the combination with a plate having concentric corrugations, a die having corrugations corresponding to those of said plate, a carrier for said die, a shaft to which said carrier is fixed, means for rotating said shaft, a sleeve loosely surrounding but longitudinally immovable relatively to said shaft, and means engaging said sleeve for intermittently reciprocating said carrier.

9. In a machine of the character described, the combination with a plurality of plates each having concentric corrugations, of a die having corrugations corresponding to those of said plates, means for rotating said die relatively to said plate, means for successively locating each of said plates beneath said die, and means for intermittently reciprocating said die toward and away from the adjacent plate.

10. In a machine of the character described, the combination with a plurality of plates each having concentric corrugations, a rotary table upon which said plates are supported, a die having corrugations corresponding to those of said plates, means for rotating said table to successively locate said plates beneath said die, and means for intermittently reciprocating said die toward and away from the adjacent plate.

11. In a machine of the character described, the combination with a rotary table, of a plurality of plates each having concentric corrugations, a die having corrugations corresponding with those of said plates, a carrier supporting said die, means for rotating said carrier, and means for intermittently reciprocating said carrier away from said table and coincidently rotating said table to locate a following plate beneath said carrier.

12. In a machine of the character described, the combination with a square table journaled to rotate in a vertical plane, a plate having concentric corrugations secured to each face of said table, a die having corrugations corresponding to those of said plates, means for rotating said die relatively to the coöperating plate, means for intermittently reciprocating said die away from said table and coincidently rotating said table to locate a following plate beneath said die.

13. In a machine for making corrugated gaskets, the combination with a plate having concentric corrugations, of a die having corrugations corresponding to those of said plate, means for rotating said die relatively to said plate, means for intermittently reciprocating said die toward and away from said plate, and means for automatically interposing sheet-copper between said die and plate.

14. In a machine of the character described, the combination with a square table journaled to rotate in a vertical plane, a plate having concentric corrugations secured to each face of said table, a die having corrugations corresponding to those of said plates, means for intermittently reciprocating said die away from said table and coincidently rotating said table to locate another plate beneath said die, and means for automatically securing a sheet of copper to said table.

15. In a machine of the character described, the combination with a square table journaled to rotate in a vertical plane, a plate having concentric corrugations secured to each face of said table, a die having corrugations corresponding to those of said plates, radially-reciprocating pins carried by said tables, means for projecting said pins through said plates to engage copper sheet and secure the same to said table, and means for disengaging said pins from the copper plate.

16. In a machine for making corrugated gaskets, the combination with a plate having corrugations, of a die having corrugations corresponding to those of said plate, a carrier for supporting said die, a plurality of cutters mounted upon said carrier at different distances from its axis, and means for relatively rotating said carrier and plate.

17. In a machine for making corrugated gaskets, the combination with a plate having concentric corrugations, of a die having corrugations corresponding to those of said plate, a carrier for supporting said die, a cutter mounted upon said carrier, means for radially adjusting the position of said cutter upon said carrier, and means for relatively rotating said carrier and said plate.

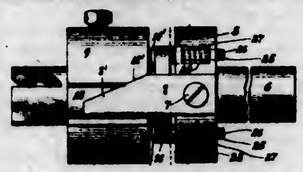
18. In a machine for making corrugated gaskets, the combination with a plate having concentric corrugations, of a plurality of rollers having corrugations corresponding to those of said plate, a carrier upon which said rollers are journaled, a plurality of cutting-

disks journaled upon said carrier and located different distances from its axis, means for relatively rotating said carrier and said plate, and means for relatively moving said carrier and plate toward and away from each other.

19. In a machine of the character described, the combination with a plate having concentric corrugations, a carrier located adjacent said plate, radial rods upon said carrier, rollers journaled upon said rods having corrugations corresponding with those of said plate, means for relatively rotating said carrier and said plate, and means for relatively moving said carrier and plate toward and away from each other.

20. In a machine of the character described, the combination with a plate having concentric corrugations, a carrier located adjacent said plate, radial rods upon said carrier, rollers journaled upon said rods having corrugations corresponding with those of said plate, cutting-disks journaled upon said rods at different distances from the axis of said carrier, means for adjusting said cutting-disks radially with respect to said carrier, means for relatively rotating said carrier and plate, and means for relatively moving said carrier and plate toward and away from each other.

809,257. **TOOL-HOLDER.** ERNST M. W. HANSON, Hartford, Conn., assignor to Pratt & Whitney Company, Hartford, Conn., a Corporation of New Jersey. Filed Aug. 9, 1905. Serial No. 273,479.



Claim.—1. The combination, with a fixed member, of a member movable thereon and carrying a screw-cutting tool; a yielding device carried by one of the members; and an adjustable collar on the other member adapted to engage said yielding device when the tool engages the work.

2. The combination, with a fixed member, of a tool-carrying member having a stem movable with respect to said fixed member; a collar on said stem and yielding devices between the collar and the fixed member, said yielding devices serving to permit the tool to engage the work under yielding pressure.

3. The combination, with a fixed member having a head provided with a series of chambers, of a movable member mounted on the fixed member; spring-actuated plungers carried in the chambers of the fixed member; and a device carried by the movable member and adapted to engage said plungers when the tool comes into contact with the work.

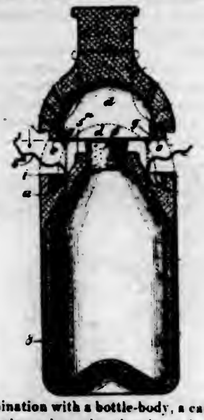
4. The combination, with a fixed member having a tubular shank, of spring-actuated plungers carried by said fixed member; a movable member having a stem inserted in the tubular shank of the fixed member; and a stop disk or projection secured to said stem, and bearing against the heads of said plungers.

5. The combination, with a fixed member having a tubular shank, and provided with a head having a series of chambers, of spring-actuated plungers operable in said chambers; a movable member having a stem fitted in the tubular shank of the fixed member; and a stop disk or projection adjustably secured to said stem, and receiving the impact of the spring-actuated plungers.

809,258. **BOTTLE-CLOSURE.** JACOB HEMMERDEN, Houston, Tex., assignor of one-half to John De Philippi, Houston, Tex. Filed Apr. 6, 1905. Serial No. 254,617.

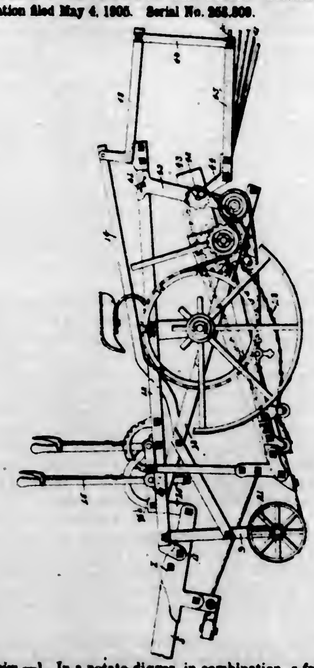
Claim.—1. The combination with a bottle-body open at the top, and a plug in said opening, of a cap-piece having a cavity in its lower side affording clearance from the plug when seated on said bottle-body, the cap-piece having lateral perforations extending outward from the cavity therein, and a locking-strand in the body of the bottle extended at its ends up into the cavity of the cap-piece and thence outward through the lateral perforations therein, said ends being secured in the perforations.

2. The combination with a cylindrical bottle-body having a short neck thereon, said neck having an annular recess encircling its lower end, and a plug closing the neck, of a dome-shaped cap-piece having lateral perforations in its side wall and provided with an annular depending flange that seats in the annular recess, and a locking-strand in the wall of the bottle-body, the ends of said strand being inserted into the lateral perforations and therein secured.



3. The combination with a bottle-body, a cap-piece securable on said body over a plugged opening therein, and means for removably securing the cap-piece on the body, of a label or the like secured over the joint between the cap-piece and the bottle-body, so that the fracture of the label will expose the removal of the cap-piece.

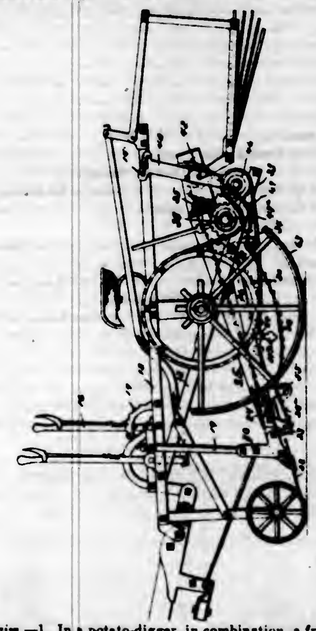
809,259. **POTATO-DIGGER.** JOHN HEIT, Solon, Ohio. Original application filed Feb. 11, 1905, Serial No. 245,926. Divided and this application filed May 4, 1905. Serial No. 258,809.



Claim.—1. In a potato-digger, in combination, a frame having upper and lower bars, arms hinged to the rear ends of the lower bars and adjustably connected to the rear ends of the upper bars, a shaft carried by said arms and having cranks at the ends, and a shaker suspended from the upper bars and connected to the cranks.

2. In a potato-digger, in combination, a frame having upper bars, arms depending from said bars, a crank-shaft carried by said arms, a shaker hung at the front end from said cranks, and levers fulcrumed on the rear ends of the bars and connected by links to the rear end of the shaker.

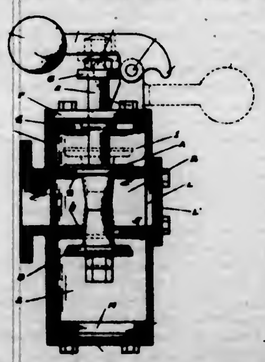
809,260. **POTATO-DIGGER.** JOHN HEIT, Solon, Ohio. Original application filed Feb. 11, 1905, Serial No. 245,926. Divided and this application filed May 9, 1905. Serial No. 259,861.



Claim.—1. In a potato-digger, in combination, a frame having upper bars 12, bars 13 secured thereto and inclined down and back, the side bars 26 pivoted to said bars 13, an endless carrier supported by said side bars, and arms 40 extending between the rear ends of the bars 12 and 13 and supporting the rear end of the carrier, and having wheels around which the carrier extends, and adjustable to vary the tension of the carrier.

2. In a potato-digger, the combination with a main drive-chain and an endless carrier, of an adjustable arm, separate shafts mounted upon the arm, sprockets carried by the shafts and around which the drive-chain and the carrier respectively extend, another shaft having thereon a sprocket engaged with the chain and another engaged with the carrier, and a clutch between the last-mentioned shaft and one of the sprockets thereon.

809,261. **VALVE FOR GAS-PRODUCERS.** FRANKLIN G. HOBART, Beloit, Wis., assignor to Fairbanks Morse & Company, Chicago, Ill., a Corporation of Illinois. Filed May 3, 1905. Serial No. 258,498.



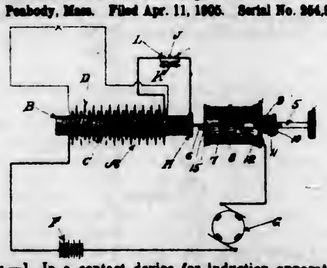
Claim.—1. In a valve for a gas-producer, the combination with a chambered casing having an inlet and opposed outlet-openings, of valves seating from the outside adapted to close said outlets, a stem on which said valves are mounted, one end thereof being extended loosely through said casing, and a weight pivoted on the outside of said casing and adapted to normally rest on the end of said valve-stem, for the purpose described.

2. In a valve for a gas-producer, the combination with a casing having a chamber open to the atmosphere, a chamber forming a pocket for collecting dust and open to the scrubber or other part of the apparatus, and an intermediate inlet-chamber open to the generator, the dividing-walls having opposed openings, of valves adapted to seat on the outer sides of said openings, a stem on which said valves are mounted having one end extended and passing loosely through the casing, and a weight pivoted on the outside of said casing and adapted to rest on the end of said stem to normally close the valve between the inlet-chamber and the chamber open to the atmosphere.

3. A valve consisting of a valve-casing, a vertically-removable stem extending outside of said casing, the movable elements of the valve mounted thereon, a lever pivoted on said casing and arranged to hold the valve closed in one extreme position and open at its opposite extreme position by gravity, substantially as described.

4. The mechanism for operating a vertical spindle-valve consisting of a weighted lever pivoted to the valve-casing and lying approximately horizontal in both extreme positions and engaging said valve spindle and stem, said lever resting on top of said valve-stem in one extreme position with said resting-point falling between the pivot and the center of gravity of said lever, and in its opposite position with the weight-arm resting under a collar or head in said valve-stem with the pivot falling between said resting-point and said center of gravity, whereby the weight of the lever acts to hold the valve down in the first-mentioned position and up in the last-mentioned position, substantially as described.

809,262. **CONTACT DEVICE FOR INDUCTION APPARATUS.** RALPH O. HOOD, Danvers, Mass., assignor of one-half to Warren D. King, Peabody, Mass. Filed Apr. 11, 1905. Serial No. 254,981.



Claim.—1. In a contact device for induction apparatus, the combination of a casing, a flexible closure therefor forming therewith a substantially air-tight chamber and contact-points, one of which passes through the said flexible closure.

2. In a contact device for induction apparatus, the combination of a casing, a closure therefor forming therewith a substantially air-tight chamber, and contact-points one of which passes through the said closure.

3. In a contact device for sparking apparatus, the combination of a casing, a flexible closure therefor forming therewith a substantially air-tight chamber, a fixed contact-point, and a movable contact-point passing through the said flexible closure.

4. In a contact device for sparking apparatus, the combination of a casing, a flexible closure therefor forming therewith a substantially air-tight chamber, a movable contact-point passing through the said flexible closure and operatively connected therewith whereby a substantially air-tight joint between the said movable contact-point and the said closure is effected without impeding the movement of the said movable contact-point.

5. In a contact device for sparking apparatus, the combination of a casing, a flexible closure therefor forming therewith a substantially air-tight chamber, a fixed contact-point, a movable contact-point passing through the said flexible closure and adjusting means for the said fixed contact-point.

6. In a contact device for sparking apparatus, the combination of a tube closed at one end, a flexible closure for the other end thereof forming therewith a substantially air-tight chamber, a fixed contact-point and a movable contact-point passing through the said flexible closure.

286 OFFICIAL GAZETTE. JANUARY 2, 1906.

JANUARY 2, 1906. U. S. PATENT OFFICE. 287

7. In a contact device for sparking apparatus, the combination of a transparent tube closed at one end, a flexible closure for the other end thereof forming therewith a substantially air-tight chamber, a fixed contact-point and a movable contact-point passing through the said flexible closure.

8. In a device of the character specified, the combination with an induction-coil and a core therefor, of a contact device comprising a casing, a flexible closure therefor, a fixed contact-point having an armature for the said core and a movable contact-point mounted upon the said armature and passing through the said flexible closure and forming therewith a substantially air-tight joint.

809,263. SOUND-RECORD TABLET. WILLIAM H. HOYT and WILLIAM J. GAVEN, Bridgeport, Conn., assignors to The Duet Company, Hackensack, N. J., a Corporation of New Jersey. Original application filed June 11, 1904, Serial No. 212,216. Divided and this application filed June 15, 1905. Serial No. 265,266.

Claim.—1. A sound-record tablet whose body is composed mainly of earthy material and having a thin surface layer composed of like earthy materials with the addition of shellac.

2. A sound-record consisting of a tablet of suitable earthy materials containing little or no shellac but provided with a skin containing shellac and containing also resisting material similar to that of the body of the tablet, and having the sound-record in or upon said skin.

3. A sound-record consisting of a tablet having a uniform coefficient of expansion whose body is composed mainly of earthy materials containing little or no shellac and having a surface layer containing like earthy materials and shellac, said layers being united together and constituting a tablet, the sound-record groove being impressed upon said surface layer.

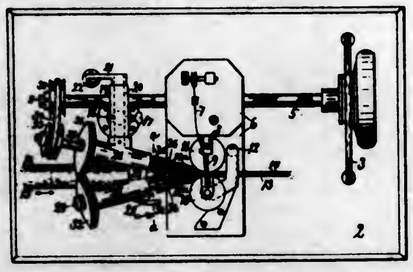
809,264. TRUSS-BRIDGE. WILLIAM J. HUMPHREYS, Elmwood, Ill. Filed Dec. 4, 1903. Serial No. 183,702.

Claim.—1. A bridge structure comprising longitudinal girders, transverse truss-beams supporting the same, standards rising from the girders, truss-beams overlying the girders, and brace-beams extending from the truss-beams in combination with couplings uniting said standards, truss-beams and brace-beams, each of said couplings comprising duplicate members arranged to abut and formed with an extended portion to receive and snugly engage one side face of each of the truss-beams, standards and brace-beams, and means for connecting the members of the coupling to each other and with said standards, truss-beams and brace-beams.

2. A bridge structure comprising longitudinal girders, transverse truss-beams supporting the same, standards rising from the girders, truss-beams overlying the girders, and brace-beams extending from the truss-beams in combination with couplings uniting said standards, truss-beams and brace-beams, each of said couplings comprising duplicate members arranged to abut and formed with an extended portion to receive and snugly engage one side face of each of the truss-beams, standards and brace-beams, each member of said coupling being formed with a semicircular recess providing when the members are assembled an opening through the coupling, a suspension-rod secured in said opening, and means for connecting the members of the coupling with each other and with said standards, truss-beams and brace-beams.

3. A bridge structure comprising a supporting-girder, transverse truss-beams underlying the same, a truss-beam above the girder, a standard intermediate the girder and truss-beam, and a brace-beam extending from said truss-beam, in combination with a coupling to unite said standard, truss-beam, and brace-beam, said coupling comprising a body portion formed with a diagonal opening, said body portion having a plurality of extensions, each of said extensions being recessed to receive and conform to the ends of the truss-beam, standard and brace-beam, a suspension-rod longitudinally adjustable in the opening in the coupling and means for securing the coupling to said truss-beam, standard and brace-beam.

809,265. FUR-SEWING-MACHINE ATTACHMENT. CHARLES B. JOHNSON, St. Paul, Minn., assignor of one-half to John W. Stiefel, St. Paul, Minn. Filed Mar. 11, 1905. Serial No. 249,596.



Claim.—1. A sewing-machine attachment comprising a pair of longitudinally grooved or corrugated rollers operatively connected with the machine and being arranged longitudinally at opposite sides of the line of feed toward the needle, and means for rotating the rollers in opposite directions.

2. A sewing-machine attachment comprising a pair of longitudinally grooved or corrugated rollers operatively connected with the machine and being arranged longitudinally at opposite sides of the line of feed toward the needle, and means for rotating the rollers in opposite directions, and an adjustable support for said rollers.

3. A sewing-machine attachment comprising a pair of longitudinally-corrugated conical rollers; an adjustable support for the rollers, means for effecting the rotation of said rollers in opposite directions, and a rod-and-lever mechanism for tilting the rollers upward, substantially as and for the purpose set forth.

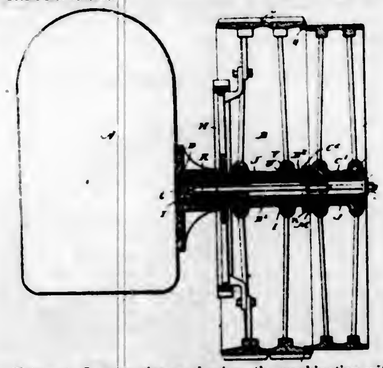
4. A sewing-machine attachment comprising a standard or support securable to the machine, a tilting head carried by the support, a pair of shafts journaled in said head and geared together to rotate in opposite directions, a pair of longitudinally-corrugated rollers extending from the ends of said shafts approximately along the line of feed toward the needle, a rocker-arm on the tilting head, a rod extending from the rocker-arm and having below the table a lever adapted to be operated by the lower limbs of the operator so as to tilt the rollers upward away from the work when so desired.

5. The combination with the feeders of a fur-sewing machine; of separators comprising longitudinally-corrugated conical rollers adapted to project between the feeders; means for supporting said rollers; and means for rotating the same in opposite directions, for the purpose set forth.

6. The combination with a fur-sewing machine, of an attachment comprising a standard securable upon the machine, a tilting frame mounted on the standard, a pair of converging shafts journaled in the frame, corrugated conical rollers fixed upon the converging ends of the shafts, two meshing gears secured one on each of said shafts, one of said shafts being operatively connected with a shaft of the sewing-machine, and means for tilting said frame and for holding it in normal position.

7. The combination with a fur-sewing machine, of an attachment comprising a standard securable upon the machine, a tilting frame mounted on the standard, a pair of converging shafts journaled in the frame, corrugated conical rollers fixed upon the converging ends of the shafts, two meshing gears secured one on each of said shafts, one of said shafts being operatively connected with a shaft of the sewing-machine, and means for tilting said frame and for holding it in normal position, and means for vertically adjusting said tilting frame, and tilting means, substantially as and for the purpose set forth.

809,266. TRACTION-WHEEL. MINARD LAFEVER, Battlecreek, Mich., and WALTER GREGORY, Minneapolis, Minn. Filed Feb. 6, 1904. Serial No. 192,365.



Claim.—1. In a traction mechanism, the combination with the engine of the two-part axle, the outer part being detachably connected to the inner part, the main drive-wheel mounted on the inner part of the axle, the power-transmitting devices interposed between the engine and the said drive-wheel, the supplemental wheel of smaller diameter than the said main wheel and mounted loosely in relation thereto on the outer part of the axle, and an abutment or series of abutments on the main drive-wheel for receiving the lateral thrust of the peripheral part of the supplemental wheel and causing said wheels to mutually brace each other.

2. In a traction mechanism, the combination with the engine, of the main drive-wheel, the power-transmitting devices interposed between the engine and the drive-wheel, the supplemental supporting-wheel of less diameter than the main wheel and mounted upon the axis thereof and rotatable about the said axis independently of the said main wheel, and an abutment or a series of abutments on the main drive-wheel for receiving the lateral thrust of the peripheral parts of the supplemental wheel, substantially as set forth.

3. In a traction mechanism, the combination with the engine, of the two-part axle, the inner part being secured to the engine and the outer part being detachably connected to the inner part, the main drive-wheel mounted on the inner part of the axle, and the supplemental wheel of smaller diameter than the main wheel and mounted loosely in relation thereto on the outer part of the axle, substantially as set forth.

4. In a traction mechanism, the combination with the engine, of the main drive-wheel, the axle therefor rigidly secured to the engine, the supplemental axle detachably secured to the main axle, and the supplemental wheel loosely mounted upon the supplemental axle, substantially as set forth.

5. In a traction mechanism, the combination with the engine, of the main axle rigidly secured to the engine and having a tubular outer end, the main drive-wheel mounted upon the main axle, the supplemental axle inserted in and detachably connected to the main axle, the supplemental wheel mounted upon the supplemental axle, and a two-part fastening device passing through the main axle and the supplemental axle, one part of said fastening device being adapted for use when the main wheel only is in position, and both parts adapted for use when both wheels are in operative position, substantially as set forth.

6. In a traction mechanism, the combination with the engine, of the bracket secured to the engine, the main tubular axle cast with the bracket, the main drive-wheel mounted on the main axle, the supplemental tubular axle inserted into the main axle, the supplemental wheel mounted loosely on the supplemental axle, and extensible devices for securing in place either the main driving-wheel when used alone or both of said wheels, substantially as set forth.

7. In a traction mechanism, the combination with the engine, of the main drive-wheel, the supplemental, loosely-mounted, supporting-wheel, the main axle rigidly connected to the engine, the supplemental axle detachably connected to the main axle, means for preventing rotation of the supplemental axle, and means for preventing lateral displacement thereof, substantially as set forth.

8. In a traction mechanism, the combination of the engine, the tubular axle rigidly connected to the engine, the main drive-wheel supported upon said axle, the supplemental tubular axle fitted within the main tubular axle, the supplemental supporting-wheel mounted upon a supplemental axle, means for locking the supplemental axle against rotation, and means for simultaneously holding the supplemental axle and the wheels against lateral displacement, substantially as set forth.

9. A wheel for a traction-engine having two rotary ground-engaging, vehicle-supporting elements mounted on a common fixed axis and independently rotatable about said axis, one element being of less diameter than the other, and the latter having an abutment or a series of abutments for receiving the lateral thrust of the peripheral parts of the former and mutually bracing the said wheels.

10. In a traction mechanism, the combination with the engine, of the main drive-wheel, the axle therefor, the supplemental axle detachably secured to the main axle, and the supplemental wheel mounted on the supplemental axle.

11. In a traction mechanism, the combination with the engine, of the main drive-wheel, the axle therefor, the supplemental axle detachably secured to the main axle, and the supplemental wheel mounted on the supplemental axle and adapted to rotate independently of the main driving-wheel.

12. In a traction mechanism, the combination with the engine, of the main axle rigidly secured to the engine and having a tubular outer end, the main drive-wheel mounted upon the main axle, the supplemental axle inserted in and detachably connected to the main axle, the supplemental wheel mounted upon the supplemental axle, and means adapted both to hold the supplemental axle in proper relation to the main axle and to hold the supplemental wheel in proper position on the supplemental axle.

13. In a traction mechanism, the combination with the engine, of the main axle, the main drive-wheel mounted upon the main axle, the supplemental axle detachably secured to the main axle, the supplemental wheel mounted upon the supplemental axle, and a two-part fastening device associated with said axles, one part of said device being adapted for use when the main wheel only is in position, and both parts being adapted for use when both wheels are in operative position.

14. In a traction mechanism, the combination with the engine, of the main drive-wheel, the supplemental supporting-wheel, the main axle, the supplemental axle detachably connected to the main axle and means for preventing rotation of the supplemental axle.

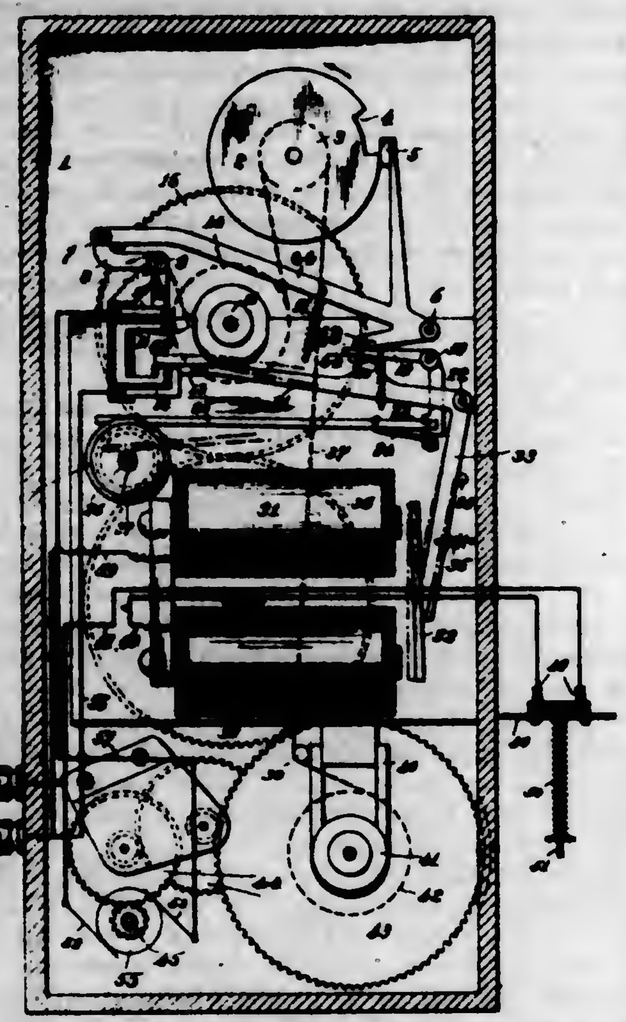
15. In a traction mechanism, the combination with the engine, of the main axle, the main drive-wheel mounted on said axle, the supplemental axle detachably connected to the main axle, the supplemental supporting-wheel mounted on said supplemental axle, and means for preventing lateral displacement of the supplemental axle relative to the main axle.

16. In a traction mechanism, the combination with the engine, of the main axle, the main drive-wheel mounted on said axle, the supplemental axle detachably connected to the main axle, the supplemental supporting-wheel mounted on said supplemental axle, and means for preventing lateral displacement both of said supplemental axle and said supplemental wheel.

809,267. STATION-INDICATOR. RICHARD F. LE BROCQ, Bloomfield, N. J., assignor of one-half to James P. Hinsman, New York, N. Y. Filed Mar. 30, 1905. Serial No. 253,890.

Claim.—1. In indicators, a casing, winding-drums in said casing carrying an indicating-strip, a stop-roll operated by said strip, a stop-disk provided with a recess mounted on said stop-roll, a spring-pressed stop-lever mounted in said casing and carrying a detent co-operating with said recess, a step-switch actuated by said stop-lever, a holding-lever adapted to engage said stop-lever and carrying a

spring-actuated latch, a worm coöperating with said latch and operating in unison with said winding-drums, a setting-lever adapted to coöperate with said holding-lever, a setting-switch actuated by said setting-lever, an electromagnet to actuate said setting-lever, an electric motor operating said winding-drums and contacts in series with said motor controlled by said stop-switch and said setting-switch and a track-switch connected in series with the electromagnet actuating said setting-lever.



2. In indicators, an indicating-strip, winding-drums connected to said strip, a stop-disk operated in unison with said strip, a stop-lever carrying a detent coöperating with said stop-disk and a stop-switch actuated by said stop-lever, a holding-lever to engage and operate said stop-lever, a latch on said holding-lever, a releasing device operating in unison with said indicating-strip and coöperating with said holding-latch, a setting-lever to engage said holding-lever, a setting-switch actuated by said setting-lever, an electromagnet coöperating with and actuating said setting-lever to be connected in series with a contact device, a motor to operate said indicating-strip, and electrical contacts governed by said stop-switch and said setting-switch controlling the operation of said motor.

3. In indicators, an indicating-strip, a stop-disk operated in unison with said strip and provided with a recess a motor to operate said strip, a stop-lever carrying a detent to coöperate with said recess, a stop-switch actuated by said stop-lever, a holding-lever to engage said stop-lever, releasing means coöperating with said holding-lever and operating in unison with said strip, a setting-lever to actuate said holding-lever and said stop-lever, a setting-switch actuated by said setting-lever, means to actuate said setting-lever and contacts governed by said setting-switch and stop-switch to control said motor.

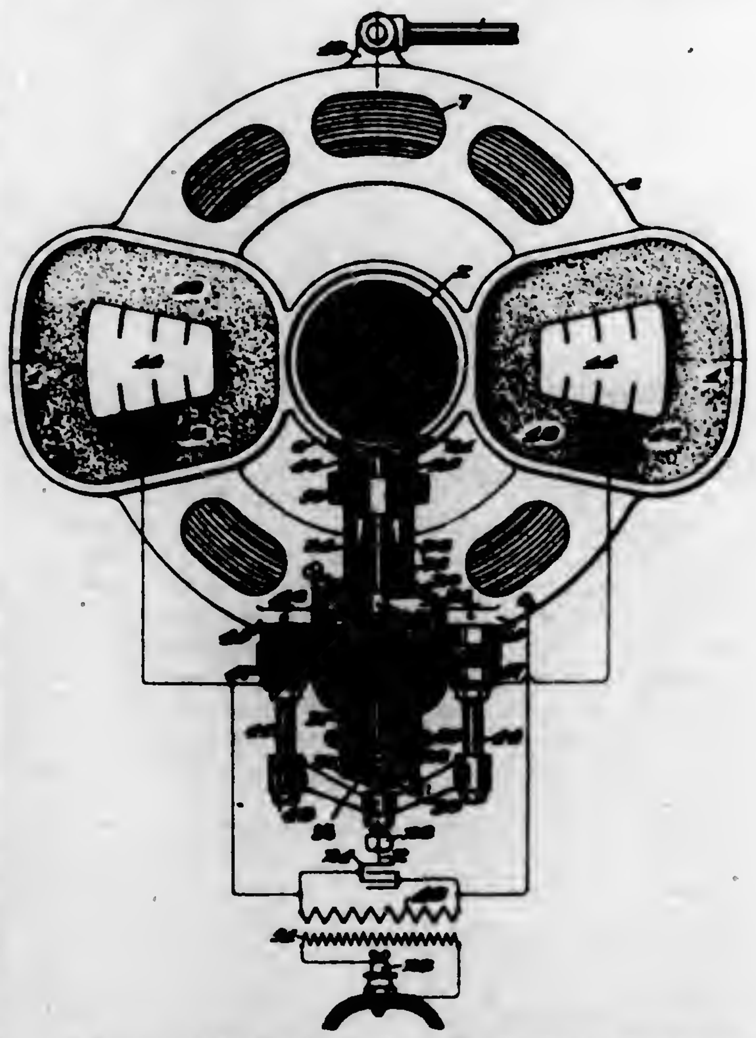
4. In indicators, indicating means, a stop-disk operated in unison with said indicating means, a stop-lever coöperating with said stop-disk, a stop-switch actuated by said stop-lever, a setting-lever to operate with said stop-lever, a setting-switch actuated by said setting-lever, means to actuate said setting-lever, means to hold said stop-lever in position after its actuation by said setting-lever until said indicating means has moved, a motor to actuate said indicating means and contacts controlling said motor and coöperating with said setting-switch and said stop-switch.

5. In indicators, indicating means, a stop operated in unison with said indicating means, a stop-lever carrying a detent coöperating with said stop, a stop-switch actuated by said stop-lever, a setting-lever to actuate said stop-lever, a setting-switch actuated by said setting-lever, means to hold said stop-lever in position after its actuation by said setting-lever until said indicating means has moved, an electric motor and electrical contacts connected in series with said motor and coöperating with said stop-switch and said setting-switch.

6. In indicators, indicating means, a stop operated in unison with said indicating means, stopping means carrying a detent to coöperate with said stop, a stop-switch actuated by said stopping means, setting means to actuate said stopping means, a setting-switch actuated by said setting means, devices to hold said stopping means in position after actuation by said setting means until said indicating means has moved, a motor to operate said indicating means and electrical contacts in series coöperating with said stop-switch and said setting-switch to control said motor.

7. In indicators, indicating means, a stop actuated in unison with said indicating means, a stop-lever carrying a detent coöperating with said stop, an electric switch actuated by said stop-lever, setting means to actuate said stop-lever, a setting-switch actuated by said setting means, a motor to operate said indicating means, and electrical contacts in series and coöperating with said stop-switch and said setting-switch to control said motor.

809,268. SPARKING IGNITION SYSTEM. Leon J. Le Pontois, New Rochelle, N. Y., assignor to Poly-Phase Ignition System Company, a Corporation of New York. Filed Nov. 17, 1904. Serial No. 233,165.



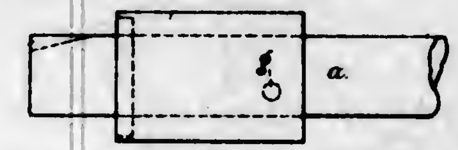
Claim.—1. A sparking ignition system comprising an alternating-current generator of the inductor type, said generator consisting of a stator having a field-magnet in the form of a permanently-magnetized ring wound from a continuous steel ribbon, symmetrically-located polar projections secured to said ring, coils wound on said polar projections, an inductor mounted on a revoluble shaft whose axis is coincident with the axis of said stator and constituting a rotor, a circuit-breaker rigidly secured to said stator, a cam mounted on the rotor-shaft and adapted to actuate said breaker at the period of maximum current generation, a transformer, sparking electrodes included in the secondary circuit of the transformer, and means for shifting said stator and breaker relative to said rotor and cam respectively so as to modify at will the time of sparking.

2. A sparking ignition system comprising an alternating-current generator of the inductor type, said generator consisting of a stator having a field-magnet in the form of a permanently-magnetized ring wound from a continuous steel ribbon, symmetrically-located polar projections secured to said ring, coils wound on said polar projections, an inductor mounted on a revoluble shaft whose axis is coincident with the axis of said stator and constituting a rotor, a circuit-breaker rigidly secured to said stator, said breaker comprising a chambered casing filled with a non-volatile electrically-conductive liquid, terminals supported in said liquid, one of said terminals being fixed in position and insulated from the casing, a movably-supported plunger to which the other terminal is secured, a cam mounted on the rotor-shaft and adapted to actuate said breaker at the period of maximum current generation, a transformer, sparking electrodes included in the secondary circuit of the transformer, and means for shifting said stator and breaker relative to said rotor and cam respectively so as to modify at will the time of sparking.

3. In an apparatus of the character described the combination with an alternating-current generator comprising a rotor and a stator, a supporting-frame for said stator, a circuit-breaker seated in an opening in said frame, a yoke carried by the frame and a clamp supported by said yoke and adapted to bear against the head of the breaker to force it to its seat.

4. In an apparatus of the character described the combination with an alternating-current generator comprising a rotor and a stator, a supporting-frame for said stator, a circuit-breaker seated in an opening in said frame, a yoke pivotally carried by said frame and a clamp supported by said yoke and adapted to bear against said breaker to force it to its seat.

809,269. COILING-MACHINE. Marcellus C. Lovejoy, Portland, Me., assignor to Edward M. Lang, Jr., Portland, Me. Original application filed Feb. 27, 1904. Serial No. 195,543. Divided and this application filed July 13, 1905. Serial No. 269,442.



Claim.—1. The combination of a shaft, a former provided with a circular opening and a circular recess in the end around said opening, means whereby said former is prevented from revolving while free to slide upon the shaft and a passage extending from end to end of said former of equal width with said circular recess, substantially as set forth.

2. The combination of a shaft, a former provided with a circular opening and also a circular recess in the end around the opening, an opening in the face of said recess connecting with a slot or passage extending to the rear end of said former and conforming in shape to the material to be treated and means whereby said former is prevented from revolving while free to slide upon said shaft, substantially as described.

3. The combination of a shaft, a former provided with a circular opening for the reception of the shaft and with a circular recess in the end thereof around said opening, an opening in the face of said recess extending diagonally rearward through said former and within the walls thereof of equal width and of a shape conforming to the material to be treated, substantially as described.

809,270. TOY. Isaac N. Phipps, Mount Sterling, Ky. Filed Nov. 14, 1904. Serial No. 232,866.

Claim.—1. A toy comprising a member provided with an opening, a spring within said opening whose one end is secured to said member, the free end of said spring extending beneath said member, a second member provided with studs or protrusions adapted to engage the free end of said spring, a portion of said second member adapted to take into the opening in said first member and through the spring therein, mechanism secured to said first member, said second member provided with a second stud or protrusion adapted to engage with said mechanism on the first member, means secured to said first member and engaging with said mechanism whereby said mechanism is disengaged from the second stud or protrusion and the second member released and subjected to the action of the spring, substantially in the manner shown and for the purpose described.

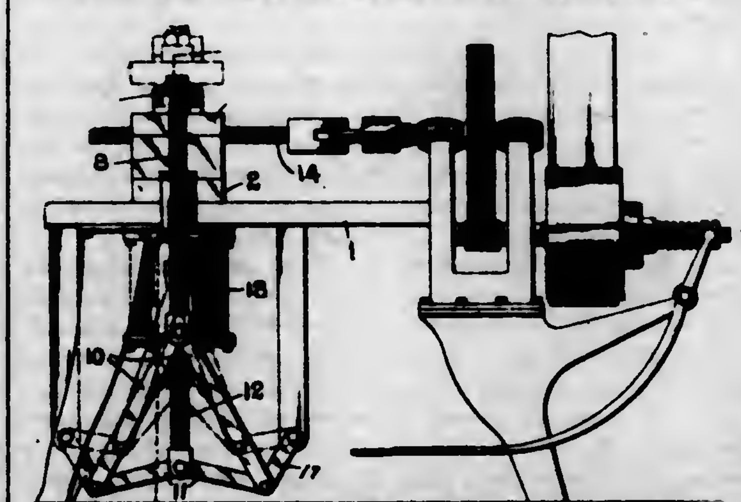
2. A toy comprising a member having an opening therein, a coil-spring secured within said opening, the free end of said spring extending beneath said member, a second member, two sets of studs or protrusions on the upper face of said second member, the second member provided with a spindle portion adapted to take through the opening in the first member, the free end of the said spring adapted to engage with one set of said studs or protrusions, a spring-controlled lever secured to said first member and adapted to engage with the other set of said studs or protrusions, and a trigger adapted to engage with said spring-controlled lever whereby the latter may be disengaged from the stud or protrusion on said second member, and the latter subjected to the action of the spring, substantially as shown and for the purpose described.

3. A toy comprising a member having an opening therein, a coil-spring within said opening, one end of which is secured to said member and its free end extending slightly outside of said opening, a second member provided with a stud or studs on its upper surface, said second member adapted to take into the opening in said first member and adapted to be engaged by the free end of said spring, spring-controlled mechanism on said first member and adapted to engage with said second member to retain it in the desired position, and means secured to said first member for releasing said spring-controlled mechanism from the second member, whereupon the latter is subjected to the action of the spring, substantially as shown and for the purpose described.

4. A toy comprising a member having an opening therethrough, a coil-spring within said opening, one end of which is secured to said member, while the other end terminates in a hook, a second member provided with studs or protrusions on its upper surface, said second member provided with a spindle adapted to take through the opening in said first member and inside of the coil-spring, said studs or protrusions being in line with the hook end of the said spring and adapted to engage therewith, mechanism pivotally secured to said first member and adapted to engage with said second member and retain it at the desired point, and means pivotally secured to said first member, and adapted to engage said mechanism to release the second member and subject it to the action of the spring, substantially in the manner and for the purpose described.

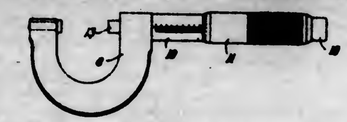
5. A toy comprising a member having an opening therethrough, a coil-spring within said opening, whose one end is secured to said member and the other terminating in a hook, a second member provided with studs or protrusions on its upper surface in line with the hook end of said spring, said second member also provided with a stud or studs at a different distance from the center from the first-mentioned stud or studs, a spring-controlled mechanism pivotally secured to said first member and adapted to engage with the last-mentioned stud or studs, and means secured to said first member and adapted to engage with said mechanism to release it from engagement with the stud or studs whereupon the second member is subjected to the action of the spring, substantially as shown and in the manner described.

809,271. VISE. Francis M. Stambaugh, St. Louis, Mo., assignor to The American Brake Company, St. Louis, Mo., a Corporation of Missouri. Original application filed Mar. 7, 1905, Serial No. 248,849. Divided and this application filed May 15, 1905. Serial No. 260,477.



Claim.—In a metal-working machine, a base carrying a rigid jaw provided with a facing of soft metal, a coöperating jaw faced with soft metal and carried by a movable cross-head, a plurality of pitmen connected to said cross-head and moving in guideways formed in the base, toggle-levers connected to the lower end of each pitman, a cylinder carried by said base, a fluid-actuated piston mounted in said cylinder for moving the cross-head to clamp the jaws together and provided with a piston-rod, compound toggle-levers joined to the toggle-levers on the pitmen and connected at their respective ends to the piston-rod and to stationary parts of the base, and means for moving the piston to disengage the clamping-jaws; substantially as described.

809,272. QUICK-ADJUSTING MICROMETER. LARET S. STARRETT and JOHN A. ASHLL, Athol, Mass., assignors to The L. S. Starrett Company, Athol, Mass., a Corporation of Massachusetts. Filed May 26, 1905. Serial No. 262,388.



Claim.—1. A micrometer-gage comprising a frame or body, a self-opening split nut, a micrometer-screw extending through said nut, and means for automatically compressing said nut to engage it with the screw, and for manually releasing the nut-prongs from such compression and engagement, by direct endwise pressure applied axially, for the purpose set forth.

2. A micrometer-gage, comprising a frame or body, a self-opening split nut, a micrometer-screw extending through said nut, and means for automatically compressing said nut to engage it with the screw, and for manually releasing the nut-prongs from such compression and engagement, to permit free reciprocation, the surfaces of the frame, fixed barrel and rotary sleeve being symmetrical and free from any apparent adjusting devices, substantially as set forth.

3. A micrometer comprising a frame or body and a spindle and rotatable sleeve secured to each other and to parts having a threaded engagement with a fixed part of the instrument, in combination with means for interrupting such threaded engagement and for imparting a free sliding movement to said spindle and sleeve with relation to the frame and parts fixed thereon, and with an inclosed terminal catch limiting such sliding movement and preventing accidental dismemberment, for the purpose set forth.

4. A micrometer comprising a frame or body and parts fixed thereon including a long hollow screw, in combination with a spindle within said screw, a rotatable sleeve concentric therewith and an intermediate threaded part adapted to engage the threads of said screw for adjustment by rotation, and with means for interrupting such threaded engagement and imparting a sliding movement to said spindle and sleeve, and a concealed stop device adapted to engage a recess within said sleeve to properly limit such sliding movement, for the purpose set forth.

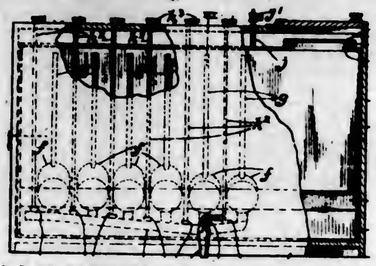
5. A quick-adjusting micrometer, comprising four rigid parts connected together, and consisting of the frame or body at one end of the instrument, an integral tubular extension thereof, a longitudinally-graduated cylindrical barrel and an inclosed hollow screw, in combination with four movable parts united together at the other end of the instrument and comprising the axial spindle, the inclosing rotatable sleeve, the intermediate split nut surrounding said screw and an actuating-collar for said nut, these four parts adapted for adjustment by rotation under threaded engagement and for quick, sliding adjustment when threads are disengaged, substantially as set forth.

6. A quick-adjusting micrometer comprising the frame or body, the graduated cylindrical barrel fixed thereon, and the elongated hollow screw projecting rigidly from the frame, in combination with the axial spindle within said screw, the rotatable sleeve, the intermediate split nut surrounding said screw and the adjustable nut-actuating collar with terminal head and spring, serving to disengage and reengage said nut and screw, substantially as set forth.

7. The improved micrometer described, embodying the frame 8, the hollow screw 12 projecting rigidly therefrom, and the rigid, longitudinally-graduated, cylindrical barrel 10 concentric therewith, in combination with the axial spindle 13, the shouldered terminal cap 16 fixed thereon, the outer rotatable sleeve secured to the periphery of said cap and the split nut 14 held by its tubular end upon a reduced shoulder of said cap, and with the nut-collar 17 having extensions 18 projecting through recesses in said cap and connected to the head 19, for the purpose set forth.

809,273. LIQUID-MEASURING DEVICE. FRANK S. TURNER, SUMNER FRANK, and WARD B. MARTIN, Genoa, Ohio, assignors, by mesne assignments, to W. B. Martin. Filed July 13, 1903. Serial No. 165,902.

Claim.—1. In a liquid-measuring device, the combination, with a liquid-supply reservoir, of a pipe communicating at one end with the liquid-receiving interior space of the reservoir, and contained within the reservoir, which pipe is provided with a valved discharge branch between the ends of the pipe and declines toward its said branch from both ends; a row of measuring vessels contained within the reservoir along the pipe and communicating with the passage-way formed by and interiorly of the said pipe, and the valves arranged to control continuity in the said passage-way, substantially as and for the purpose set forth.



2. In a liquid-measuring device, the combination, with a liquid-supply reservoir, of a pipe arranged within the liquid-receiving interior space at the bottom and forward side of the reservoir and communicating at one end with the said space, which pipe is provided with a valved discharge branch between the ends of the pipe, and declines toward its said branch from both ends; a row of measuring vessels contained within the reservoir along the aforesaid pipe and having bottoms declining toward the pipe, which vessels communicate at the lower end of the said bottoms with the passage-way formed by and interiorly of the said pipe, and the valves arranged to control continuity in the said passage-way, substantially as and for the purpose set forth.

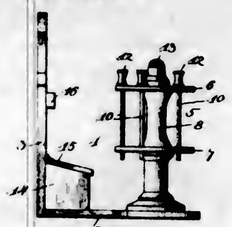
3. In a liquid-measuring device, the combination, with a liquid-supply reservoir of a row of vented measuring vessels within the lower portion of the reservoir, which row is arranged widthwise of the reservoir; a pipe arranged at the bottom and longitudinally of the row of measuring vessels and provided with a valved discharge branch extending outside of the reservoir, which pipe is contained within the liquid-receiving interior space of the reservoir and communicates with the interior chambers of the aforesaid vessels, and normally open valves arranged to control continuity in the passage-way formed by and within the said pipe, substantially as and for the purpose set forth.

4. In a liquid-measuring device, the combination, with a liquid-supply reservoir, of a row of vented measuring vessels contained within the lower portion of the liquid-receiving interior space of the reservoir, which vessels have their bottoms declining toward the front of the reservoir and have outlets at the lower ends of the said bottom; a pipe arranged within the liquid-receiving interior space of the reservoir and extending longitudinally of the aforesaid row of vessels, which pipe is provided with a valved discharge branch extending outside of the said space and communicates with the aforesaid outlets, normally open valves arranged to control continuity in the passage-way formed by and within the said pipe and arranged as required to render any one or more of the aforesaid vessels drainable through the said pipe and the connected branch without moving or interfering with the contents of the remaining vessel or vessels, and means for manipulating the said valves from the exterior of the reservoir.

5. In a liquid-measuring device, the combination, with a liquid-supply reservoir having a declining bottom and a trough arranged at the lower end of the said bottom and in open relation with the chamber of the reservoir, of a plurality of vented measuring vessels arranged over the said bottom and contained within the chamber of the reservoir, a pipe arranged within and longitudinally of the said trough and provided with a valved discharge branch extending outside of the said trough, which pipe is in open relation with the chambers of the said vessels, the said normally open valves arranged to control continuity in the passage-ways formed by and within the said pipe, substantially as and for the purpose set forth.

6. In a liquid-measuring device, the combination, with a liquid-supply reservoir having a declining bottom and a trough arranged at the lower end of the said bottom and in open relation with the chamber of the reservoir, of a row of vented measuring vessels arranged over the said bottom and contained within the chamber of the reservoir; a pipe arranged within and longitudinally of the said trough and provided with a valved discharge branch which extends outside of the said trough and having upwardly-projecting tubular members which connect at their lower ends with the passage-way formed within and extending longitudinally of the said pipe and communicate, at the upper end, with the chamber of the different measuring vessels, respectively, which pipe has one of the said upwardly-projecting members forming one end of the said pipe and is open at its opposite end; normally open valves arranged to control continuity in the aforesaid passage-way between the measuring vessels, and another normally open valve arranged to control continuity in the said passage-way between the open extremity of the pipe and the adjacent side of the adjacent measuring vessel.

809,274. SPOOL-CABINET. JOHN A. EPLEY, Iuka, Kans. Filed Apr. 24, 1906. Serial No. 257,944.



Claim.—The herein-described spool-cabinet consisting of a base 2, an upright back 3 secured to said base and provided near its upper end with an opening 18, whereby said cabinet may be suspended from a wall or other support, a box 14 secured at the juncture of said base and back and provided with a cover 15 hinged to the back 3, a rack 16 projecting from and secured to the back and provided with openings 17 for supporting scissors and other implements, in upright position against the back 3, a spool-rack comprising a pair of horizontally-disposed disks 6, 7 connected together by a centrally-disposed sleeve 8, a standard 4, consisting of a rod passing through said disks and sleeve and supported upon the base 2, an annular series of removable spool-receiving spindles 10 provided with heads 12, said spindles passing through the disks 6, 7 to retain spools thereon, and a removable needle-cushion 13 arranged on the upper end of the standard 4, essentially as described.

809,275. SPIRIT-LEVEL. CALVIN S. BROWN, Toledo, Ohio, and JOSEPH N. CLOUSE, St. Louis, Mo. Filed Jan. 14, 1904. Renewed Dec. 1, 1905. Serial No. 290,331.

Claim.—1. In a spirit-level movement fitted to and secured in the mortise in the wooden beam, the combination of the bed-frame F to which is pivoted the various working parts consisting of the gear-segment G with its tube H and spirit-vial I and double index-finger N also the shaft J with its worm-gear K, thumb-nut L spring f^3 and compression lock-plate M with its nut m', spring m^3, and hook m^4, all working together to operate the spirit-vial I and the double index-finger N, substantially as shown and described.

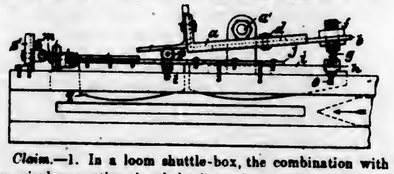
2. In a spirit-level movement for the purpose of obtaining inclines from the level in degrees or in fractions of inches and deflections from a vertical line in the plumb in degrees or in fractions of inches, the scale segment-plate f^4 provided with a double scale in combination with the double index-finger N, the gear-segment G, the spirit-vial I, and its tube H, and the operating-shaft J with its worm-gear K, spring f^3 and thumb-nut L, substantially as shown and described.

3. In a spirit-level movement the works provided with a bed-plate secured to the beam in its mortise the said works consisting of the gear-segment G, provided with the spirit-vial I and tube H, the worm-gear K with its shaft J provided with spring f^3 nut f' and squared portion f^2 and the thumb-nut L with its flange f' sliding on the said squared portion f^2, also the compression lock-plate M, with its stop-nut m', coiled spring m^3 and yoke-hook m^4, said thumb-nut L and stop-nut m' extending to the surface of the beam forms a means of operating the gear-segment G, with its parts attached, substantially as shown and described.

4. In a spirit-level, the general combination of the wooden beam with its mortises, the perforated metal plates with glass plates back of them covering the said mortises, the movements secured in the said mortises consisting of the bed-frame having a double scale segment-plate, the gear-segment plate pivoted to the said bed-frame and mounted with the tube and spirit-vial, the adjustable double index-finger secured to the said gear-segment, the worm-gear, coiled spring, and thumb-nut for operating said segment-gear, the compression lock-plate with its stop-nut coiled spring and yoke-hook holding said thumb-nut in compressed position, substantially as shown and specified.

REISSUES.

12,428. SHUTTLE-BRAKE. JEAN LAFORET, Etoile, France, assignor to Albert B. Strange, New York, N. Y. Filed Dec. 21, 1904. Serial No. 237,867. Original No. 763,643, dated June 14, 1904.



Claim.—1. In a loom shuttle-box, the combination with two successively-operative shuttle-brakes, of an oscillatory beam bearing at its ends respectively against the one and other of said brakes for the purpose set forth.

2. In a loom shuttle-box, the combination with two successively-operative pivoted shuttle-brakes, of an oscillatory beam having adjustable bearing at its ends respectively against the one and other of said brakes for the purpose set forth.

3. In a loom shuttle-box, the combination with two successively-operative shuttle-brakes, of an oscillatory beam bearing at one end positively against the rearmost brake and at the other end resiliently against the foremost brake for the purpose set forth.

4. In a loom shuttle-box, the combination with two successively-operative shuttle-brakes, of an oscillatory beam adjustable in length and having horizontally-adjustable ends bearing respectively against the one and other of said brakes for the purpose set forth.

5. In a loom, the combination, with the batten or lay structure and with the shuttle, of two successively-operative shuttle-brakes, and an oscillatory beam adapted to bear at its ends respectively against the one and the other of said brakes, said shuttle-brakes being spaced a distance corresponding to the length of the shuttle whereby to bear against both end portions thereof when the shuttle is completely boxed, substantially as described.

6. In a loom, the combination, with the batten or lay structure and with the shuttle, of two successively-operative shuttle-brakes, and an oscillatory beam adapted to bear at its ends respectively against the one and the other of said brakes and against one of them resiliently, said shuttle-brakes being spaced a distance corresponding to the length of the shuttle whereby to bear against both end portions thereof when the shuttle is completely boxed, substantially as described.

12,429. WELT-MAKING MACHINE. GEORGE H. ROLLINS, East Bridgewater, Mass. Filed July 12, 1905. Serial No. 269,417. Original No. 743,794, dated Jan. 5, 1904.

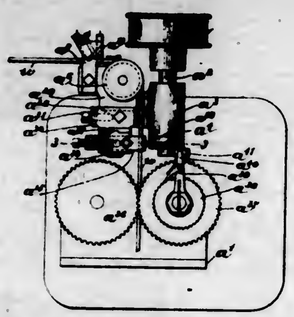
Claim.—1. A machine of the kind described, comprising means for feeding a welt-strip, means for holding said welt-strip, means cooperating therewith for making a transverse cut in one face of said strip, and means for limiting the length of the transverse cut in the strip to fall short of the outer edge of the strip.

2. A machine of the kind described, comprising means for feeding a welt-strip, and automatic cutting mechanism for making a series of transverse cuts in one side of said welt, less in depth than the thickness of the welt and stopping short of the outer edge of the strip.

3. A machine of the kind described, comprising means for feeding a welt-strip, a holder for the strip, and cutting mechanism for removing the leather therefrom to form a series of grooves within and extending transversely of one face of said strip, and means for rocking said holder for controlling the length of the groove with relation to the width of the strip.

4. In a machine of the kind described, a holder for a welt-strip

4. In a machine of the kind described, a holder for a welt-strip, a cutter coöperating therewith for cutting said strip, said holder having a passage conforming in shape and size to the welt-strip and substantially embracing the strip, said passage being adjustable for different thicknesses of strips.



5. In a machine of the kind described, a holder for a welt-strip, a cutter coöperating therewith for removing transverse grooves of material from one face of said strip less in length than the width of the strip, and means for varying the depth of the grooves formed.

6. In a machine of the kind described, a holder for a welt-strip, a cutter having a blade acting intermittently on and transversely cutting said strip on one side at intervals of its length, and means for varying the angular position of said holder with relation to said cutter to change the length of the cuts.

7. In a machine of the kind described, a holder for a welt-strip, a cutter coöperating therewith for cutting said strip, said holder substantially embracing the strip, and means for varying the angular position of said holder with relation to said cutter.

8. In a machine of the kind described, a holder for a welt-strip, a cutter coöperating therewith for cutting said strip, said holder containing means for bending said welt-strip transversely to its length.

9. In a machine of the kind described, a holder for a welt-strip, a cutter coöperating therewith for cutting said strip, said holder being adjustable for different thicknesses of strips, and also adjustable toward and from said cutter.

10. A machine of the kind described, comprising a cutter, for cutting a welt-strip and means for bending said strip opposite said cutter in a direction transverse to its length.

11. In a machine of the kind described, a holder for a welt-strip comprising opposite parts for substantially embracing said strip, one of said parts having a deflecting device for engaging the welt on one side and bending the adjacent edge thereof but of line with the rest of the welt.

12. In a machine of the kind described, a holder for a welt-strip comprising two parts and means for adjusting the same toward and from each other for different thicknesses of strips, one part having a slotted portion for engaging the outer side of the welt, and a cutter for operating in said slot on said welt.

13. In a machine of the kind described, means for holding a welt-strip comprising a carrier, means for adjusting the same out and in, and a holder vertically adjustable on said carrier, said holder having an opening for the passage of the welt-strip.

14. A machine of the kind described, comprising a holder for a welt-strip, a cutter coöperating therewith for cutting transverse notches therein, and feeding mechanism for feeding the welt-strip, including a feed device having projections spaced apart to correspond with the notches cut in the strip, said projections entering said notches and feeding the strip thereby.

15. A machine of the kind described, comprising feeding mechanism, a cutter for making a series of transverse cuts in a welt-strip, cutting mechanism for longitudinally cutting said strip, and directing means for presenting said strip in different directions to said respective cutting devices.

16. In a machine of the kind described, a holder for a welt-strip, a cutter coöperating therewith for making transverse cuts in one face of said strip, and means for varying the length of the cuts.

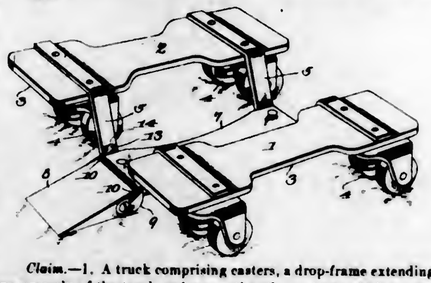
17. In a machine of the kind described, a holder for a welt-strip, a cutter coöperating therewith for making transverse cuts in one face of said strip, and means for varying the location of said cuts toward and from the edge of said strip.

18. A machine of the kind described, comprising means for cutting a longitudinal groove in a welt-strip, and means for cutting a series of transverse cuts intersecting said longitudinal groove.

19. A machine of the kind described, comprising means for feeding a welt-strip, and means for longitudinally grooving said welt-strip, combined with automatic cutting means for simultaneously cutting transversely into the welt partially through from one side thereof.

20. A machine of the kind described, comprising means for feeding a welt-strip, and three coöperating cutters for simultaneously cutting respectively a longitudinal groove, a beveled edge, and a series of transverse cuts stopping short of the outer edge of the welt.

12,430. **TRUCK.** HERMAN WEBER, Colorado Springs, Colo. Filed May 26, 1905. Serial No. 262,508. Original No. 772,014, dated Oct. 11, 1904.



Claim.—1. A truck comprising casters, a drop-frame extending transversely of the truck and connecting the casters, said frame being permanently secured to and serving to maintain the casters in fixed relative positions, and a fixed load-receiving platform supported by said drop-frame.

2. A truck comprising casters, a load-receiving platform between them, a loading member extending from one end of the platform proper to a point beyond the casters, and a drop frame connecting the casters and serving as a support for such platform.

3. A truck comprising casters, and a load-receiving platform arranged between and supported by the casters, there being a loading member extending from the receiving end of the platform to a point beyond the line of the casters, the platform having a dished load-receiving surface disposed approximately in the horizontal plane of the revoluble elements of the casters.

4. A truck comprising wheeled bolsters, drop frame-bars connecting the bolsters, and a load-supporting platform carried by the bars between the bolsters.

5. A truck comprising a pair of wheeled bolsters, drop frame-bars connecting the bolsters, a load-supporting platform carried by the bars, and a skid coacting with the platform.

6. A truck comprising a pair of wheeled bolsters, drop frame-bars connecting the bolsters, a dished load-supporting platform carried by the frame-bars, and a skid pivotally connected with one of the frame-bars.

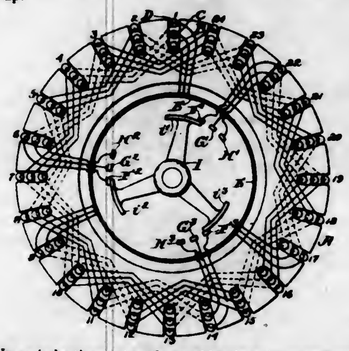
7. A truck comprising a pair of wheeled bolsters, drop frame-bars connecting the bolsters, a dished load-supporting platform carried by the frame-bars, and a wedge-shaped skid pivotally connected with one of the frame-bars.

8. A truck comprising a pair of bolsters, caster-wheels combined therewith, drop frame-bars connecting the bolsters, a dished load-supporting platform carried by the frame-bars, and a wedge-shaped skid connected with one of the frame-bars and provided on its under side with spurs.

12,431. **INDUCTION-MOTOR.** ARE L. CUSHMAN, Concord, N. H., assignor, by direct and mesne assignments, to The Cushman Electric Company, Concord, N. H., a Corporation of Maine. Filed Nov. 19, 1904. Serial No. 233,541. Original No. 726,234, dated Apr. 14, 1903.

Claim.—1. In an induction-motor, a secondary member provided with a secondary winding having a plurality of elements arranged in multiple arc, all adapted to carry currents in one direction only, any desired number of which may be used at the same time, and each of which when in use acts as an effective element of the winding contributing to the polarization of the secondary member, and means carried by the secondary member for bringing said elements one at a time into action and for removing them from action, said means admitting the current fully to each element as such element is brought into action.

2. In an induction-motor, the combination of a secondary winding made up of elements of low specific resistance, and means for forming a closed induced circuit from a part only of said elements so as to reduce the current induced in said secondary at starting, and means for bringing into action additional elements as the motor speeds up.



3. In an induction-motor, the combination of a secondary winding made up of elements of low specific resistance, means for forming a closed circuit from part of said elements, and means for forming additional closed circuits from other elements as the motor speeds up.

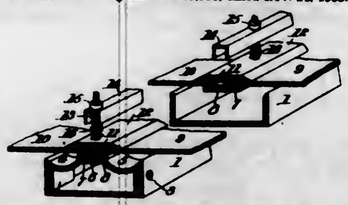
4. In an induction-motor, the combination of a secondary winding made up of elements of low specific resistance, means for forming a closed circuit from a part of said elements and means for forming additional closed circuits in multiple arc therewith from other elements as the motor speeds up.

5. In an induction-motor, the combination of a plurality of elements part of which form star-connected closed circuits and means for connecting others of said elements to form additional star-connected closed circuits and disconnecting them as desired.

6. In an induction-motor, the combination of a plurality of elements part of which are connected in closed circuit star fashion and means for connecting others of said elements in closed circuits star fashion and in multiple arc with said first star-connected elements.

7. In an induction-motor, the combination of a winding made up of a plurality of elements of low specific resistance, a switch for gradually bringing said elements into and removing them from action, and means for operating said switch.

12,432. **SKYLIGHT.** JOHANNES DREKHARDT, Berlin, Germany, assignor to William F. Pfaus, New York, N. Y. Filed Oct. 14, 1905. Serial No. 282,969. Original No. 745,310, dated Nov. 24, 1903.



Claim.—1. A roof structure comprising supporting-bars, means carried thereby for supporting the adjacent edges of glass panes, uprights extending from said bars between the panes, and bars supported by said uprights above the panes and parallel with the supporting-bars.

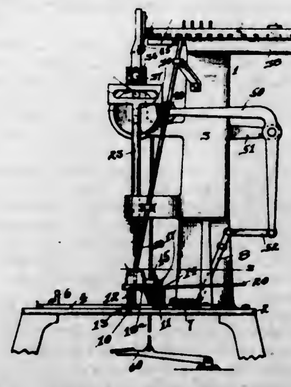
2. A roof structure comprising supporting-bars, brackets supported by these bars at a suitable distance from each other, vertical bolts projecting from these brackets, flat iron bars connecting the brackets of one bar with each other, elastic strips on said iron bars serving as supports for the edges of the panes of glass, elastic strips covering the adjacent edges of the panes of glass, protecting-caps covering said elastic strips, springs for pressing said caps and consequently the edges of the panes of glass firmly on their seats, and bars resting on set-offs on the upper ends of the bolts running parallel to the supporting-bars substantially as described and shown and for the purpose set forth.

3. Improved bars used for the support of panes of glass constituting the roofs of greenhouses and other glass-covered buildings, comprising in combination supporting-bars, brackets supported by these bars at a suitable distance from each other, vertical bolts projecting from these brackets, flat iron bars connecting the brackets of one bar with each other, elastic strips on said iron bars serving as supports for the edges of the panes of glass, elastic strips covering the adjacent edges of the panes of glass, protecting-caps covering said elastic strips, spiral springs coiled around the vertical bolts pressing said caps and consequently the edges of the panes of glass firmly on their seats, and bars resting on set-offs on the upper ends of the bolts running parallel to the supporting-bars substantially as described and shown and for the purpose set forth.

4. Improved bars used for the support of panes of glass constituting the roofs of greenhouses and other glass-covered buildings, comprising in combination U-shaped iron bars, ⊓-shaped brackets inserted into these bars at a suitable distance from each other, two grooves in the upper surface of said brackets forming bridges between them, vertical bolts screwed into these bridges, flat iron bars connecting the bridges of one bar with each other, felt strips on said iron bars serving as supports for the edges of the panes of glass, felt strips covering the adjacent edges of the panes of glass, protecting-caps covering said felt strips, spiral springs coiled around the vertical bolts pressing said caps and consequently the edges of the panes of glass firmly on their seats, and ⊓-shaped iron bars resting on set-offs on the upper ends of the bolts running parallel to the supporting-bars, substantially as described and shown and for the purpose set forth.

5. A roof structure comprising channel-shaped supporting-bars, brackets having their ends turned down and fitted within the sides of the channel-shaped bars, said brackets being secured to the said bars, means for supporting the adjacent edges of glass panes, uprights extending between the panes, and bars supported by said uprights above the panes and parallel with the supporting-bars.

12,433. **HEEL-BUILDING MACHINE.** WILLIAM WOLFE, Batavia, Ohio, assignor to The American Heel Machine Company, Cincinnati, Ohio, a Corporation of Ohio. Filed May 29, 1905. Serial No. 262,948. Original No. 760,768, dated May 24, 1904.



Claim.—1. In a heel-building machine, a plurality of sectional and independently-adjustable plates for engagement with the edges of heel-lifts, and a carrier for receiving and moving the heel-lifts into engagement with said adjusting-plates, substantially as described.

2. In a heel-building machine, a plurality of independently-adjustable plates adapted to adjust a pile of heel-lifts, a carrier for supporting the lifts, and a gage carried by the carrier and serving in connection with the latter to force the lifts into engagement with the plates, substantially as described.

3. In a heel-building machine, a plurality of independently-adjustable plates adapted to adjust a pile of heel-lifts, a carrier for the compilation of heel-lifts, a gage on the carrier serving in connection with the plates to engage the heel-lifts and form the heel-blank, means for reciprocating the carrier, and means for cushioning said movement, substantially as described.

4. In a heel-building machine, a bed-plate having guides, a car-

rier engaging said guides, a pair of sectional and independently-adjustable heel-lift-adjusting devices carried by the bed-plate and extending over the carrier, a third heel-lift-adjusting device carried by the bed-plate and held in position for engagement by the rear edge of the heel-blank, and means for moving the carrier to move the taps or lifts into engagement with the said adjusting devices, substantially as described.

5. In a machine of the class described, a bed adjusting devices on the bed, a perforated nailing-block for engaging over the top of the blanks, means for feeding nails to the perforations, a nail-driver, an actuating-shaft, connections between the shaft and driver, a blank-supporting carrier, and connections between said driving-shaft and carrier for moving the latter into position for the nail-driving operation, substantially as described.

6. In a heel-building machine, a bed, heel-lift-adjusting devices on said bed, a heel-blank carrier, a perforated nail-block carrier, a nail-driver, a driving-shaft, connections between the said shaft and the nail-driver, connections between the said shaft and the carrier adapted to actuate said members in time movements, and means for intermittingly operating the said shaft, substantially as described.

7. In a heel-building machine, a bed having a slideway, a heel-lift carrier adapted to be reciprocated in said slideway, devices for adjusting the edges of the heel-lifts located on the bed at the inner end of the slideway, a device on the carrier for adjusting the edges of the heel-lifts, and a nailing mechanism supported upon the bed over the inner end of said slideway.

8. In a heel-building machine, a bed having a slideway, a heel-lift carrier adapted to be reciprocated in said slideway, adjusting devices on the bed at the inner end of the slideway, adapted to engage the curved edges of the lifts when presented by the carrier, a device on the carrier for adjusting the straight edges of the lifts, and a nailing mechanism supported on the bed over the inner end of said slideway and between the stationary adjusting devices.

9. In a heel-building machine, a bed having a slideway, a heel-lift carrier adapted to be reciprocated in said slideway, devices for adjusting the edges of the heel-lifts located on the bed at the inner end of the slideway, a coöperating device on the carrier for adjusting the edges of the heel-lifts, a nailing mechanism supported upon the bed over the inner end of said slideway, and power-driven means for automatically actuating the driving mechanism and the sliding carrier, substantially as described.

10. In a machine of the class described, a bed, a nail-block over the bed, a carrier on the bed movable to and from position under the nail-block, devices located on the carrier and on the bed for engaging and adjusting the heel-lifts on the carrier, and power-driven means for driving a nail from the nail-block through the heel-lifts, and for moving the carrier into position for the nail-driving operation, substantially as described.

11. In a machine of the class described, a bed, a nail-block over the bed, a carrier on the bed moveble to and from position under the nail-block, a gage on the carrier for engaging the front edges of the heel-lifts, adjusting devices on the bed around the carrier for engaging the rear and side edges of the heel-lifts, and power-driven means for driving a nail from the nail-block through the lifts and for moving the carrier into position for the nail-driving operation, substantially as described.

12. In a heel-building machine, a bed, a carrier for supporting the heel-lifts, a nail block and driver for engaging the top of the lifts, adjusting and gage devices for engaging the edges of the lifts, driving mechanism and connections adapted to move the carrier to bring the compiled lifts into engagement with the adjusting devices under the nailing-block and to operate the driver, substantially as described.

13. In a heel-building machine, a bed, a carrier for supporting the heel-lifts, a nail block and driver for engaging the top of the lifts, adjusting and gage devices for engaging the edges of the lifts, a driving-shaft, connections between said driving-shaft, the nail driver and carrier adapted to move the carrier on the bed to engage the lifts with the adjusting devices under the nail-block, to drive a nail, and means for intermittingly operating said shaft, substantially as described.

DESIGNS.

37,766. FINGER-RING. JOSEPH LEWIS HERZOG, New York, N. Y. Filed Dec. 4, 1905. Serial No. 290,515. Term of patent 7 years.

37,766.

Claim.—The ornamental design for a ring as shown.

Claim.—The ornamental design for a belt, as shown.

TRADE-MARKS

PUBLISHED JANUARY 2, 1906.

The following trade-marks have been adjudged entitled to registration under the act of February 20, 1905, and are published in compliance with section 6 of said act. Said section provides:

"Any person who believes he would be damaged by the registration of a mark may oppose the same by filing notice of opposition, stating the grounds therefor, in the Patent Office within thirty days after the publication of the mark sought to be registered, which said notice of opposition shall be verified by the person filing the same before one of the officers mentioned in section two of this act. If no notice of opposition is filed within said time the Commissioner shall issue a certificate of registration therefor, as hereinafter provided for."

Marks which are stated to have been "Used ten years" are registrable under the last proviso of section 5 of said act, which is as follows:

"And provided further, That nothing herein shall prevent the registration of any mark used by the applicant or his predecessors, or by those from whom title to the mark is derived, in commerce with foreign nations or among the several States, or with Indian tribes, which was in actual and exclusive use as a trade-mark of the applicant or his predecessors from whom he derived title for ten years next preceding the passage of this act."

Section 14 of said act provides for the following fee:

"On filing notice of opposition to the registration of a trade-mark, ten dollars."

DECISIONS

OF THE

COMMISSIONER OF PATENTS

AND OF

UNITED STATES COURTS IN PATENT CASES.

COMMISSIONER'S DECISIONS.

NETH AND TAMPLIN *v.* OHMER.

Decided October 24, 1905.

INTERFERENCE—JUDGMENT ON THE RECORD.

Where the preliminary statement of N. and T. failed to overcome the record date of O.'s application and motion by N. and T. to amend their preliminary statement had been denied and the denial affirmed on appeal, *Held* that O. is entitled to an award of priority of invention.

APPEAL from Examiners-in-Chief.

FARE-REGISTER.

Mr. Richard J. McCarty and *Mr. D. P. Wolhaupter* for Neth and Tamplin.

Mr. Harry A. Toulmin for Ohmer.

ALLEN, *Commissioner:*

This is an appeal by Neth and Tamplin from a decision of the Examiners-in-Chief affirming the decision of the Examiner of Interferences awarding priority of invention to Ohmer as to the following issue:

1. A fare-register comprising a series of independent counters for counting separate classes of fares, an actuating device for each counter, an operating-slide common to said actuating devices, and a series of setting-cams, one for each actuating device, each of said cams when set moving its proper actuating device into operative relation with said common operating-slide.

2. A fare-register comprising a series of independent counters for counting separate classes of fares, setting-cams, one for each counter, connected link-and-lever mechanism between each cam and its appropriate counter, and a common operating-slide, each of said mechanism being thrown into operative relation with said common operating-slide by its appropriate cam.

3. A fare-register comprising a series of independent counters for counting separate classes of fares, setting-cams mounted on a common shaft, one for each counter, connected link-and-lever mechanism between each cam and its appropriate counter, and a common operating-slide, each of said mechanisms being thrown into operative relation with said common operating-slide by its appropriate cam.

4. A fare-register comprising a series of independent counters for counting separate classes of fares, setting-cams mounted on a common setting-shaft, one for each counter, connected link-and-lever mechanism between each cam and its appropriate counter, and a common operating-slide, each of said mechanisms being thrown into operative relation with said common operating-slide by its appropriate cam.

The record shows that Ohmer filed his application February 9, 1903, and he is therefore entitled to that date for conception and reduction to practice.

In the preliminary statement filed by Neth and Tamplin the earliest date of conception of the invention by them is stated to be the "early part of November, 1903." As Neth and Tamplin's earliest date of conception is subsequent to the date of reduction to practice to which Ohmer is entitled, Neth and Tamplin cannot prevail in this proceeding. The record shows that a motion was brought by Neth and Tamplin to amend their preliminary statement after they had been made aware of the date of filing of Ohmer's application. On consideration of the showing made in their behalf the Examiner of Interferences denied this motion. On appeal his decision was affirmed on April 20, 1905, for reasons stated in that decision.

The decision of the Examiners-in-Chief awarding priority of invention to Ohmer is affirmed.

PARKES *v.* LEWIS.

Decided October 27, 1905

1. INTERFERENCE—APPEAL ON PRIORITY—MOTION TO TRANSMIT MOTION TO DISSOLVE NOT GRANTED.

Where the grounds for dissolution specified in Rule 122 were raised at the proper time and decided by the Primary Examiner and by the Examiners-in-Chief on appeal and the case is appealed to the Commissioner from a decision of the Examiners-in-Chief on the question of priority, a motion to transmit the interference to the Primary Examiner to consider the question of patentability will not be granted unless a clear and unmistakable error appears in the prior decisions.

2. SAME—AMENDMENT OF PRELIMINARY STATEMENT.

A motion to amend a preliminary statement to correct the inadvertent use of the word "model" instead of the words "full-sized machine" will not be granted where it is found that the device referred to as the "full-sized machine" does not disclose the issue.

3. SAME—REBUTTAL TESTIMONY RELATING TO PATENTABILITY STRICKEN OUT.

Rebuttal testimony which related solely to the patentability of the issue *Held* to have been properly stricken out.

APPEAL from Examiners-in-Chief.

SEWING-MACHINE.

Mr. William R. Baird for Parkes.

Messrs. Fowler & Bryson for Lewis.

ALLEN, *Commissioner:*

This is an appeal by Parkes from a decision of the Examiners-in-Chief affirming the decision of the Examiner of Interferences awarding priority of invention to Lewis as to the following issue:

1. In a sewing-machine, a rotary-hook mechanism arranged to remain in the same center of rotation, a laterally-reciprocating needle, and means for varying the depth of the thrust of said needle.

2. In a sewing-machine, a needle, means for vibrating said needle laterally, a rotary hook arranged to remain in the same center of rotation, and means for rotating said hook twice to each thrust of said needle.

At the hearing motions were made in behalf of Parkes to remand this interference to the Primary Examiner for the purpose of considering the question of patentability of the issues, also for leave to amend his preliminary statement. Appeal was also taken from that part of the decision of the Examiner of Interferences striking out certain testimony taken in rebuttal in behalf of Parkes, which testimony was held by the Examiner of Interferences to relate solely to the question of patentability and not, therefore, proper rebuttal testimony.

The questions of patentability of the issues and interference in fact, the right of the party Lewis to make the

claims, and irregularity in the declaration of interference were considered by the Primary Examiner on motion, and the motion to dissolve the interference was denied. The Examiner's decision was affirmed on appeal. These questions must be regarded as finally settled. The questions were raised at the proper time during the proceedings of this interference, considered, and determined. After appeal has been taken from the decision of the Examiners-in-Chief a motion to transmit an interference to the Primary Examiner will not be granted unless there should appear that a clear and unmistakable error has been committed in the prior decisions. No such error appears in this case, notwithstanding the testimony which has been submitted by Parkes on this question.

The question as to the amendment of Parkes's preliminary statement was also raised on motion and finally settled, for reasons which appear of record. As clearly appears from the record, the amendment to the preliminary statement if it had been permitted would not change the effect of the decisions which have been rendered on final hearing. It appears that Parkes originally stated in his preliminary statement that he made a model of the invention in 1897, and he sought to amend this statement by alleging that a full-sized machine was built by him at this time. He urged that he inadvertently called this machine a model; that the machines were not technically models, but were full-sized devices. The machine which has been introduced in evidence as "Parkes' Exhibit First Ornamental Stitch Machines" is admitted by Parkes not to disclose the issue. This machine was not produced at the hearing. The other machine marked "Parkes' Exhibit Second Ornamental Stitch Machine," which is testified to as being completed April, 1897, also does not disclose the issue, and therefore it is immaterial whether this machine is considered a full-sized working device or whether it is a model, as first stated by Parkes in his preliminary statement. In either event there is no disclosure of the invention contained therein. In this machine there is no "rotary-hook mechanism arranged to remain in the same center of rotation," which element is essential to each one of the appealed counts. In regard to the testimony which was taken in rebuttal in behalf of Parkes the Examiner was right in striking the same from the record; but, as has already been stated, this testimony does not warrant the remanding of the interference to the Primary Examiner for the purpose of determining again the question of patentability of invention.

The question of priority of invention, which is, in fact, the only proper question raised by this appeal, has been decided by the tribunals below in favor of Lewis, and that they are right in this finding is very clear from the record. Lewis filed his original application, of which the application involved in this interference is a division, on January 27, 1900. He is at least entitled to this date for conception and reduction to practice whatever may be the legal effect given to his 1899 machine. Lewis alleges that the testimony presented by him warrants the holding that this machine was an actual reduction to practice of the invention. For the purpose of this interference it is not necessary to decide whether Lewis is right in his contention or not, for it is immaterial whether Lewis be awarded actual reduction to practice in 1899 or whether he be regarded as reducing the invention to practice in January, 1900, when he filed his application for a patent. He is in either event the first to reduce to practice by at least a year, as Parks cannot be awarded a reduction to practice of the invention of the issue prior to December, 1900, as clearly appears from the testimony which has been so carefully analyzed by the Examiner of Interferences and set forth in his decision. It is also immaterial to this case whether Parkes is held to have been the first to conceive the invention or not, for it is very clear that he was lacking in diligence. As stated by the Examiners-in-Chief:

> The evidence indicates that he (Parkes) was provided with ample means, that according to his own admission the invention could easily have been embodied in a machine, and that he was making no effort to reduce the invention to practice at that the date of Lewis's parent application and made none for several months thereafter.
>
> It thus appears that whether or not Parkes was the first conceiver, he cannot prevail in this controversy.

The decision of the Examiners-in-Chief awarding priority of invention to Lewis is affirmed.

EX PARTE AMERICAN GLUE COMPANY.

Decided December 13, 1905.

TRADE-MARKS—COAT OF ARMS—"TEN YEARS'" CLAUSE.

The coat of arms of the United States is not registrable as a trade-mark even under the "ten years'" clause of the law.

ON APPEAL.

TRADE-MARK FOR FLINT, ETC.

Mr. Vere Goldwaithe for the applicant.

ALLEN, *Commissioner:*

This is an appeal from the action of the Examiner of Trade-Marks refusing to register a mark described as follows:

> The trade-mark consists of the words "New England" together with a representation of a spread-eagle holding in its talons arrows and an olive branch and having a shield upon its breast.

It is clear upon inspection, and the appellant admits in his brief, that the mark includes the coat of arms of the United States. Section 5 of the act of February 20 expressly prohibits the registration of marks including the coat of arms of a nation, and it is because of the inclusion of the coat of arms that the Examiner has refused registration in this case.

It is clear that the Examiner is right in his ruling. The contention is made on behalf of the appellant that the prohibition against the registration of a mark including the coat of arms in a registered trade-mark has no application to marks alleged to have been in actual and exclusive use for ten years, and attention is called to the fact that such allegation of use has been made in this case. The question here involved was fully discussed and was decided in the case of *Cahn, Belt & Company*, (118 O. G., 1936.) For the reasons there stated it is held that this Office is justified in refusing registration of a mark presented under the "ten years'" clause of the law where it includes the coat of arms of a State or nation.

It is noted that the appellant has filed a substitute description of his mark curing certain objections made by the Examiner and that therefore it is unnecessary to refer to those objections.

The decision of the Examiner refusing registration is affirmed.

MOORE *v.* CURTIS.

Decided December 13, 1905.

1. INTERFERENCE — MOTION TO AMEND — CONSIDERATION OF RIGHT TO MAKE PROPOSED CLAIMS.

Upon petition that the Examiner be directed to hear a party upon his opponent's motion to amend on the question of his opponent's right to make proposed claims, *Held* that petitioner may present his arguments upon motion for dissolution in case the proposed claims are admitted.

2. HEARINGS—DURATION—DISCRETION OF EXAMINER.

Where upon petition that the Examiner be directed to hear further a party on motion in interference it appears that no hardship or irreparable injury will be suffered through the Examiner's refusal to hear, *Held* that the Examiner would not be controlled in the exercise of his discretion as to the duration of the hearing.

ON PETITION.

TURBINES.

Mr. Thomas D. Stetson and *Mr. C. J. Hedrick* for Moore.

Messrs. Dyer & Dyer for Curtis.

ALLEN, *Commissioner:*

This is a petition by Moore requesting that the Primary Examiner be directed to hear the petitioner on the right of Curtis to make certain claims which have been proposed by Curtis for addition to the issue upon motion under Rule 109.

It appears that the motion was transmitted and that the Primary Examiner gave a hearing thereon, at which the petitioner appeared by counsel and was heard. It also appears that the Examiner after the petitioner had been heard for a certain time refused to hear the petition further, and it is in view of this refusal that this petition has been brought, the petitioner alleging that he was not notified in advance that he would be heard for a limited time only and that through the unexpected limitation of the hearing by the Examiner the petitioner was prevented from presenting his case upon the right of Curtis to claim the proposed counts. The practice permits Moore to present his arguments in opposition to Curtis's right to make the proposed claims upon motion for dissolution of the interference in the event that the claims should be found acceptable by the Primary Examiner and should, in fact, be included in the interference. (*Jenne* v. *Brown* v. *Booth*, 59 O. G., 157; *Pfingst* v. *Anderson*, 114 O. G., 264.) It does not appear that the petitioner can suffer any hardship or irreparable injury through the refusal of the Examiner to hear him further at this time. Under such circumstances the Examiner should not be controlled in the exercise of his discretion as to the duration of the hearing.

Petition denied.

GALLY *v.* BURTON.

Decided December 18, 1905.

1. INTERFERENCE—DISSOLUTION—FAILURE TO INCLUDE CLAIMS MADE BY BOTH PARTIES.

Failure to include in the issue certain claims made by both parties does not constitute an irregularity where such claims are not patentably different from those which were included.

2. SAME—SAME—CLERICAL ERRORS DO NOT WARRANT DISSOLUTION.

The omission or improper use of hyphens in the counts of an issue and the use of the word "power" instead of the word *primary* are mere clerical errors, which may be corrected by a letter of the Primary Examiner calling attention to them, and they furnish no reason for dissolving the interference on the ground of irregularity in the declaration.

APPEAL on motion.

SELF-PLAYING MUSICAL APPARATUS.

Mr. Robert A. Gally pro se.

Messrs. Burton & Burton for Burton.

ALLEN, *Commissioner:*

This is an appeal by Gally from a decision of the Primary Examiner refusing to dissolve the interference on the ground of irregularity in the declaration thereof.

Gally is a patentee, and six of his claims were suggested by the Examiner to the appellee, Burton. The appellee adopted all of the claims; but the Examiner considered that it was necessary only to include three of such claims in the issue, and so declared the interference. The appellant contends that the failure to make each of such claims an issue in the interference constituted such an irregularity in the declaration thereof as will preclude a proper determination of the question of priority, because the three claims which have not been included in the interference differ in substance from those which were included, and it is therefore possible "that the party who prevailed on priority might do so on proofs of an invention answering to the issue, but not to the other claims, yet would be awarded by the Office those claims as well, although such particular forms of invention might actually have been the prior invention of the losing party to the broad issue." But this result would not follow unless the claims were patentably different. It seems that appellant agrees with this proposition, but asserts that the claims are patentably different, pointing out certain limitations which are found in the unincluded claims which are not found in the counts of the issue. These differences do exist, as stated by appellant, and the Primary Examiner recognizes this fact, but has held that the limitations are not such as render the claims including them patentable over the issue. The Examiner therefore declared the interference in accordance with the practice laid down in *Votey* v. *Wuest, Jr.*, v. *Doman*, (111 O. G., 1627.) On this appeal appellant does not give any reasons why he regards the claims in question as being patentable over the issue, except that they are somewhat different in scope and that the Examiner has practically admitted that they are patentably different, because otherwise he would not have suggested *all* of them to appellee. But when it is stated that the claims are not patentably different from the counts of the issue it is meant that they cannot be allowed to two different parties. They might all be allowed to one of the parties; but the three claims of the issue could not be allowed to one party and the other three claims to the other party, no matter what the proofs might be.

Another reason given in support of the appeal is that certain hyphens have not been used where they should have been used. This is a matter which does not change the meaning of the claims in any way and is immaterial. It is also asserted that a hyphen has been improperly used, and the word "power" is used where the word *primary* should have been used; but these are mere clerical errors, which were sufficiently corrected by the Examiner in a letter written to the Examiner of Interferences calling attention to them, which letter is a part of the record of this interference.

It appears that there has been no such irregularity in the declaration of this interference as will preclude a proper determination of the question of priority, and the decision of the Primary Examiner is therefore affirmed.

EX PARTE A. G. SPALDING & BROS.

Decided December 21 1905.

1. TRADE-MARKS—DESCRIPTION OF PARTICULAR GOODS—STATUTORY REQUIREMENT.

Where a trade-mark application said that the mark had been

used upon "implements, apparatus, and goods used in athletic games and sports," registration was properly refused on the ground that the statutory requirement for a description of the particular goods had not been complied with.

2. SAME—SAME—INDEFINITENESS—PRIMA FACIE RIGHT.

A description which is so indefinite as to convey no intelligible idea of the particular goods upon which the mark has been used is not a compliance with the statute and does not make out a *prima facie* right to registration.

3. SAME—USE UPON PARTICULAR GOODS NECESSARY—FACTS, NOT CONCLUSIONS, MUST BE STATED.

An applicant's right to registration of a trade-mark is dependent upon his use of it upon some specific goods, and under the terms of the statute the facts upon which the right is based must be stated, leaving the scope of the right acquired for subsequent judicial determination.

4. SAME—SAME—GOODS NOT OF SUBSTANTIALLY THE SAME DESCRIPTIVE PROPERTIES.

Where the description of the goods upon which the mark has been used is in such broad and general terms as to include goods which are not of substantially the same descriptive properties, registration must be refused on the ground that the application is not limited to a single trade-mark right.

5. SAME—DIVISION—SINGLE TRADE-MARK RIGHT

A single trade-mark registration should include only a single trade-mark right, and a single right extends no further than to merchandise having substantially the same descriptive properties.

6. SAME—SAME—ACTS OF 1881 AND 1905 COMPARED.

The act of 1905 contains the same provisions and has the same meaning as the act of 1881 in so far as the limitation to goods of substantially the same descriptive properties is concerned.

ON APPEAL.

TRADE-MARK FOR ATHLETIC SUPPLIES.

Messrs. Redding, Kiddle & Greeley and *Mr. A. P. Greeley* for the applicants.

ALLEN, *Commissioner:*

This is an appeal from the action of the Examiner of Trade-Marks rejecting the above-entitled application for trade-mark registration on the ground that the application does not include a particular description of the goods to which the mark has been applied, as required by the statute, and upon the further ground that the application covers more than one trade-mark right.

It is said in the application:

> The class of merchandise to which the trade-mark is appropriated is athletic supplies, and the particular description of the goods comprised in said class upon which said trade-mark is used is implements, apparatus, and goods used in athletic games and sports.

This is the only description of goods contained in the application, and it is obviously so indefinite as to convey no intelligible idea of the particular goods upon which the mark has been used.

The right to registration is founded upon the common-law right which can be acquired only by use of the mark upon some particular articles of trade. The statute contemplates and requires that the applicant state not merely the class of goods, but the particular goods within the class upon which the mark has been used. Section 1 of the act of February 20, 1905, says he shall state—

> the class of merchandise and the particular description of goods comprised in such class to which the trade-mark is appropriated.

This requirement for a statement of the particular goods upon which the mark has been used was evidently placed in the law to prevent fraud and imposition upon the public. The applicant was not to be permitted to determine for himself the scope of his trade-mark right and secure the sanction of this Office for his claim without disclosing the facts upon which his claim is based. However broad his right, it is based upon the use of the mark upon some specific goods. It seems perfectly clear that the appellants may have used their mark upon *some* "implements, apparatus, and goods used in athletic games and sports" without acquiring a common-law right to exclude others from using the mark upon other "implements, apparatus, and goods used in athletic games and sports." In other words, it does not follow from use upon some of the goods that the appellants' right extends to all goods within the alleged class, and therefore their statement is too indefinite to establish even a *prima facie* right.

The applicants should have specified the particular goods upon which they have used the mark, leaving it to the courts to determine whether or not their right includes the whole field of athletic goods. In other words, they should furnish the specific material upon which the conclusion is based, and not merely the conclusion. If they are wrong in their conclusion, they mislead the public and furnish nothing by which their error may be detected. Registration in such a case is a fraud upon the public.

The Examiner was clearly right in refusing registration, because the applicants have not complied with the statutory requirement for a statement of the particular goods upon which the mark has been used.

While the appellants' statement fails to mention the specific goods, the broad and general terms used by them include a great variety of goods of entirely different characters. As above stated, it is impossible to determine from the appellants' statement whether they have acquired trade-mark rights upon all goods coming within the terms of their indefinite description; but it is very clear that if they have such rights they constitute more than one trade-mark right. All goods coming within the indefinite terms of description are not of substantially the same descriptive properties. It is clear that different parties might use the same mark upon different goods coming within the description without bringing about a conflict of rights. This is because there is no such similarity between any and all implements or apparatus used in any and all athletic sports or games as to make one believe that they have the same origin or ownership merely because the same mark appears upon them. This is because athletic sports and games are of great variety, and the implements and apparatus used in them are subject to the same variety and include articles having no resemblance to each other, either in appearance or use, and which are of such diverse character that they are usually, if not always, made by different manufacturers.

In the case of *Faxon* (103 O. G., 891) it was pointed out that under the act of 1881 a single trade-mark registration should include only a single trade-mark right and that a single right extended no further than to merchandise having substantially the same descriptive properties. The reasons for the ruling were fully stated there, and it is unnecessary to repeat them here.

When the act of February 20, 1905, was passed, revising the entire trade-mark law, no change was made in those provisions upon which the decision in the *Faxon Case* was based. The same words were used in this new law, and therefore it has the same meaning. (*Ex parte The Chas. H. Phillips Chemical Co.*, 119 O. G., 652.) It is to be presumed that Congress would have changed the wording of the new law if it had intended that it should have a different meaning from that which had been found in the old law.

The appellants are not entitled to registration, since they have not made out a *prima facie* case of ownership at common law by specifying the particular goods upon which they have actually used the mark, as required in the statute, and since the claim made by them includes many separate trade-mark rights which cannot be included in a single registration.

The decision of the Examiner of Trade-Marks is affirmed.

EX PARTE GRISERIN-WERKE PAUL CAMPHAUSEN
G. M. B. H.

Decided December 28, 1905.

1. TRADE-MARKS—"PENDING" CASES—REJECTION BY EXAMINER.

A trade-mark application is not to be regarded as adjudicated and as not "pending" within the meaning of sections 14 and 24 of the act of 1905 merely because it had been rejected by the Examiner.

2. SAME—SAME—SAME—FINAL ADJUDICATION.

The mere rejection by the Examiner of a trade-mark application under the act of 1881 did not finally dispose of it, since it was subject to amendment and reconsideration if request therefor were made within a reasonable time.

3. SAME—SAME—APPEAL—UNREASONABLE DELAY.

While a trade-mark application is not taken out of the class of pending cases merely because it has been rejected, it is taken out of that class where the right of appeal was exhausted and where there has been unreasonable delay in prosecuting the application.

4. SAME—SAME—ABANDONMENT.

Where after rejection the trade-mark applicant abandoned all intention of further prosecuting the case, it was not a live or pending case, but was abandoned.

5. SAME—SAME—DELAY IN PROSECUTION—EVIDENCE OF ABANDONMENT

Failure to take any action in prosecution of an application for a long period of time is evidence of an intention to abandon the application and in the absence of proof to the contrary is to be taken as establishing the fact.

6. SAME—SAME—LACHES—APPLICATION NOT NOTICE.

An application for the registration of a trade-mark is not notice to the public through this Office of the applicant's claim of ownership unless that application is prosecuted with reasonable diligence. The application is abandoned by laches.

7. SAME—SAME—DELAY OF ONE YEAR UNREASONABLE.

No hard and fast rule can be laid down as to what delay will be regarded as an abandonment of a trade-mark application; but ordinarily a delay for more than one year will be deemed unreasonable unless excuse is made therefor.

8. SAME—ANTICIPATION—"GRISERIN" AND "ELECTRENE."

The trade-mark "Griserin" does not so nearly resemble the mark "Electrene" as to deceive purchasers.

ON APPEAL.

TRADE-MARK FOR MEDICINAL PREPARATIONS.

Messrs. Knight Bros. for the applicant.

ALLEN, *Commissioner:*

This is an appeal from the action of the Examiner of Trade-Marks refusing registration on the ground that no valid application has been filed under the Trade-Mark Act of February 20, 1905, which is now in force.

It appears that application for registration was filed under the act of 1881 on December 23, 1904, and that the Examiner of Trade-Marks wrote a letter on January 5, 1905, refusing registration in view of a prior registration, No. 27,094, September 24, 1895, granted to one Reynolds. He also made certain formal objections. On April 17, 1905, the applicant filed an amendment curing the formal objections and seeking to bring the application under the act of February 20, 1905. The Examiner refused to admit this amendment, saying:

> Applicant is not entitled to amend this application to bring the same under the provision of the act of February 20, 1905, for the reason that the application is not a pending application under the act of 1881, having been refused registration in Office letter of January 5, 1905.

Upon request for reconsideration the Examiner repeated his ruling, but also called attention to formal defects in the amendment. Another amendment was then filed, being in form such as required by sections 14 and 24 of the act of 1905. The Examiner refused to admit the amendment or to consider the application as one pending upon which registration might be granted. This appeal was thereupon taken, and it presents for determination the question whether this application was pending at the time of the passage of the act of February 20, 1905.

The Examiner's action in this case was based upon my ruling in *ex parte Mark Cross Company*, (116 O. G., 1733,) where it was said:

> In the present case it surely is not unreasonable to suppose that Congress intended the word "pending" to have the ordinary meaning and to apply to cases which had not been adjudicated. It was to be presumed that there would be applications in this Office filed under the act of 1881 and not disposed of at the time the new law was to take effect. It was obviously proper and reasonable to preserve the rights of these applicants and provide for an adjudication of their cases. The word *pending* plainly refers to these cases, and it cannot be applied to adjudicated cases without giving it a forced and unnatural construction.

The Examiner points out that the present case had been acted upon and "adjudicated" by him and that therefore under the above ruling it was not pending when the law of 1905 took effect. He was justified in taking such position in view of the decision cited and would not have been justified in allowing the present case unless and until some higher tribunal modified the ruling or construed the term "adjudicated" to mean something more than a mere letter of rejection by the Examiner.

It does not follow, however, that it is finally determined that no applications which stand rejected when the act of February 20, 1905, took effect are to be regarded as pending at that date. My attention has been called to several cases in which there would be manifest hardship in holding that the applications were not pending, although they had been rejected. In some instances the rejection was made so late that it was impossible for the applicant to ask for reconsideration or to appeal before the new law went into effect. In others the applicants show that they were diligently engaged in investigating the alleged prior ownership of the mark by another, cited as the reason for rejecting the application, and at the time the act of 1905 took effect had not completed that investigation. They were unable to present to this Office the result of that investigation with a request for reconsideration until after the new law took effect.

In the matter of collecting for the Government fees for services rendered by this Office it is believed that the fee should not be remitted by the executive branch of the Government in any case where there is reasonable doubt as to the intention of Congress. The executive officer of the Government should collect the fees in case of doubt, leaving the parties to their remedy by action in the courts, whose functions are to determine finally just such questions.

In the present case, however, I have reached the conclusion that there is no reasonable doubt of the fact that the application was pending within the meaning of the act of

February 20, 1905, at the time of its passage. The mere rejection of the case by the Examiner did not finally dispose of it. It was subject to amendment and reconsideration if request therefor were made within a reasonable time. It was to be expected that the applicant would ask for reconsideration or appeal within a reasonable time if it did not wish to acquiesce in the adverse ruling. The applicant did, in fact, ask for reconsideration without unreasonable delay, and I am convinced that it was not the intent of Congress to deprive it of that right merely because in the meantime the new law was passed and went into effect.

While I am satisfied, after thorough consideration, that Congress did not intend to require a new application and new fee in order to entitle a trade-mark claimant to secure an adjudication which he was entitled to secure and was diligently seeking to secure on his application under the old law, I am equally well satisfied that the word "pending" in the act of 1905 does not include and was not intended to include all applications rejected under the act of 1881 merely because the applicant had not taken advantage of the right of appeal given him by the rules.

It is perfectly clear that many applications had been rejected by the Examiner and abandoned by the applicants long before the act of 1905 was passed. Where after rejection the applicant abandoned all intention of further prosecuting the case, it is clear that the case was not a live or "pending" case. Failure to take any action for a long period of time is evidence of such abandonment and in the absence of proof to the contrary is to be taken as establishing the fact.

A suit in the courts must be prosecuted with reasonable diligence in order to operate as notice or to have the effect of *lis pendens*. (*Am. and Eng. Encycl. of Law*, vol. 21, p. 622; *Redfield* v. *Ystalyfera Iron Co.*, 110 U. S., 174.) So here an application for registration of a trade-mark is not notice to the public through this Office of the applicant's claim of ownership unless that application is prosecuted with reasonable diligence. Long and unexcused delay shows an abandonment of the proceeding, and this Office is justified in regarding it as no longer notice of the party's claim to the alleged trade-mark. In regard to diligence of prosecution it is said in *American and English Encyclopædia of Law*, (vol. 21, p. 623:)

> No hard and fast rule, however, can be laid down for the government of all cases, but the question of reasonable diligence in prosecuting must of necessity depend upon the particular facts and circumstances of each case.

While no hard and fast rule can be laid down as to what delay will be regarded as an abandonment of a trade-mark application, it may be said that ordinarily a delay for more than a year will be deemed unreasonable unless excuse is made therefor. Congress has deemed one year a reasonable time for acting upon patent applications, and no reason is apparent why a longer period should be required in trade-mark cases. The analogy is as close as that which was the basis of the ruling by the Supreme Court that reissue applications should be made within two years after the date of the patent. (*Topliff* v. *Topliff*, 145 U. S., 156.)

It must be held that a trade-mark application was not "pending" at the time of the passage of the act merely because no final decision in the case had been rendered by the Commissioner in person on appeal, as in the case of *Mark Cross Co.*, (116 O. G., 2534.) Any unreasonable delay, particularly after adverse judgment by the Examiner, takes the case out of the class of live or pending applications, and, as above stated, a delay of more than one year will be regarded *prima facie* as unreasonable.

Since there was no unreasonable delay in the present case, it must be regarded as pending at the time of the passage of the act of February 20, 1905.

This appellant's trade-mark consists of the word "Griserin," and the mark registered by Reynolds and cited originally as the ground of rejection consists of the word "Electrene." There is no such resemblance between the marks as would deceive purchasers, and it is probable that the Examiner would have withdrawn his rejection upon reconsideration if he had felt at liberty to regard the application as one properly before the Office for consideration under the act of 1905.

The decision of the Examiner of Trade-Marks is reversed.

Date of Patent.

RULE 207. The weekly issue closes on Thursday, and the patents of that issue bear date as of the third Tuesday thereafter. If the final fee in any application is not paid on or before Thursday, the patent will not go to issue until the following week.

Trade-Marks.

The publication of trade-marks under the act of February 20, 1905, in the OFFICIAL GAZETTE, commenced MAY 2, 1905, and will appear in each weekly number of the GAZETTE thereafter.

Extra copies of the trade-mark portion of the GAZETTE, which will be sold separately, may be obtained single or in quantities for five cents each. Coupons will be taken in payment therefor.

Payment of Patent Fees.

RULE 207. All payments of money required for Office fees must be made in specie, Treasury notes, national-bank notes, certificates of deposit, post-office money-orders, or certified checks. Money-orders and checks should be made payable to the "Commissioner of Patents." Payment may also be made to the Treasurer, or to any of the assistant treasurers of the United States, or to any of the depositaries of national banks, or receivers of public money, designated by the Secretary of the Treasury for that purpose, who shall give the depositor a receipt or certificate of deposit therefor. *This receipt or certificate of deposit shall, in case of payment of final fees, be deposited in the mail for transmission to the Patent Office, within six months from the allowance of the application.* Money sent by mail to the Patent Office will be at the risk of the sender. Letters containing money should be registered. In no case should money be sent with models.

RULE 208. The weekly issue closes on Thursday, and the patents of that issue bear date as of the third Tuesday thereafter. If the final fee in any application is not paid on or before Thursday, the patent will not go to issue until the following week.

Full Names of Applicants.

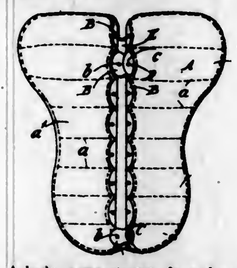
* * * All applications which disclose the full name of the applicant in the preamble of the specification will be received and considered as a sufficient compliance with Rule 40 of the Rules of Practice. (Order 881.)

When the full first name of the applicant does not appear either in his signature or in the preamble to the specification, the Examiner will, in his first official letter, require an amendment supplying the omission, and he will not pass the application to issue until the omission has been supplied, unless an affidavit shall have been filed setting forth that the full first name of the applicant is the one originally given by him. (Order 688.)

PATENTS

GRANTED JANUARY 9, 1906.

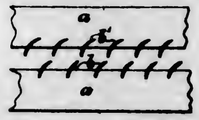
809,276. **HARNESS LINING AND PAD AND THE LIKE.** EMMA M. AULTON, Bushbury, near Wolverhampton, England. Filed Dec. 7, 1903. Serial No. 184,166.



Claim.—1. A body, compartments formed on the body, said compartments having one end open, flaps for closing the open ends of the compartments said flaps having apertures, bladders insertible in the compartments and flexible tubes carried by the bladders, said tubes passing through the apertures of the flaps to confine the bladders within the compartments and to hold the flaps in closed position.

2. A body, compartments formed on the body, said compartments having one end open, flaps for closing the open ends of the compartments, said flaps having apertures, bladders insertible in the compartments, flexible tubes carried by the bladders, said tubes passing through the apertures of the flaps to thereby confine the bladders within the compartments and to hold the flaps in their closed positions, and means for holding the body in applied position.

809,277. **TURBINE.** JOHN H. BARKER, Newcastle-upon-Tyne, England, assignor to Charles Algernon Parsons, Newcastle-upon-Tyne, England. Filed Sept. 26, 1905. Serial No. 280,147.



Claim.—1. A bladed turbine-drum comprising in combination a plurality of rings, blades carried by said rings so that the blades project from the lateral face of said rings, the rings being associated so that the blades projecting from adjacent faces of the rings come into alinement, substantially as described.

2. A bladed turbine-drum having a plurality of rings, blades carried by the rings and spaced at double the circumferential pitch required, the blades being arranged to project laterally from the rings for one-half the width of the blades and the rings being associated so that the blades projecting from contiguous faces of the rings fall into alinement, substantially as described.

3. The combination of a ring *a* having the alternate blades of a row formed thereon so as to project laterally for one-half the width of the blade, an adjacent ring similarly carrying the remainder of the blades which form the complete row, bolts *c* binding a plurality of such associated blade-carrying rings, substantially as described.

809,278. **PROCESS OF PRODUCING SOLUTIONS CONTAINING PURE SILVER SALT.** WALTHER DÉSAEGHER, Winterthur, Switzerland. Filed July 6, 1905. Serial No. 268,592.

Claim.—The herein-described process of producing a solution containing pure silver salt, consisting in dissolving in about thirty liters of water 0.8 kilogram of silver salts, which are then precipitated as chlorid with diluted hydrochloric acid of twelve per cent. and the deposit washed out, whereupon in a reducing solution of about thirty liters of water and 3.3 kilograms of hyposulfite of soda the precipitated chlorid of silver is dissolved while being constantly stirred and with this solution are mixed, while the same is being stirred, first 1.8 kilograms of caustic ammonia of eight per cent. and then eight kilograms of finely-triturated Spanish whiting, whereby double salts are formed of which the following can be traced:

$$Ag_2S_2O_3 \text{ and } Ag_2S_2O_3Na_2S_2O_3H_2O,$$

substantially as and for the purpose set forth.

809,279. **PROCESS FOR THE PRODUCTION OF STOVE-POLISH.** ANTON N. BRAUN, Arad, Austria-Hungary. Filed Aug. 12, 1905. Serial No. 273,977.

Claim.—1. Process for the production of a stove-polish consisting in dissolving gum-arabic in distilled water, boiling the mixture with spirit of turpentine while the gum-arabic is dissolving, and adding a pulverized alloy of aluminium and tin substantially as described.

2. Process for the production of a stove-polish consisting in dissolving gum-arabic in distilled water, boiling the mixture with spirit of turpentine while the gum-arabic is dissolving, adding to part of this product a pulverized alloy of aluminium and tin, diluting the latter product with the remainder of the gum-arabic and turpentine solution and stirring the whole substantially as described.

3. Process for the production of a stove-polish consisting in dissolving twelve parts gum-arabic in seventy-four parts distilled water, boiling the mixture with four parts spirit of turpentine while the gum-arabic is dissolving, mixing thirty parts of the product with ten parts pulverized alloy of aluminium and tin in equal proportions, diluting the latter mixture with the remainder of the gum-arabic and turpentine solution and stirring the whole substantially as described.

809,280. **BEARING FOR VERTICAL SHAFTS.** EDGAR W. BROCKALL, Rochester, N. Y. Filed June 24, 1905. Serial No. 266,535.

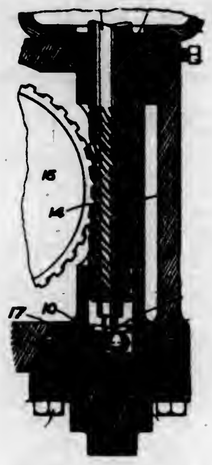
Claim.—1. The combination with a suitable support, of a shaft-supporting sleeve mounted in said support and open at one side for the driving means, a step-bearing in the lower end of the sleeve, a shaft mounted in the sleeve and stepped at its lower end in said step-bearing, and means for yieldingly connecting the lower end of the sleeve to the support.

2. The combination with a suitable support, of a sleeve provided with an apertured flange at its lower end and passed upwardly through an opening in said support, screws passed loosely through the flange-aperture upwardly into the lower side of the support, and springs between the flange and support.

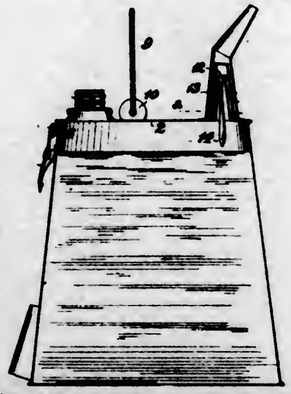
3. The combination with a suitable support, of a shaft-supporting sleeve open at one side for the driving connections, a step-bearing in the lower end of the sleeve for said shaft, an apertured flange being provided on the sleeve below the support, screws passed loosely through said flange-apertures into the lower side of said support, and springs on the screws between the flange and support.

4. The combination with a support and a shaft-supporting sleeve passed upwardly through an opening in the support and there provided with an annular pivot-ledge, screws passed up loosely through the flange-apertures into the lower side of the support, springs between the flange and support, of a cup in the lower portion of the sleeve, three balls in the cup, a plug closing the lower end of the sleeve and holding the cup in place, and a shaft within the sleeve and having a pointed lower end stepped between the balls.

809,280.



809,281. SAFETY DEVICE FOR OIL-CANS. BENEDETTO BUCCIERI, Sharpsburg, Pa., assignor of one-half to Vincenzo De Luca, Pittsburg, Pa. Filed June 23, 1905. Serial No. 266,640.



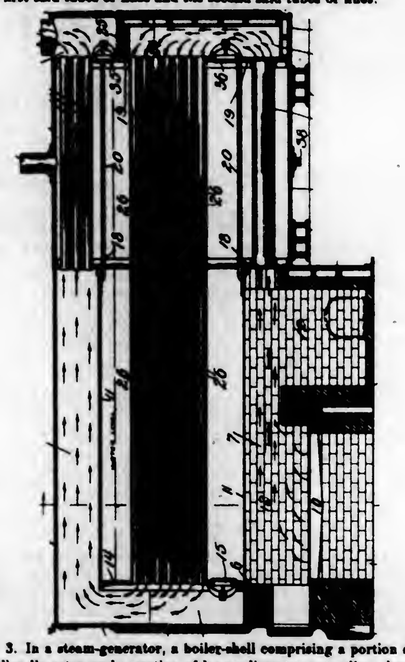
Claim.—1. The combination, with an oil-can, of a spout, an open-ended discharge-tube therein, a check or non-return valve controlling said discharge-tube, a closing-weight fixed to said valve, and a perforated casing interposed between the discharge-tube and the spout.

2. The combination, with an oil-can, of a spout, an automatically-acting valve controlling communication between the spout and the interior of the can, and a perforated casing interposed between the valve and the spout.

809,282. STEAM-GENERATOR. THOMAS R. BUTHAN, Lake Bluff, Ill. Filed Dec. 21, 1904. Serial No. 237,142.

Claim.—1. In a steam-generator, a horizontal boiler-shell comprising a portion of smaller diameter, and a portion of larger diameter extending above the top of the portion of smaller diameter to provide a water-space in its lower portion aligning with that of the portion of smaller diameter, and a steam-space in its upper segment, and passages for conducting gases through the water-space and subsequently through the steam-space in the larger portion of the shell.

2. In a steam-generator, a boiler-shell comprising a portion of smaller diameter and a portion of larger diameter, extending above the top of the portion of smaller diameter to provide a water-space in its lower portion aligning with that of the portion of smaller diameter, and a steam-space in its upper segment, tubes or flues taking through the joint length of said portions from end to end of the shell, superheating tubes or flues taking through the steam-space in the larger portion of the shell, and means for directing gases successively through the first said tubes or flues and the second said tubes or flues.



3. In a steam-generator, a boiler-shell comprising a portion of smaller diameter, and a portion of larger diameter, extending above and below the portion of smaller diameter, gas-passages through the lower segment of the portion of larger diameter, a main battery of tubes extending through the shell from end to end, passages through the upper segment of the portion of the shell of larger diameter, and means for directing the heating medium successively through the passages and tubes in the order named.

4. In a steam-generator a source of heat-supply, a boiler-shell having a portion of smaller diameter and a portion of larger diameter, the portion of smaller diameter being directly exposed to the heat, water-heating passages through the lower segment of the enlarged portion of the shell, water-heating tubes extending throughout the entire length of the shell, and superheating-tubes extending through the upper segment of the enlarged portion of the shell, and means for directing the heat successively through said passages and tubes in the order named.

5. In a steam-generator, a boiler-shell comprising a portion of smaller diameter and a portion of larger diameter, water-heating tubes or flues extending through the lower arc of the enlarged zone of the shell, superheating-tubes extending through the upper arc of the enlarged zone of the shell, a heat-generator arranged to primarily heat the portion of the shell of smaller diameter, and means for directing the heated gases through the water-heating tubes and superheating-tubes.

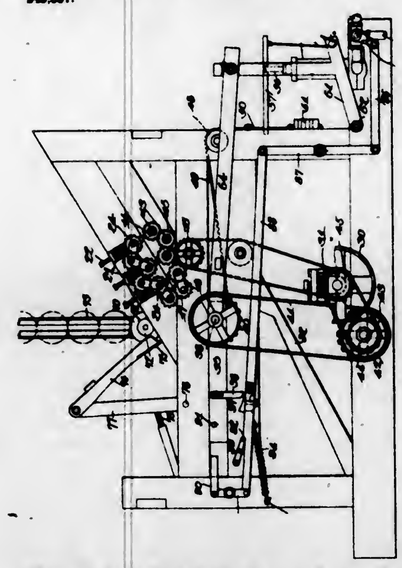
6. In a steam-boiler, a shell comprising a cylinder of smaller diameter and a cylinder of larger diameter arranged end to end in open communication, heads for the opposite ends of the cylinders, and braces for the head of the larger cylinder at one end secured to said head, and at their other ends secured to the smaller cylinder.

7. In a steam-generator, a shell comprising a portion of smaller diameter and a portion of larger diameter, passages through the lower segment of the portion of larger diameter, tubes through the upper segment of said portion, a source of supply of a heating medium, and means for directing the heating medium successively through the passages and tubes in the lower and upper segments of said larger portion of the shell.

8. In a steam-generator, a shell comprising a portion of smaller diameter and a portion of larger diameter, flues through the lower segment of the larger portion of the shell, tubes through the upper segment of the larger portion of the shell, a source of supply of a heating medium, and means for directing the heating medium sequentially through said flues and tubes.

9. In a steam-generator, a shell having a front portion of relatively small diameter and a rear portion of relatively large diameter, a passage in rear of said shell, and a partition-wall in said passage dividing it into two uptakes, an uptake at the front end, a passage over the smaller part of the shell communicating with the front uptake, a furnace arranged to directly heat the lower surface of the smaller portion of the shell, tubes or flues taking through the lower segment of the enlarged portion of the shell arranged to receive heat from the furnace and opening into the lower rear uptake, fire-tubes taking through the shell from end to end and opening into the lower rear uptake and the front uptake, tubes taking through the upper segment of the enlarged portion of the shell opening into the passage over the front of the shell, and into the upper rear uptake, and an outlet flue communicating with the upper rear uptake.

809,283. MACHINE FOR FORMING ROUND COTTON-BALES. CARTER M. CAGLE, Beckville, Tex. Filed Jan. 31, 1906. Serial No. 243,537.



Claim.—1. In a bale-forming machine, a belt, a transfer-roller serving as a bale-forming means, and means for imparting movement to the belt, the bale being formed serving as a friction member for transmitting movement from the belt to the roller.

2. In a baling-press, a compression means, and means under the control of the bale being formed for automatically moving the compression means to inoperative position when said bale has reached a predetermined size.

3. In a baling-press, a compression-roller, and means for automatically moving the same to inoperative position when the bale has reached a predetermined size.

4. In a baling-press, a compression-roller, means for automatically moving the roller to inoperative position, and means for adjusting the time of operation in accordance with the diameter of the bale to be formed.

5. In a baling-press, a compression-roller, a movable frame supporting the roller, means for moving the roller out of contact with the bale, and mechanism operable by the movement of the frame for controlling the operation of the roller-moving means.

6. The combination in a baling-press, of a compression-roller, a frame carrying the same, frame-engaging means for adjusting the roller to inoperative position, and an adjustable mechanism operable by the frame for controlling the operation of said frame-engaging means.

7. The combination in a baling-press, of a compression-roller, a frame carrying the same, a fluid-pressure-actuated mechanism for moving the roller to inoperative position, and means controlled by said frame for governing the supply of fluid under pressure to said mechanism.

8. The combination in a baling-press, of a compression-roller, a movable frame carrying said roller, a fluid-pressure-operated means for engaging said frame, and adjusting the rollers to inoperative position, a normally closed valve for governing the flow of fluid under pressure to said mechanism, and means operable by the frame for opening said valve.

9. The combination in a baling-press, of a compression-roller, a slidable frame for said roller, a fluid-pressure-operated mechanism for moving the roller to inoperative position, a valve for controlling the flow of fluid under pressure to such mechanism, and valve-operating rods disposed in the path of movement of said frame.

10. The combination in a baling-press, of a compression-roller, a slidable frame carrying said compression-roller, a fluid-pressure-operated mechanism for moving the roller to inoperative position, a valve controlling the flow of fluid to said mechanism, a valve-operating rod having a locking-shoulder, a fixed stop for engaging the shoulder, a valve-opening spring engaging the rod, and adjustable means operable on movement of the frame for moving said shoulder from engagement with the stop.

11. The combination in a baling-press, of a compression-roller, a movable frame carrying said roller, a fluid-pressure-operated mechanism for moving said roller to inoperative position, a valve for controlling the flow of fluid under pressure to said mechanism, a valve-operating rod having a locking-shoulder, a fixed stop with which said shoulder engages, a spring engaging the rod and serving when the latter is released to move the valve to open position; an adjustable cam carried by the rod, and a lug or finger carried by the frame and adapted to engage said cam.

12. The combination in a baling-press, of a compression-roller, a movable frame carrying said roller, a fluid-pressure-operated means engaging said frame, a normally closed valve controlling the flow of fluid to and from said means, and valve-operating means carried by the frame.

13. The combination with a compression-roller, of a movable frame carrying said roller, a fluid-pressure-operated means engaging said frame, a valve for controlling the flow of fluid under pressure to and from said means, a valve-operating device, and means carried by the frame for engaging said device and first opening and then closing said valve.

14. The combination in a baling-press, of a compression device, and means for automatically moving the same into and out of operative position.

15. The combination in a baling-press, of a compression means, means for automatically moving the same to inoperative position at the completion of each bale-forming operation, and mechanism for restoring the compression means to operative position after the discharge of a finished bale.

16. The combination in a baling-machine, of a compression-roller, a slidable frame carrying said roller, a weight connected to the frame and tending to hold the roller in engagement with the bale, a fluid-pressure cylinder, a piston in said cylinder, links forming a connection between the piston and the frame, and means connecting the piston to the link to adjust the roller to inoperative position.

17. The combination in a baling-machine, of a compression-roller, a frame carrying the same, a winding-drum, cables or chains connecting the frame to the drum, a weighted cable or chain secured to said frame, a rocking frame connected to the roller-carrying frame, a fluid-pressure cylinder, a piston arranged therein and connected to the rocking frame, a valve for controlling the flow of fluid under pressure to and from the cylinder, a rod connected to the valve and provided with a shoulder, a stop with which said shoulder engages, a spring connected to the rod, a cam on said rod, a lug or finger arranged on the movable frame and serving to engage said cam, an arm connected to the valve-rod, and a projecting lug carried by the frame and adapted to engage said arm as the roller-carrying frame nears the limit of its rearward movement.

18. The combination in a baling-press, of compression members, and means for automatically feeding cores or spools between said compression members.

19. The combination in a baling-machine having a baling-chamber, of a pair of compression members, means for automatically feeding empty cores or spools to the compression-chamber, and means for automatically discharging completed bales from said chamber.

20. In a baling-machine, the combination with compression members, of a frame having grooves leading between said compression members, and means for feeding cores or spools along said grooves.

21. The combination in a baling-machine, of grooved frames, means for feeding cores or spools along said grooves, and a compres-

sion member serving at the completion of each baling operation to feed the filled core or spool to discharge position in said grooves.

22. The combination in a baling-machine, of a baling-chamber, compression members, a core or spool reservoir, and means for feeding single spools therefrom to the baling-chamber.

23. The combination in a baling-press, of compression members forming a baling-chamber, a core or spool reservoir, and means under the control of one of said compression members for automatically feeding single cores or spools from the reservoir to the baling-chamber.

24. The combination with a frame, of a compression-roller, a slidable carrier therefor, a core-feeding frame, and an arm secured to said frame and arranged in the path of movement of the carrier.

25. The combination in a baling-machine, of compression members forming a baling-chamber, a movable frame carrying one of said compression members, a core or spool reservoir, a rocking frame having one end in the path of movement of the movable frame, and yieldable fingers carried by the rocking frame and serving to engage successive cores as they are fed to the baling-chamber.

26. In a baling-machine, a continuously-operable means for compressing loose material into a bat or web, an intermittently-operable means for pressing the bat into the form of a cylindrical bale, means for automatically feeding fresh cores to the baling-chamber, and means for automatically discharging filled cores from said chamber.

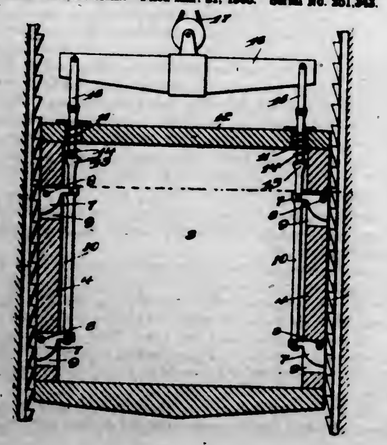
809,284. **RAIL-JOINT.** ALVIN W. CROSMANN and LOGAN L. COMBS, Hickory, Pa. Filed Apr. 27, 1905. Serial No. 257,614.

Claim.—1. A rail-chair comprising an apertured base-plate having rail-engaging means at one edge; a splice-bar supported on the chair, and engaging the opposite side of the rails; lugs extending from the splice-bar, and entering the apertures in the base-plate; and means for securing the splice-bar against lateral displacement.

2. A rail-chair comprising an apertured base-plate having rail-engaging means at one edge, and a key-seat at its opposite edge; a splice-bar supported on the chair; lugs extending from the splice-bar, and entering the apertures in the base-plate; and a key driven into the seat, and engaging the outer edge of the splice-bar, to prevent lateral displacement thereof.

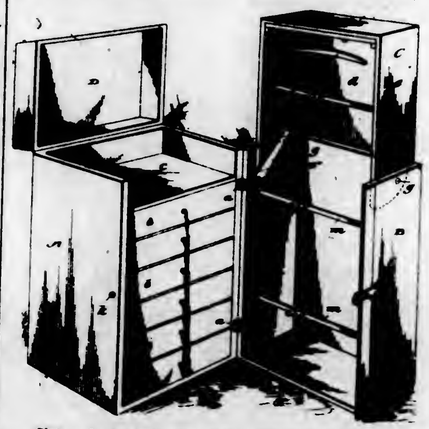
3. A rail-chair comprising an apertured base-plate having rail-engaging means at one edge, and a key-seat at its opposite edge; a splice-bar supported on the chair, and having projections overhanging the key-seat; and a key driven into the seat under said projections, and engaging the outer edge of the splice-bar, to prevent lateral displacement thereof.

809,285. **SAFETY DEVICE FOR ELEVATORS.** JOHN R. CONLEY, Oakland, Kans. Filed Mar. 21, 1905. Serial No. 251,343.



Claim.—In a safety device for elevators the combination of an elevator-shaft, vertical toothed rails arranged in said shaft at opposite sides thereof, a cage, the safety-catches 7 pivoted at opposite sides of the cage, a horizontal bar at the upper portion of the cage and having vertical openings therethrough, the draw-bars 10 arranged at opposite sides of the cage and pivotally connected with the inner ends of the safety-catches, the shoulders 13 pivoted upon said draw-bars, the cross-head 16, the links 15 connecting the upper extremities of the draw-bars 10 and the cross-head 16, the cable 17 connected with the cross-head 16, and the springs 14 coacting with the draw-bars 10 and bearing against the shoulders thereof and normally tending to force the safety-catches into engagement with the toothed rails aforesaid.

809,286. **TRUNK.** HERMAN DAVIS, New Orleans, La. Filed Oct. 3, 1905. Serial No. 281,131.



Claim.—1. A trunk comprising a body-section open at its upper end and having a shelf arranged adjacent to said end, a second body-section hinged to that first mentioned and open at its upper end, a vertically-swinging section hinged to the second-mentioned body-section and arranged when in an upright position to form an upward continuation thereof, and also arranged when in a horizontal position to rest on the shelf of the first-mentioned body-section, and an end-closure section hinged to the back wall of the first-mentioned body-section and arranged when closed to rest over the vertically-swinging section.

2. A trunk comprising a body-section open at its upper end and having a shelf arranged adjacent to said end, a vertical series of slidable drawers arranged in the body-section below the shelf thereof, a second body-section hinged to that first mentioned and open at its upper end, a vertically-swinging section hinged to the second-mentioned body-section and arranged when in an upright position to form an upward continuation thereof and also arranged when in a horizontal position to rest on the shelf of the first-mentioned body-section, suitable means for detachably fastening the said vertically-swinging section in its upright position, means carried by said section for hanging garments in the same and the second-mentioned body-section, means on said sections for retaining garments therein, and an end-closure section hinged to the back wall of the first-mentioned body-section and arranged when closed to rest over the vertically-swinging section.

3. A trunk comprising body-sections hinged together; one of said sections being open at its upper end, and a vertically-swinging section hinged to the last-mentioned body-section and arranged when in an upright position to form an upward continuation thereof, and also arranged to be swung down into a horizontal position and on the other body-section.

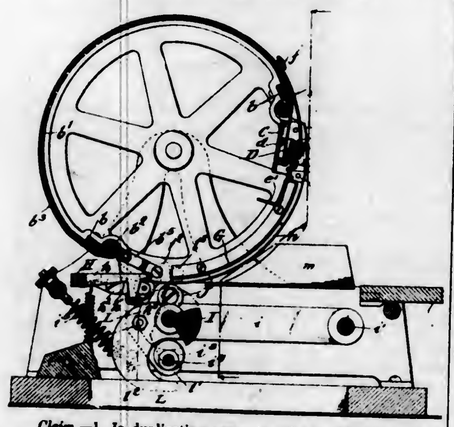
4. A trunk comprising body-sections hinged together; one of said sections being open at its upper end, a vertically-swinging section hinged to the last-mentioned body-section and arranged when in an upright position to form an upward continuation thereof, and an end-closure section hinged to the back wall of the other body-section and arranged when closed to rest over the said vertically-swinging section.

5. A trunk comprising body-sections hinged together; one of said sections being open at its upper end, and an adjustable section carried by the last-mentioned body-section and arranged when in an upright position to form an upward continuation thereof, and also arranged when in a horizontal position to rest on the other body-section.

6. A trunk comprising body-sections hinged together; one of said sections being open at its upper end, an adjustable section carried by the last-mentioned body-section and arranged to be placed in an upright position to form an upward continuation thereof and also arranged to be placed in a horizontal position and on the other body-section, and an end-closure section carried by such other body-section and arranged when closed to rest over the said adjustable section.

7. A trunk comprising body-sections hinged together; one of said sections being open at its upper end, an adjustable section carried by the last-mentioned body-section and arranged to be placed in an upright position to form an upward continuation thereof and also arranged to be placed in a horizontal position and on the other body-section, an end-closure section carried by such other body-section and arranged when closed to rest over the adjustable section, and means on the adjustable section coöperating with means on the body-section by which it is carried for detachably securing the adjustable section in its upright position.

809,287. **DUPLICATING APPARATUS.** ALBERT B. DICK, Lake Forest, Ill., assignor to A. B. Dick Company, Chicago, Ill., a Corporation of Illinois. Filed Feb. 4, 1905. Serial No. 244,136.



Claim.—1. In duplicating apparatus, the combination with a movable drum and an underlying pressure-roller, of means carried by said drum for flattening an impression-sheet in advance of the passage of the same between said drum and roller, substantially as set forth.

2. In duplicating apparatus, the combination with a movable drum and an underlying pressure-roller, of members mounted within the drum, at that point not covered by the stencil-sheet thereon, for coacting with an impression-sheet in advance of the passage of the same between said drum and roller, substantially as set forth.

3. In duplicating apparatus, the combination with a movable drum and an underlying pressure-roller, of means for passing an impression-sheet between said drum and roller and wings carried by said drum and extending adjacent to the path of such impression-sheet, substantially as set forth.

4. In duplicating apparatus, the combination with a movable drum comprising heads and a stencil-carrier, of wings extending inwardly from the inner faces of said drum-heads and adapted to coact with a sheet in advance of the passage thereof between said drum and roller, substantially as set forth.

5. In duplicating apparatus, the combination with a movable drum, of an underlying pressure-roller movable to operative and inoperative positions relatively to said drum, a lock positively coacting with said roller and means operated by said drum for actuating said lock to hold said roller in inoperative position, substantially as set forth.

6. In duplicating apparatus, the combination with a movable drum and an underlying pressure-roller movable to operative and inoperative relation to said drum, of means carried by the drum for moving said roller to inoperative position, and a lock operated by said drum for maintaining said roller in such position, substantially as set forth.

7. In duplicating apparatus, the combination with a drum and an underlying pressure-roller mounted on swinging arms and movable to operative and inoperative relation to said drum, of a lock for maintaining said pressure-roller in inoperative position said lock including a lever mounted upon one of said arms, and means carried by said drum for moving said lever to locking and unlocking positions, substantially as set forth.

8. In duplicating apparatus, the combination with a movable drum and an underlying pressure-roller mounted upon hinged arms, of a cam carried by said drum and operating to throw said pressure-roller to inoperative position, a locking device for said pressure-roller, and means carried by said drum for operating said locking device, substantially as set forth.

9. In duplicating apparatus, the combination with a movable drum, of an underlying pressure-roller movable to operative and inoperative relation to said drum, means carried by said drum for moving said roller to inoperative position, and a lock for said pressure-roller having a member projecting into the line of travel of a projection upon said drum, substantially as set forth.

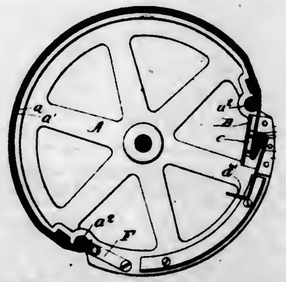
10. In duplicating apparatus, the combination with a movable drum, of an underlying pressure-roller mounted in hinged arms spring-pressed toward said drum, mechanism intermediate of said roller and drum for depressing the former, locking-levers carried by said hinged arms and adapted to lock said pressure-roller in inoperative position, and means carried by said drum for operating said levers, substantially as set forth.

11. In duplicating apparatus, the combination with a drum and a stencil and an attaching device carried thereby, of a stencil-protecting plate detachably secured to said drum independently of said device, said plate coacting with said stencil, substantially as set forth.

12. In duplicating apparatus, the combination with a drum and a stencil-attaching device carried thereby, of a detachable stencil-protecting plate independent of said device, and means carried by said drum and coacting with said plate at either edge thereof to maintain said plate in position, substantially as set forth.

13. In duplicating apparatus, the combination with a drum and a stencil-attaching device carried thereby, of a detachable stencil-protecting plate independent of said device, and latches carried by said drum for securing said plate in position, substantially as set forth.

809,288. **DUPLICATING APPARATUS.** ALBERT B. DICK, Lake Forest, Ill., assignor to A. B. Dick Company, Chicago, Ill., a Corporation of Illinois. Filed Feb. 4, 1905. Serial No. 244,139.



Claim.—1. In duplicating apparatus, the combination with a drum and a stencil-sheet, of coacting parts one supported on said drum and the other supported on said sheet and one of which is movable relatively to its support, said parts being arranged to secure said sheet in position on said drum by a forward and reverse movement of the sheet relatively to the drum, substantially as set forth.

2. In duplicating apparatus, the combination with a drum and a part secured to said drum and adapted to move therewith, said part having a substantially flat and uniform surface, of a stencil-sheet the forward end whereof is movable relatively to the body portion of the sheet and is brought into coaction with said part by a forward move-

ment past said part and then a rearward movement relatively thereto, substantially as set forth.

3. In duplicating apparatus, the combination with a movable drum, of a part secured thereto, and a stencil-sheet having at one end a portion extending back adjacent to the body portion thereof and movable relatively to such body portion, said sheet being brought into automatic securing relation to said drum by relative movement thereof carrying said end of the sheet past said part on the drum and succeeding movement in the opposite direction, substantially as set forth.

4. In duplicating apparatus, the combination with a drum, of a part secured thereto and moving therewith, and a stencil-sheet having a folded elastic end coacting with said part, substantially as set forth.

5. In duplicating apparatus, the combination with a drum, of two parts secured thereto and moving therewith, a stencil-sheet and means carried thereby for securing said sheet in position upon passing the forward end thereof between said parts, substantially as set forth.

6. In duplicating apparatus, the combination with a drum, of a part secured thereto and moving therewith, a stop, a stencil-sheet and means carried thereby for securing said sheet in position upon movement of the same toward and from said stop and in coöperative relation to said part, substantially as set forth.

7. In duplicating apparatus, the combination with a drum, of two parts secured thereto and moving therewith, a stencil-sheet and means carried thereby for securing said sheet in position upon said drum upon the movement of said sheet past one of said parts and its return movement, leaving a portion of said sheet between said part and the other part, substantially as set forth.

8. In duplicating apparatus, the combination with a drum, of three parts carried thereby and movable therewith, a stencil-sheet, and means for securing the same in position upon said drum by passing the end thereof forward between two of said parts and then rearward, leaving a portion of said sheet between one of said parts and the third part, substantially as set forth.

9. In duplicating apparatus, the combination with a drum, of a part moving therewith, and a stencil-sheet having a part elastically connected thereto but extending outwardly and backwardly from the end thereof and adapted to coact with said part upon said drum upon forward and rearward movement of said sheet relatively thereto, substantially as set forth.

10. In duplicating apparatus, the combination with a drum, of a part moving therewith, a stencil-sheet having a part elastically connected thereto but extending outwardly and backwardly from the end thereof and entirely free from the sheet except at said end, said part of the stencil-sheet coacting with said part moving with the drum to secure the sheet upon the drum, substantially as set forth.

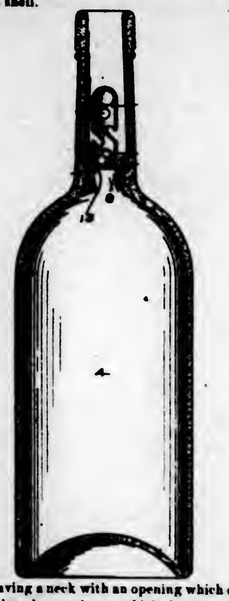
11. In duplicating apparatus, the combination with a drum having a shelf-plate and a locking-plate, of a stencil-sheet having a folded forward end adapted to pass between said plates and to coact automatically with said locking-plate, by reason of its elasticity, substantially as set forth.

12. In duplicating apparatus, the combination with a shelf-plate, a locking-plate and a stop-plate, of a stencil-sheet having a folded forward end adapted to be passed between said shelf-plate and locking-plate and to automatically coact with said locking-plate, by reason of its elasticity, upon reverse movement of said sheet, the fold thereof passing between said locking-plate and said stop-plate, substantially as set forth.

809,289. NON-REFILLABLE BOTTLE. WILLIAM J. DOLAN and FRANK H. BOSSHARDT, Indianapolis, Ind. Filed May 20, 1905. Serial No. 261,004.

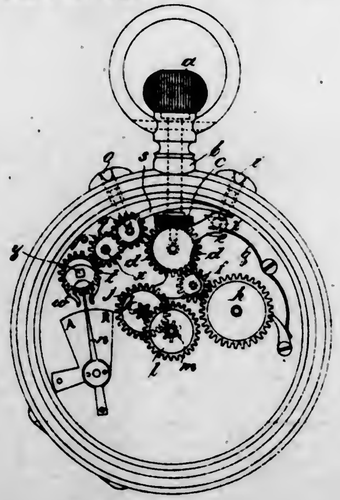
Claim.—1. The combination with a bottle having a groove within its neck, of a shell closed at one end and introduced into the bottle and having its other end resting in said groove, said latter end being expansible to prevent the withdrawal of the shell, said shell having perforations and additional slotted openings through its walls and a valve-seat at its open end, and a ball-valve within said shell forming a closure with said seat against entrance to the bottle.

2. A bottle having a neck with an opening which increases in diameter as it extends into the bottle and terminating with a shoulder forming an opening of less diameter than the mouth of the bottle, a metal shell closed at one end and having a flange at its opposite end at right angles to the body of the shell and resting upon the shoulder of the bottle, said flange being bent up approximately parallel with the body of the shell for introduction into the bottle and afterward flared to prevent withdrawal, said shell having openings through its walls and said shell having its lower end restricted in diameter, and a ball within the shell making its seat upon the restricted portions at the mouth of the shell.



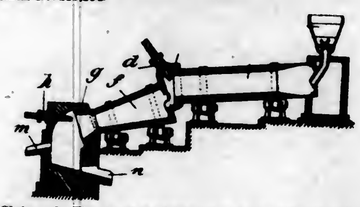
3. A bottle having a neck with an opening which expands downwardly to a shoulder, the opening at which shoulder is of less diameter than the mouth of the bottle, an annular flange between the shoulder and the mouth of the bottle, a metal shell introduced into the neck of the bottle, said shell being closed at one end and having an outwardly-extending flange at its other end, said flange resting upon said shoulder and forming the support for the shell, said flange having an upwardly-extended portion engaging the flange in the neck of the bottle, said shell having oblique slots in its opposite walls, and perforations between said slots and the upper end of the shell, a valve-seat in the lower end of the shell, and a ball placed loosely within the shell and operating with the valve-seat to prevent ingress to the bottle.

809,290. WATCH. ADOLF PEHLCKE, Charlottenburg, Germany. Filed June 3, 1904. Serial No. 211,616.



Claim.—In a watch, the combination comprising the watchcase, a winding-stem, a toothed wheel *e* arranged upon this winding-stem, the toothed wheel *d* engaging the said toothed wheel *c*, a turnable coupling-plate *e* arranged on the shaft of said toothed wheel *d*, a toothed wheel *f* arranged at said coupling-plate *e*, a turnable coupling-lever, a toothed wheel *g* arranged on said coupling-lever, two toothed wheels *p t* driven by said toothed wheel *g*, a horseshoe-shaped body secured to said toothed wheel *t* for operating the regulating-hand of the watch, a setting mechanism for setting the watch, a winding-wheel *h*, a push-button *i* for alternate coupling the wheel *f* with said setting mechanism respectively the winding-wheel, a second push-button for operating simultaneously by aid of said coupling-lever the regulating-hand and the setting mechanism of the watch, substantially as described.

809,291. ART OF MANUFACTURING IRON OR STEEL. EMIL FLEISCHER, Dresden-Strehlen, Germany, assignor to Jacob Eduard Goldschmid, Frankfort-on-the-Main, Germany. Filed July 26, 1904. Serial No. 218,264.



Claim.—1. The art of producing iron or steel direct, which consists in subjecting the ore to a continuous transversely-rolling and a continuous forwardly-progressive motion, and simultaneously acting upon it by consecutive gas-flames, the first of which is a reducing-flame.

2. The art of producing iron or steel direct, which consists in subjecting the ore, in the presence of fluxes, to a continuous transversely-rolling and a continuous forwardly-progressive motion, and simultaneously acting upon it by consecutive gas-flames, the first of which is a reducing-flame.

3. The art of producing iron or steel direct, which consists in subjecting the ore, in the presence of fluxes and pulverized carbon, to a continuous transversely-rolling and a continuous forwardly-progressive motion, and simultaneously acting upon it by consecutive gas-flames, the first of which is a reducing-flame.

4. The art of producing iron or steel direct, which consists in subjecting the charge to a continuous transversely-rolling and a continuous forwardly-progressing motion, and simultaneously acting upon the charge, at the initial stage of its forward travel, by a reducing-flame, and, at the terminal stage of its travel, by a melting-flame.

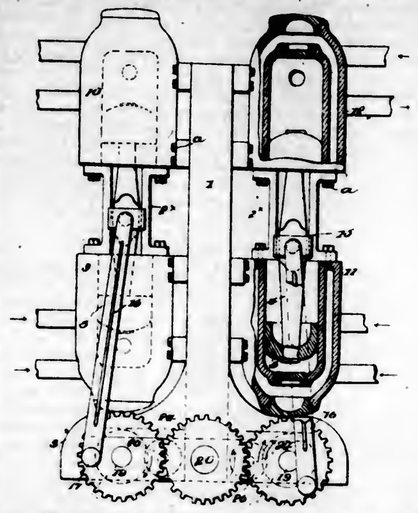
5. The art of producing iron or steel direct, which consists in subjecting the charge to a continuous transversely-rolling and a continuous forwardly-progressing motion, and simultaneously acting upon the charge, at the initial stage of its forward travel, by a strongly-reducing flame, and at the terminal stage of its travel, to a substantially neutral melting-flame.

809,292. GAS-ENGINE. WILLIAM T. FOX, Rochester, N. Y. Filed Aug. 17, 1904. Serial No. 221,061.

Claim.—1. In a gas-engine, the cylinders having each a piston and arranged in four pairs, a rigid rod connecting the pistons of each pair, two crank-shafts one for each double pair, a main or driving shaft operatively connected to the crank-shafts, and means for successively exploding gas in the cylinders to drive said main shaft at every quarter-rotation thereof.

2. In a gas-engine, the cylinders having each a piston and arranged in four pairs, a rigid rod connecting the pistons of each pair, two crank-shafts one for each double pair, a main or driving shaft operatively connected to the crank-shafts, and means for successively exploding gas in the cylinders to drive said main shaft at every quarter-rotation thereof, the several shafts being parallel and operatively connected by gears.

3. In a gas-engine, the cylinders having each a piston and arranged in four pairs, a rigid rod connecting the pistons of each pair, two crank-shafts one for each double pair, a main or driving shaft operatively connected to the crank-shafts, and means for successively exploding gas in the cylinders to drive said main shaft at every quarter-rotation thereof, the several shafts being parallel and operatively connected by gears, and the valve-actuating cam-shafts situated between and parallel to the said crank-shafts.



4. In a gas-engine, the cylinders having each a piston and arranged in four pairs, a rigid rod connecting the pistons of each pair, two crank-shafts one for each double pair, a main or driving shaft operatively connected to the crank-shafts, and means for successively exploding gas in the cylinders to drive said main shaft at every quarter-rotation thereof, the several shafts being parallel and operatively connected by gears situated at both ends of the shafts.

5. In a gas-engine, the cylinders having each a piston and arranged in four pairs, a rigid rod connecting the pistons of each pair, two crank-shafts one for each double pair, a main driving-shaft operatively connected to the crank-shafts, and means for successively exploding gas in the cylinders to drive said main shaft at every quarter-rotation thereof the several shafts being parallel and operatively connected by gears, and the valve-actuating cam-shafts situated between and parallel to the said crank-shafts.

6. In a gas-engine, the cylinders having each a piston and arranged in four pairs, a rigid rod connecting the pistons of each pair, two crank-shafts one for each double pair, a main driving-shaft operatively connected to the crank-shafts, and means for successively exploding gas in the cylinders to drive said main shaft at every quarter-rotation thereof, the several shafts being parallel and operatively connected by gears, and the valve-actuating cam-shafts situated between and parallel to the said crank-shafts, said cam-shafts having gears fixed thereon and driven by pinions on the crank-shafts, all of said shafts being situated in approximately the same plane.

7. In a gas-engine, the cylinders having each a piston and arranged in four pairs, a rigid rod connecting the pistons of each pair, two crank-shafts one for each double pair, a main driving-shaft operatively connected to the crank-shafts, and means for successively exploding gas in the cylinders to drive said main shaft at every quarter-rotation thereof, the several shafts being parallel and operatively connected by gears, and the valve-actuating cam-shafts situated between and parallel to the said crank-shafts, said cam-shafts having gears fixed thereon and driven by pinions on the crank-shafts, all of said shafts being situated in approximately the same plane and in the base below the cylinders.

8. In a gas-engine, the cylinders having each a piston and arranged in four pairs, a rigid rod connecting the pistons of each pair, two crank-shafts one for each double pair, a main or driving shaft operatively connected to the crank-shafts, and means for successively exploding gas in the cylinders to drive said main shaft at every quarter-rotation thereof, the several shafts being parallel and operatively connected by gears, and the valve-actuating cam-shafts sit-

uated between and parallel to the said crank-shafts, said cam-shafts having gears fixed thereon and driven by pinions on the crank-shafts, all of said shafts being situated in approximately the same plane and in the base below the cylinders, and a post rising from the base, the pairs of cylinders being fixed to opposite sides of said post.

9. In a gas-engine, the base, the central post, and the several cylinders separately fixed to the post on opposite sides thereof and detachable singly therefrom.

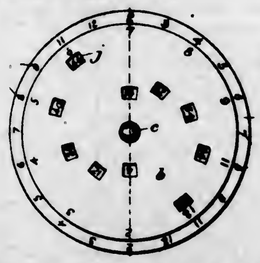
10. In a gas-engine, the base, the central post, the several cylinders separately fixed to the post on opposite sides thereof, and piston-rod guides detachably fixed to cylinders having pistons with a rigid rod common to the pistons of two cylinders.

11. In a gas-engine, the base having the central post, the cylinders arranged in pairs, the pistons, piston-actuating shafts, and the valve-actuating rods, all said shafts being situated in the base and said rods situated between the cylinders.

809,293. GAME APPARATUS. ALBERT FRIEDENTHAL, Oakland, Cal. Filed Oct. 26, 1904. Serial No. 229,063.

Claim.—In a game apparatus of the kind described, a decahedron having its faces marked to indicate different values of different species, each face being quadrangular in shape, and the peripherial edge of the decahedron zigzag as set forth.

809,294. CALCULATOR. SPEED S. FRY, Breckenridge, Colo. Filed Mar. 27, 1905. Serial No. 252,369.

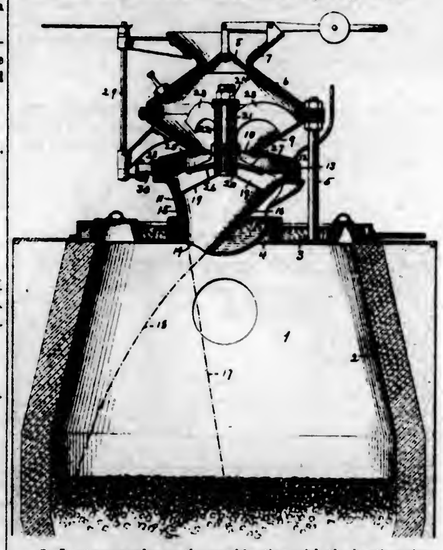


Claim.—In a device of the character described, a disk having a series of numbers in duplicate around its edge, of different identities, each number having arranged therebeneath on a radial line, series of numbers of the same identity, a second disk pivoted to the first-named disk, said disks having series of reversely and spirally arranged apertures, said disk having series of numbers around its edge of different identities but coinciding with the identities of the series of the first-named disk, said series of the second-named disk not being in duplicate, coinciding series of the disks and one of the series of the apertures all acting in conjunction one with the other.

809,295. GAS-PRODUCER. JUNIUS R. GREENE, Worcester, Mass., assignor to Morgan Construction Company, Worcester, Mass., a Corporation of Massachusetts. Filed July 10, 1903. Serial No. 164,994.

Claim.—1. In a gas-producer, the combination with the heating-chamber having an opening at its top for the admission of fuel, of a fuel-reservoir placed above said opening and having an opening in its bottom for the delivery of fuel to a distributer, a distributer between the opening in the heating-chamber and the opening in the reservoir, said distributer consisting of a rotating shell smaller at its lower than at its upper end, with an opening at its upper end larger than the delivery-opening of said reservoir and concentric with its axis of rotation, and with an opening at its lower end eccentric with its axis of rotation, and a disk inclosed in said distributer having its diameter larger than the diameter of the delivery-opening in said reservoir, with an annular space around said disk for the passage of fuel.

2. In a gas-producer, the combination with the heating-chamber having an opening at its top for the admission of fuel, of a fuel-reservoir placed above said opening, said reservoir having a hopper-shaped bottom with a concentric opening therein for the delivery of fuel to a distributer, a distributer between the opening in the heating-chamber and the delivery-opening of said reservoir, said distributer consisting of a rotating shell smaller at its lower than at its upper end, with an opening at its upper end larger than the delivery-opening of said reservoir and concentric with its axis of rotation, and with an opening at its lower end eccentric with its axis of rotation, and a disk inclosed in said distributer, having its diameter larger than the diameter of the delivery-opening in said reservoir, with an annular space around said disk for the passage of fuel.



3. In a gas-producer, the combination with the heating-chamber having an opening at its top for the admission of fuel, of a rotating fuel-distributer placed above said heating-chamber and consisting of a shell, with a passage therethrough for fuel, said distributer having an opening at its upper end concentric with its axis of rotation for the admission of fuel, and an opening at its lower end eccentric to its axis of rotation for the delivery of fuel, with the sides of said distributer having a varying inclination to a vertical plane, whereby the fuel in passing through said distributer is projected into the heating-chamber at different angles, a disk inclosed in said distributer, with an annular space around it for the downward passage of fuel, and means for delivering fuel to said distributer upon the central portion of said disk, substantially as described.

4. In a gas-producer, the combination with a heating-chamber having a top plate provided with an opening for fuel, of a rotating fuel-distributer above said top plate, said distributer consisting of a shell having a passage therethrough for fuel, and having a delivery-opening at its lower end for the delivery of fuel to the heating-chamber, a concentric disk inclosed in said distributer near its upper end, with an annular space between said disk and the wall of the distributer, and means for supplying fuel to the central section of said disk.

5. In a gas-producer, the combination with a heating-chamber having an opening at its top for the admission of fuel, of a distributer above said opening, consisting of a rotating shell with its lower end the smaller and provided with an opening eccentric to its axis of rotation for the delivery of fuel to the heating-chamber, a disk carried by said distributer, with an annular space between said disk and the inner wall of said distributer, substantially as described.

6. In a gas-producer, the combination with a heating-chamber having an opening at its top for the admission of fuel, of a fuel-distributer above said opening and consisting of a rotating shell having a passage therethrough, with the lower end of said shell the smaller and provided with an opening eccentric to its axis of rotation, a disk carried by said shell, with its upper surface slightly inclined from its center downward, and having an annular space between said disk and the inner wall of said distributer, substantially as described.

7. In a gas-producer, the combination with a heating-chamber having an opening for the admission of fuel, and a fuel-reservoir

placed above said opening and having an opening in its bottom for the delivery of fuel to a distributer, of a fuel-distributer between said heating-chamber and said reservoir, said fuel-distributer having an annular admission-opening for the admission of fuel of greater diameter than the opening in the bottom of said reservoir, and concentric with its axis of rotation, with the inner wall of said distributer at a varying inclination to a vertical plane, and a delivery-opening eccentric with its axis of rotation.

8. In a gas-producer, the combination with a heating-chamber, having an opening in its top for the admission of fuel, and a fuel-reservoir placed above said opening and having an opening in its bottom for the delivery of fuel to a distributer, of a fuel-distributer between said heating-chamber and said reservoir, said fuel-distributer having an annular eccentric admission-opening for the admission of fuel of greater diameter than the opening in the bottom of said reservoir, means for conducting the fuel from said opening in the bottom of said reservoir to said annular admission-opening, and an eccentric delivery-opening at the bottom of said distributer.

9. In a gas-producer, the combination with the heating-chamber, of a fuel-distributer, consisting of a rotating shell placed above the heating-chamber with the lower end of said shell the smaller, a central hub in said shell, arms connecting said shell and said hub, a disk supported by said hub concentrically with said shell, with an annular space between said disk and said shell for the passage of fuel, a shaft held in said hub, a journal-bearing above said distributer for said shaft, and means for supplying fuel to said distributer, substantially as described.

10. In a gas-producer, the combination of a heating-chamber, having an opening at its top for the admission of fuel, a rotating hollow fuel-distributer above said opening with its upper end concentric and with its lower end eccentric with said fuel-opening, means for rotating said distributer, means for closing the central section of the fuel-passage at the upper end of said distributer whereby an annular fuel-passage is formed at the upper end of the distributer, and means for supplying fuel to said distributer, substantially as described.

11. In a gas-producer, the combination with a heating-chamber having an opening at the top for the admission of fuel, of a rotating fuel-distributer placed above said opening, said distributer having a concentric annular passage at its upper end and an eccentric delivery-opening at its lower end, means for rotating said distributer, a fuel-reservoir above said distributer having a hopper-shaped bottom with a delivery-opening therein smaller than the annular passage in said distributer, substantially as described.

12. In a gas-producer, the combination with a heating-chamber having an opening in its top for the admission of fuel, of a fuel-reservoir placed above said opening and having a hopper-shaped bottom provided with a concentric opening for the delivery of fuel, a central hub inclosed in said reservoir, arms connecting said hub with the wall of the reservoir, a shaft journaled in said hub, a hub attached to the lower end of said shaft, arms connecting said second hub with a rotating shell having its upper end concentric with said shaft and having its lower end inclosed in the fuel-opening of the heating-chamber and provided with an opening eccentric to its axis of rotation and a disk inclosed in said distributer with an annular space between said disk and the inner wall of said distributer, and with the diameter of said disk greater than the delivery-opening in said reservoir, substantially as described.

809,296. DRILL-CHUCK. CHARLES GORDON, Milwaukee, Wis. Filed June 9, 1902. Serial No. 110,710.

Claim.—1. In a drill-chuck, the combination of a shank, a body portion, movable centering-jaws, movable driving-dogs carried by the body portion independently of the centering-jaws, and means for automatically operating said dogs and jaws.

2. In a drill-chuck, the combination of a shank, a body portion having fixed projecting arms, oppositely-disposed cooperating centering-jaws located and movable between said arms, driving-dogs carried by said arms independently of the centering-jaw, means for operating the centering-jaws, and separate means for operating the driving-dogs.

3. In a drill-chuck, the combination of a body portion having a driving-shank on one end and fixed depending arms on the opposite end, a pair of interlocking, movable, centering-jaws, located between said arms, drill-driving dogs sliding in bearings carried by the depending arms, springs carried by the said arms, and acting to move the dogs inward, means carried by the arms to move the said dogs outward and independent means connected with the chuck-body that operates the centering-jaws.

4. In a drill-chuck, the combination of a body portion having a driving-shank on one end and fixed depending arms on the opposite end, a pair of interlocking, movable centering-jaws located between said arms, said jaws having their outer edges inclined and grooved, a slotted plate engaging with the said inclined grooved outer edges of the jaws and adapted to move longitudinally on the depending arms, means for moving the plate longitudinally and independent means for holding the drill against rotation, relative to the chuck.

5. In a drill-chuck, the combination of a body portion having a driving-shank on one end and fixed depending arms on the opposite end, a pair of interlocking, movable, centering-jaws located between said arms, said jaws having their outer edges inclined, a slotted plate engaging with the said inclined outer edges of the jaws, and adapted to move longitudinally on the depending arms and positively control the movement of said jaws, a plate above the body portion of the chuck, movable on the chuck-shank, and connected with the lower slotted plate and a spring interposed between the upper plate and the chuck-body.

6. In a drill-chuck the combination of a body portion having a driving-shank on one end, fixed depending arms on the opposite end, and a collar on the lower part of the body portion, a pair of interlocking, centering-jaws, located between said arms, said jaws having their outer edges inclined, a slotted plate engaging with the inclined outer edges of the jaws and adapted to move longitudinally on the said arms, a plate above the body portion of the chuck, movable on the driving-shank, connections between the two plates and a spring between the upper plate and the collar.

7. In a drill-chuck, the combination of a body portion having a driving-shank on one end, fixed depending arms on the opposite end, centering-jaws located between the arms, drill-holding dogs adapted to slide in transverse diametrically-disposed openings through the arms, inclined slots or shoulders on the dogs, springs operating to move the dogs inward, plungers moving through longitudinal openings, in the arms and body portion, said plungers having angular ends adapted to engage with the angular slots or shoulders on the dogs, and means for moving the plungers longitudinally to separate the dogs.

809,297. AXLE-TRUSS. CHARLES M. HASSER, South Bend, Ind. Filed May 31, 1905. Serial No. 263,164.

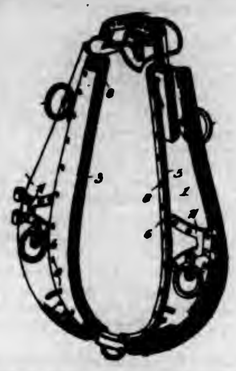
Claim.—1. In combination, an axle-truss having a slot adjacent to each of its ends, axle-skeins having two shoulders, said skeins having their under sides between said shoulders flattened, the inner one of said shoulders being cut away at the under side, lugs located upon the flattened portion of said skeins, one of said lugs being located at the portion where the inner shoulder is cut away, the other lug being located adjacent to said first-mentioned lug, guides at each side of said flattened portion, the said lugs being adapted, respectively, to enter the slot in the said axle-truss and to form end abutments therefor, and means for retaining the said axle-truss in rigid engagement with the said axle-skeins.

2. An axle-truss provided with a slot in each end thereof, axle-skeins having a flattened under side, guideways at each side of said flattened portion, lugs located within said flattened portion, said lugs being so located that they will be in a position to enter the said slot in the ends of the axle-truss and form an abutment for the end of said axle-truss, and a binding-clip located between said lugs and adapted to retain the truss and the skeins in rigid engagement.

809,298. HORSE-COLLAR. GEORGE W. HAHN, Mansfield, Ill. Filed May 17, 1904. Serial No. 208,489.

Claim.—1. A horse-collar, comprising thin metallic sides forming a complete front for the collar, complete side pads having inner

and outer flexible walls and provided at their side edges with seams, the inner walls of the pads being fitted against the inner faces of the metallic sides, and means independent of the seams of the side pads for securing the latter to the metallic sides, whereby the side pads are adapted to be removed therefrom without separating the walls of the said pads.



2. A horse-collar, comprising thin metallic sides curved in cross-section and having their front and rear longitudinal edges extended in opposite directions, and complete side pads arranged along the inner faces of the metallic sides and provided at their front and rear edges with flexible attachment portions or flanges formed by extending the walls of the pads beyond the seams thereof and fitted against the front and rear edges of the metal sides and secured to the same, substantially as described.

3. A horse-collar, comprising metallic sides curved in cross-section and having rearwardly-curved rear edges and forwardly-curved front edges, the latter being partially rolled to present inner convexed faces, and complete side pads arranged along the inner faces of the metallic sides and provided at their front and rear edges with flexible flanges or attachment portions fitted against and conforming to the configuration of the front and rear curved edges of the sides and secured to the same, said flexible flanges or attachment portions being formed by extensions of the outer or rear walls of the pads, substantially as described.

4. A horse-collar, comprising thin metallic sides forming a complete front for the collar, complete side pads provided with inner and outer walls and having seams connecting the walls at the side edges of the pads, and means for detachably securing the side pads to the metallic sides at the inner and outer edges of the former and at points beyond the seams thereof.

809,299. **MANUFACTURE OF BOTTLE-ENVELOPS.** CHRISTIAN B. B. HEBER and GUSTAV A. H. SCHULTZ, Bremen, Germany. Filed July 8, 1903. Serial No. 164,726.

Claim.—The method of making bottle-wrappers from fluted cardboard having a plain backing, which consists in wrapping a strip of such cardboard around the body of a bottle or around a smooth core of like form with the plain backing outside and the fluting lengthwise of the bottle-core, steaming that portion of the cardboard which is to form the neck of the wrapper, shaping said neck by pressure, gathering and tying the end of the neck and uniting the overlapping sides of the cardboard, whereby said board will be evenly creased all around at the neck by reason of the pressure on the fluted board which starts the creases between adjacent flutings attached to the backing and causes the creases to lie parallel to the axis of the wrapper.

809,300. **SWITCH-PLUG WITH ELECTRICAL FUSE.** ALEXANDER HEPNER and KURT DENNER, Berlin, Germany. Filed July 20, 1904. Serial No. 217,207.

Claim.—1. In a fuse-plug for electric circuits, the combination with an insulating plug-body, of two contact-bodies fixed to said plug-body, through which contact-bodies the current enters and leaves the plug, a plurality of fuses within said plug-body in fixed position to the same, and electrically connected with one of their ends to one of said contact-bodies, and a movable member for connecting *serviatim* the other ends of the fuses with the other contact-body, substantially as described and for the purpose set forth.

2. In a fuse-plug for electric circuits, the combination with an insulating plug-body, of two contact-bodies fixed to said plug-body, through which contact-bodies the current enters and leaves the plug, a plurality of fuses within said plug-body in fixed position to the same, and electrically connected with one of their ends to one of said contact-bodies, and a member movable around its axis for connecting *serviatim* the other ends of the fuses with the other contact-body, substantially as described and for the purpose set forth.

3. In a fuse-plug for electric circuits, the combination with an insulating plug-body, of two outside contact-bodies fixed to said plug-body, through which contact-bodies the current enters and leaves the plug, a plurality of fuses within said plug-body in fixed position to the same, and electrically connected with one of their ends to one of said contact-bodies, a plate of insulated material, pairs of contact-pieces situated in said plate, one of the contact-pieces of each pair being electrically connected to the other end of one of the fuses, the other contact-piece of each pair being electrically connected to the second contact-body, and means for electrically connecting in turn the contact-pieces of each pair to each other, substantially as described and for the purpose set forth.

4. In a fuse-plug for electric circuits, the combination with an insulating plug-body, of two outside contact-bodies fixed to said plug-body, through which contact-bodies the current enters and leaves the plug, a plurality of fuses within said plug-body in fixed position to the same, and electrically connected with one of their ends to one of said contact-bodies, a plate of insulated material, pairs of contact-pieces situated in said plate, one of the contact-pieces of each pair being electrically connected to the other end of one of the fuses, the other contact-piece of each pair being electrically connected to the second contact-body, a plate of insulating material with a metallic strip, and means for turning said insulated plate so as to electrically connect the two contact-pieces of in turn each pair to each other, substantially as described and for the purpose set forth.

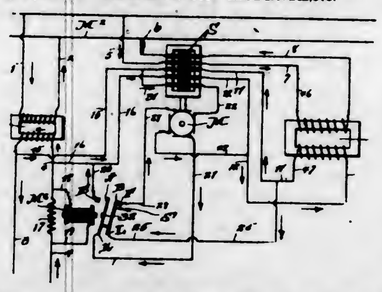
809,301. **ELECTRIC MULTIPLE-FUSE PLUG.** ALEXANDER HEPNER and KURT DENNER, Berlin, Germany. Filed July 20, 1904. Serial No. 217,208.

Claim.—1. In an electric fuse-plug, the combination with a plug-body of two outside contact-bodies, through which the current enters and leaves the plug, a plurality of fuses within said plug-body, one end of each fuse being electrically connected to one of said contact-bodies, means arranged on the outside of the plug and so movable thereon as to electrically connect *serviatim* the other fuse ends with the other outside contact-body, essentially as described and for the purpose set forth.

2. In an electric fuse-plug, the combination with a plug-body of two outside contact-bodies, through which the current enters and leaves the plug, a plurality of fuses within said plug-body, one end of each fuse being electrically connected to one of said contact-bodies, means arranged on the outside of the plug and so movable thereon as to electrically connect successively a certain number of the inside fuses with the other outside contact-body, substantially as described and for the purpose set forth.

3. In an electric fuse-plug, the combination with a plug-body, of two outside contact-bodies, through which the current enters and leaves the plug, a plurality of fuses within said plug-body, one end of each fuse being electrically connected to one of said contact-bodies, partitions for insulating two successive fuses from each other, and a movable ring on the outside of the plug-body, with contact-springs for electrically connecting successively one of the inside fuses with the other outside contact-body, substantially as described and for the purpose set forth.

809,302. **TRANSFORMER CUT-OUT.** JOHN P. HUTHERINGTON, Logansport, Ind. Filed Jan. 27, 1905. Serial No. 242,570.



Claim.—1. In an apparatus of the character described, the combination, of a primary circuit, a secondary circuit, a transformer connected to receive current from said primary circuit and to deliver the transformed current to said secondary circuit, an auxiliary transformer, and means for automatically introducing said auxiliary transformer into the system in parallel with said first transformer, and cutting it out therefrom, said means consisting of devices controlled by variations in the load, substantially as described.

2. In an apparatus of the character described, the combination, of a primary circuit, a secondary circuit, a transformer connected to receive current from said primary circuit, and to deliver the transformed current to said secondary circuit, an auxiliary transformer, and means for automatically introducing said auxiliary transformer into the system in parallel with said first transformer, and cutting it out therefrom, said means consisting of devices connected with the secondary circuit and controlled by variations in the load, substantially as described.

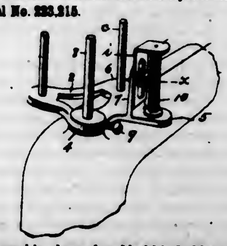
3. In an apparatus of the character described, the combination, of a primary circuit, a secondary circuit, a transformer connected to receive current from said primary circuit and to deliver the transformed current to said secondary circuit, an auxiliary transformer and means for automatically introducing said auxiliary transformer into the system in parallel with said first transformer, said means consisting of a switch, connections from the primary circuit to the auxiliary transformer and from the auxiliary transformer to the secondary circuit controlled by said switch, an actuator for said switch, automatic means for energizing said actuator when the load becomes excessive and automatic means for deenergizing the actuator and stopping the switch after a predetermined amount of movement of the same to cut said auxiliary transformer into the circuit, substantially as described.

4. In an apparatus of the character described, the combination of a primary circuit, a secondary circuit, a transformer connected to receive current from said primary circuit and to deliver the transformed current to said secondary circuit, an auxiliary transformer, and means for automatically introducing said auxiliary transformer into the system in parallel with said first transformer, said means consisting of a switch, connections controlled by said switch, leading from the primary circuit to the auxiliary transformer and from the auxiliary transformer to the secondary circuit, a motor to actuate said switch, magnetic devices interposed in the secondary circuit and adapted to become operative upon an excess of load therein, a circuit adapted to operate the motor and controlled by said magnetic devices, the arrangement being such that said switch will be operated to cut said auxiliary transformer into the system upon an excess of load, substantially as described.

5. In an apparatus of the character described, the combination of a primary circuit, a secondary circuit, a transformer connected to receive current from said primary circuit and to deliver the transformed current to said secondary circuit, an auxiliary transformer and means for automatically introducing said auxiliary transformer into the system in parallel with said first transformer cutting it out therefrom, said means consisting of connections from the primary to said auxiliary transformer and from said auxiliary transformer to the secondary, a switch for controlling said connections, a motor for operating said switch, a magnet interposed in the secondary circuit, an armature carrying electrical connections and contact-points upon its opposite sides and adapted to be actuated by said magnet upon an excess of load in the secondary, a contact adjacent at side of said armature and adapted to be engaged by said contact-point upon the armature, a circuit including said motor, said connections and contact upon the armature and said adjacent contact-point, a second electrical connection and contact-point upon the opposite side of said armature from said first-mentioned connections, a second contact adjacent said second contact-point on the armature, a second circuit including the secondary of the auxiliary transformer, the motor, the second connection and contact-point of the armature and the contact adjacent thereto, said second armature contact-point being adapted to rest against said second contact when the armature is not actuated by the magnet, substantially as described.

6. In an apparatus of the character described, the combination of a primary circuit, a secondary circuit, a transformer connected to receive current from said primary circuit and to deliver the transformed current to said secondary circuit, a series of auxiliary transformers, means for automatically introducing said auxiliary transformers successively into the system in parallel with said first transformer and with each other said means consisting of a series of devices adapted to be successively actuated by a cumulative excess of load, substantially as described.

809,303. **MEANS FOR HOLDING SPOOLS AND SEWING-MACHINE BOBBINS.** FRANK A. HOLT, Holyoke, Mass. Filed Sept. 3 1904. Serial No. 223,315.



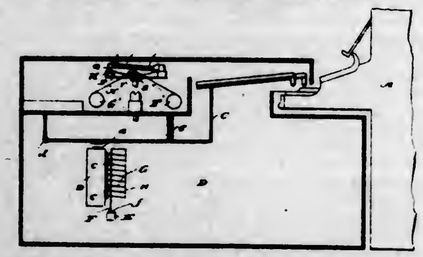
Claim.—A combined spool and bobbin holder comprising a base having a plurality of upstanding spool-receiving pins, and a perforated collar member adapted to receive and be mounted over the fixed spool-pin of a sewing-machine, whereby the latter constitutes one of the pins of the holder, said base being further provided with a bobbin-rack consisting of a lower fixed member and an upper vertically-adjustable member, said relatively fixed and adjustable members being provided with bearing elements receiving the axle-pin of a bobbin.

809,804. ROAD-CULVERT. WILLIAM IRMAN and FRANK B. MILLER, Isanti, Minn. Filed Dec. 15, 1904. Serial No. 237,601.

Claim.—1. A culvert comprising a base-section having inturned flanges at its side edges on its upper side, and side sections having outturned flanges at their lower sides to engage said inturned flanges of the base-section.

2. A culvert comprising a base-section and side sections, said base and side sections having coengaging devices to lock the said sections to the base-section and prevent the lower portions of the side sections from moving outwardly on the base-section, said side sections being further provided with means to secure their upper portions together and permit lateral movement of said upper portions.

809,805. ELECTRICAL PIANO-PLAYER. PARNELL B. KEBOE, Flemingsburg, Ky. Filed Apr. 27, 1905. Serial No. 257,621.



Claim.—1. In a player for pianos and other musical instruments, the combination of striking devices, electromagnets for depressing the striking devices; said electromagnets having terminals at intervals in the length of their helices and movable contact-pieces connected with said terminals, electromechanical means for moving the said contact-pieces, bars having portions designed to be engaged by said contact-pieces; said portions normally resting out of alinement with the contact-pieces, and electromechanical means for moving the bars to carry the said portions thereof into alinement with the contact-pieces.

2. In a player for pianos and other musical instruments, the combination of striking devices provided with armatures, electromagnets disposed below said armatures and having terminals at intervals in the length of their helices and movable contact-pieces, bars having portions designed to be engaged by said contact-pieces; said portions normally resting out of alinement with the contact-pieces, and electromechanical means for moving the bars to carry the said portions thereof into alinement with the contact-pieces.

3. In a player for pianos and other musical instruments, the combination of striking devices provided with armatures, electromagnets disposed below said armatures and having terminals at intervals in the length of their helices and vertically-movable contact-pieces connected with said terminals, vertically-movable bars having armatures, sleeves movable vertically on said bars and having loops receiving the contact-pieces, adjustable devices for supporting the sleeves on the vertical bars, electromagnets disposed below the armatures of the vertical bars, horizontally-movable bars having enlargements normally resting out of vertical alinement with the contact-pieces and also having armatures, and electromagnets for moving said bars horizontally.

4. In a player for pianos and other musical instruments, the combination of striking devices provided with armatures, electromagnets disposed below said armatures and having terminals at intervals in the length of their helices, a support, vertically-movable contact-pieces connected to said terminals and the support, vertically-movable bars having armatures, sleeves movable vertically on said bars and having loops receiving the contact-pieces, set-screws adjustable in bearings on the bars and supporting the sleeves, electromagnets disposed below the armatures of the vertical bars, horizontally-movable bars having enlargements normally resting out of vertical alinement with the contact-pieces and also having armatures, and electromagnets for moving said bars horizontally.

5. In a player for pianos and other musical instruments, the combination of a web, striking devices, electromagnets for depressing the striking devices; said electromagnets having terminals at intervals in the length of their helices and movable contact-pieces connected with said terminals, means controlled by the web for energizing said electromagnets, electromechanical means for moving the said contact-pieces, means controlled by the web for energizing said electromechanical means, bars having portions designed to be engaged by said contact-pieces; said portions normally resting out of alinement with the contact-pieces, electromechanical means for moving the bars to carry the said portions thereof into alinement with the contact-pieces, and means controlled by the web for energizing the latter electromechanical means.

6. In a player for pianos and other musical instruments, the combination of a tracker having a depression in its upper side, a web arranged to travel over said tracker and having perforations, electromagnets for depressing the striking devices; said electromagnets having terminals at intervals in the length of their helices and movable contact-pieces connected with said terminals, circuit-closers arranged above the tracker and having beveled projections adapted to fall through openings in the web and into the depression of the tracker; said circuit-closers being electrically connected with the said electromagnets and a source of electrical energy, electromechanical means for moving the said contact-pieces, circuit-closers arranged above the tracker and having beveled projections adapted to fall through openings in the web and into the depression of the tracker; said circuit-closers being electrically connected with the said electromechanical means and a source of electrical energy, bars having portions designed to be engaged by said contact-pieces; said portions normally resting out of alinement with the contact-pieces, electromechanical means for moving the bars to carry the said portions thereof into alinement with the contact-pieces, and circuit-closers arranged above the tracker and having beveled-projections adapted to fall through openings in the web and into the depression of the tracker; said circuit-closers being electrically connected with the latter electromechanical means and a source of electrical energy.

7. In a player for pianos and other musical instruments, the combination of striking devices, electromagnets for depressing the striking devices, and electromechanical means for carrying current from the helices of said electromagnets at different points in the length thereof.

8. In a player for pianos and other musical instruments, the combination of striking devices, a web, electromagnets controlled by the web and arranged to depress the striking devices, and electromechanical means controlled by the web and arranged to carry current from the helices of said electromagnets at different points in the length thereof.

9. In a player for pianos and other musical instruments, the combination of a vertically-movable tracker, a web movable over the tracker, means for normally supporting the tracker, electromechanical means controlled by the web for releasing the tracker and permitting the same to move downwardly at a predetermined time, striking devices, electromagnets controlled by the web and arranged to depress the striking devices, and electromechanical means controlled by the web and arranged to carry current from the helices of said electromagnets at different points in the length thereof.

10. In a player for pianos and other musical instruments, the combination of a vertically-movable tracker, a web movable over the tracker, means for normally supporting the tracker and electromechanical means, controlled by the web, for releasing the tracker and permitting the same to move downwardly at a predetermined time.

11. In a player for pianos and other musical instruments, the combination of a vertically-movable tracker having a notch, a web movable over said tracker, an armature-latch normally resting in the notch of the tracker, an electromagnet arranged adjacent to said armature-latch, and means controlled by the web for energizing the electromagnet at a predetermined time.

12. In a player for pianos and other musical instruments, the combination of a vertically-movable tracker having a notch, a web movable over the tracker, striking devices, electromagnets controlled by the web and arranged to depress the striking devices, electromechanical means controlled by the web and arranged to carry current from the helices of said electromagnets at different points in the length thereof, an armature-latch normally resting in the notch of the tracker, an electromagnet arranged adjacent to the armature-latch, and means controlled by the web for energizing the said magnet at a predetermined time.

13. In a player for pianos and other musical instruments, the combination of striking devices, a web, electromagnets controlled by the web and arranged to depress the striking devices, electromechanical means controlled by the web and arranged to carry current from the helices of said electromagnets at different points in the length thereof, a source of electrical energy, and means, intermediate the source of electrical energy and the electromagnets, and controlled by the web for making the volume of the current supplied to the electromagnets correspond with the number of electromagnets energized at one and the same time.

14. In a player for pianos and other musical instruments, the combination of a web, striking devices, electromagnets controlled by the web for depressing the said striking devices, a source of electrical energy, a receptacle containing conductive substance and connected with the source of electrical energy, a second receptacle containing conductive substance electrically connected with the electromagnets, a plurality of receptacles containing conductive substance and connected by resistances with the second-mentioned receptacle, armatures for connecting the first-mentioned receptacle and the plurality of receptacles, electromagnets controlling said armatures, and means controlled by the web for energizing said electromagnets.

15. In a player for pianos and other musical instruments, the combination of a web, a source of electrical energy, a receptacle containing conductive substance and electrically connected with the source of electrical energy, a second receptacle containing conductive substance, striking devices, electromagnets controlled by the web and connected with the second-mentioned receptacle for depressing the striking devices, a plurality of receptacles containing conductive substance connected by resistances with the second-mentioned receptacle, armatures for electrically connecting the first and second mentioned receptacles, magnets for moving said armatures, and means controlled by the web for energizing said magnets.

16. In a player for pianos and other musical instruments, the combination of a vertically-movable tracker, a web movable over the tracker, means for winding the web from one roller to another, the said rollers, a driving connection for the rollers, movable means controlled by the web for normally supporting the tracker and means controlled by the web for reversing the driving connection.

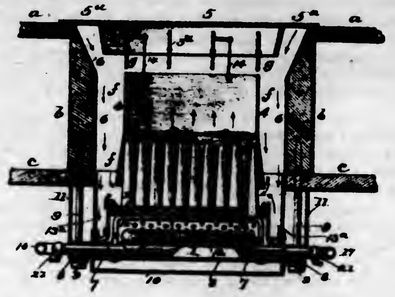
17. In a player for pianos and other musical instruments, the combination of a web, striking devices, electromagnets controlled by the web and arranged to actuate the striking devices, means controlled by the web and arranged to regulate the strength of the blows of the striking devices, and means controlled by the web for regulating the volume of current supplied to the electromagnets.

18. In a player for pianos and other musical instruments, the combination of a web, a vertically-movable tracker supporting the same, means for normally supporting the tracker, electromechanical means controlled by the web and arranged to release the tracker and permit the same to move downwardly at a predetermined time, striking devices, electromagnets controlled by the web and arranged to actuate the striking devices, means controlled by the web and arranged to regulate the strength of the blows of the striking devices, and means controlled by the web for regulating the volume of the current supplied to the electromagnets.

19. In a player for pianos and other musical instruments, the combination of a web, a vertically-movable tracker supporting the same, means for supporting the tracker, electromechanical means controlled by the web and arranged to release the tracker and to permit the same to move downwardly at a predetermined time, striking devices, electromagnets controlled by the web and arranged to actuate the striking devices, means controlled by the web and arranged to regulate the strength of the blows of the striking devices, means controlled by the web for regulating the volume of current supplied to the electromagnets, means controlled by the web for reversing the direction of movement of the web when the tracker moves downwardly, and means controlled by the web for breaking the circuits connected with the electromagnets for actuating the striking devices.

809,806. AIR-HEATING SYSTEM. FRANKLIN S. LARMON, Washington, D. C., assignor to Cosmos Construction Company, Washington, D. C., a Corporation of District of Columbia. Filed Mar. 27, 1903. Renewed June 7, 1905. Serial No. 264,167.

Claim.—1. In an air-heating system, the combination with a register, of a jacket which is open at top and bottom, and arranged beneath the register-box, the upper edge of which jacket is spaced down from the lower part of such register-box, thereby forming a passage *g*, through which the air can pass in either direction, substantially as shown and described.



2. In an air-heating system, the combination with a register, and a jacket spaced down from the register-box, of an inclosing jacket 6 which is spaced from its interior jacket, thereby forming an air-passage between the two which communicates at the top of the inner jacket with the air-passage therein, substantially as shown and described.

3. In an air-heating system, the combination with a register, of an air-conducting jacket spaced below it, a heater arranged below said jacket and spaced therefrom, and an inclosing jacket spaced from the first-named one, substantially as shown and described.

4. In an air-heating system, the combination with a register, of an air-conducting jacket 4 arranged below it and adapted for vertical adjustment, whereby it serves to regulate the passage of air between the register and jacket, substantially as shown and described.

5. In an air-heating system, the combination with a register, and an air-conducting jacket arranged below it and adapted for vertical adjustment, of an inclosing jacket 6, spaced from the inner jacket, substantially as shown and described.

6. In an air-heating system, the combination with a register, of an air-conducting jacket arranged below it and adapted for vertical adjustment, and means for adjusting it, substantially as shown and described.

7. In an air-heating system, the combination with a register, of an air-conducting jacket arranged below it and adapted for vertical adjustment, and connecting devices which suspend the jacket from the pivoted leaves of the said register, substantially as shown and described.

8. In an air-heating system, the combination with a register, a vertically-adjustable jacket 4 arranged below, and means for adjusting it, of an inclosing fixed jacket 6, spaced from jacket 4, substantially as shown and described.

9. In an air-heating system, the combination with a heater-plate, of a jacket arranged over said plate and adapted for vertical adjustment, whereby it may serve to control access of air to the plate, substantially as shown and described.

10. The combination with a heater-plate, and a vertically-adjustable jacket arranged directly over it, of an inclosing jacket 6, spaced from the first one to form an air-passage, and connected at its lower end with said plate, substantially as shown and described.

11. The combination with a heater-plate, and a vertically-adjustable jacket arranged directly over it, of an inclosing jacket 6, spaced from the first one to form an air-passage, and having a trough-like extension 13ª descending below said plate and returning to connect therewith, substantially as shown and described.

12. The combination with a heater-plate, and the fixed jacket 6, of the downward trough-like extension of the jacket, 13ª, which is arranged loosely within the lower portion of said jacket, and is removable vertically therefrom, substantially as shown and described.

13. In an air-heating system, the combination with a heater-plate, and a vertically-adjustable jacket arrange dover it, of a register arranged over said jacket and spaced therefrom, substantially as shown and described.

14. In an air-heating system, the combination with a heater-plate, and a vertically-adjustable jacket 4 over it, of a register spaced above, and an inclosing jacket 6 spaced from, said jacket 4, substantially as shown and described.

15. In an air-heating system, the combination with a heater-plate, of a jacket which is open at top and bottom and arranged above

the plate, and adapted for vertical adjustment, and means for adjusting it, substantially as shown and described.

16. In an air-heating system, the combination with a heater-plate, and a register having pivoted leaves, of a vertically-adjustable jacket arranged between the plate and register, and open at each end, and means connecting the jacket with the register-leaves, whereby the adjustment of the latter in opening and closing correspondingly adjusts the jacket higher or lower and thus regulates the admission of air to the heater-plate, substantially as shown and described.

17. In an air-heating system, the combination with a heater-plate and a register having pivoted leaves, of a vertically-adjustable jacket 4, and connecting devices which suspend the jacket from the leaves of the register, whereby simultaneous adjustment of register and jacket is secured, substantially as shown and described.

18. In an air-heating system, the combination with a heater-plate, burners arranged beneath the same, and a jacket which is open at each end and adapted for vertical adjustment, of means for opening and closing the burners, and adjusting the jacket, for simultaneously regulating supply of gas and air, substantially as shown and described.

19. In an air-heating system, the combination with a heater-plate, burners arranged beneath the same, a vertically-adjustable jacket which is open at each end and arranged above said plate, of a register, and means connecting the operative parts of the register with said jacket and the burners, whereby the register and stop-cocks are opened and closed and the jacket adjusted simultaneously, substantially as shown and described.

20. In an air-heating system, the combination with a heater-plate, and a register having pivoted leaves and an operative lever, of a vertically-adjustable jacket 4 and connecting devices which suspend the jacket from the register-leaves, and burners provided with stop-cocks whose operative levers are connected by link-and-lever mechanism with the operative lever of the register, whereby simultaneous adjustment of register, jacket and burners is secured, substantially as shown and described.

21. In an air-heating system, the combination, with a heater-plate, a vertically-adjustable jacket 4 over said plate, burners beneath the plate provided with stop-cocks 21 having levers, and a register-bar 27 having a pivoted operating-lever 28, of bars 23 having hooks which connect them detachably with the stop-cock levers, and means comprising pivoted levers 24, 24', 25 and 26, which serve to connect the said register-bar with the hook-bars 23, substantially as described.

22. In an air-heating system, the combination with a heater-plate, a burner beneath the same, a movable bar detachably connected with the stop-cock of said burner, and means for operating said bar, of a second burner arranged contiguous to the first so that one may light from the other, and a device attached to such second burner and adapted to engage with and lock the operative bar of the first-named one, the turning out of the flame of the second burner thereby preventing the opening of the first burner until the second one is relighted, substantially as shown and described.

23. In an air-heating system, the combination with a heater-plate, and a fixed bar, a series of burners arranged beneath the plate, detachable bars connecting the stop-cocks of said burners, and means for operating said bars, of another burner arranged contiguous to each of said series, and a movable bolt or bolts connected with the stop-cock lever of the last-named burner, the fixed and one or more movable bars being provided with notches which coincide when a movable notched bar is adjusted for closing the cocks, and thus form a socket adapted to receive the said bolt, substantially as shown and described.

24. In an air-heating system, the combination with a heater-plate, a fixed bar, a register provided with a pivoted lever, and detachable bars connecting the stop-cock levers of a series of burners, of another burner arranged adjacent to one or more of said series, and having a locking-bolt adapted to engage notches in the fixed and movable bars, and link-and-lever mechanism operatively connecting the movable bars with the register-lever, substantially as shown and described.

25. In an air-heating system, the combination with a register having an open-work side extension of its plate, of a jacket 4 arranged below whose upper edge is separated from the register-box, whereby an opening *g* is formed between them for the passage of air through the said side extension when the register is closed, substantially as shown and described.

26. The combination with a register having an open-work side extension, and a heater arranged below, of a jacket whose upper edge is separated from the register-box, whereby an opening between them is provided for passage of heated air when the register is closed, substantially as shown and described.

27. The combination with a register having an open-work side extension, a heater arranged below, and a jacket whose upper edge is separated from the register-box, of an inclosing jacket 6, substantially as shown and described.

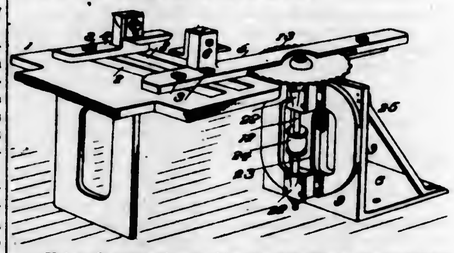
28. The combination with a register having an open-work side extension, a heater arranged below, and an inclosing jacket 6, of a jacket 4 arranged between the heater and the register, and whose upper and lower edges, respectively, are separated from the said register and the said heater, substantially as shown and described.

29. In an air-heating system, the combination with a horizontal heater-plate having a series of vertical cones, of a vertically-movable jacket inclosing the upper portion of the cones, but separated from the heater-plate proper, a register arranged above the jacket and provided with pivoted leaves which are operatively connected with the jacket, a fixed jacket arranged exterior to the register-box and separated from the movable jacket by a narrow space, and having a downward trough-like extension projecting below the heater-plate and opposite the burners, and a perforated casing arranged beneath the burners and serving to inclose the same, substantially as shown and described.

30 The combination with the heater-plate, burners and perforated casing, of jacket 4 adapted for vertical adjustment, substantially as shown and described.

31. In an air-heating system, the combination with the heater-plate provided with upwardly-projecting cones, of the jacket 4, made vertically adjustable, and its lower end adapted to inclose the cones more or less according to the adjustment, substantially as described.

809,307. RESAWING-MACHINE. LENORD A. LAWSON, McBee, S. C. Filed May 3, 1905. Serial No. 258,062.

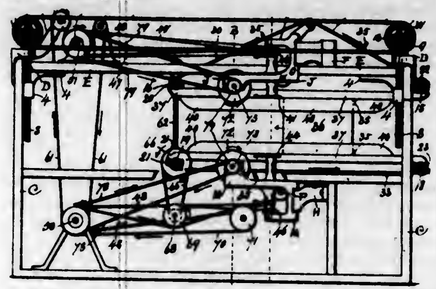


Claim.—In a resawing-machine, the combination of a supporting-base provided with a vertically-extending standard or plate provided at its lower end with a projection 21, and also provided with a plurality of elongated slots, a bar mounted at one side of said plate and provided at its lower end with an outwardly-projecting extension, an adjusting device or screw working through the projection 21 against the said extension whereby to move the said bar vertically, a mandrel-supporting frame supported at its lower end on the said extension and abutting against the outer face of the said bar and provided with upper and lower curved slots, fastenings or bolts accommodated in said slots and extending through said bar and through the slots in the plate, a pivoted bolt secured to said frame and passing through one of the slots in the plate, a bearing-plate 23 attached to the outer side of the mandrel-supporting frame and over the heads of the said bolts whereby the latter are retained in position as against longitudinal displacement, and a mandrel or shaft journaled in said bearing-plate and carrying a saw at one end, as for the purpose set forth.

809,308. MACHINE FOR TRIMMING THE CORNERS OF BOXES. JAMES T. LECHMERE, Hamilton, Canada. Filed July 24, 1905. Serial No. 270,269.

Claim.—1. In a machine for trimming the corners of boxes, a rigid frame, an upper frame adapted to vertically slide in the rigid frame, an upper transverse guide secured to the slidable frame and a similar guide secured to the rigid frame and below the upper guide, upper and lower bearings secured to said guides, and in vertical line, similar upper and lower bearings adapted to slide on the upper and lower guides, and in vertical line, means on the rigid frame and on the adjustable frame to vertically adjust the adjustable frame, means on the rigid frame and on the adjustable frame to horizontally adjust said adjustable bearings, and box-corner-trimming means.

2. In a machine for trimming the corners of boxes, a rigid frame, corner-posts in the frame, bearings secured to the upper parts of the posts, vertical grooves on the inner sides of the posts, an adjustable frame, guides secured to the frame-tongues on the guides adapted to slide in the grooves, transverse shafts journaled in bearings of the rigid frame, bevel-wheels secured on the outer ends of the shafts, sprocket-wheels on the shafts, a chain connecting the sprockets, vertical screws through said bearings and guides, bevel-wheels on the screws meshing in the bevel-wheels on the shafts, a crank-handle on one said shaft to adjust the adjustable frame, and box-corner-trimming means.



3. In a machine for trimming the corners of boxes, a rigid frame, an adjustable frame in said rigid frame, a transverse guide secured to the adjustable frame, bearing secured to the guide, a similar bearing adapted to slide on the guide, a vertical shaft adapted to revolve in the stationary bearing, a similar shaft adapted to revolve in the slidable bearing, a pulley on each shaft, a horizontal saw secured on the lower end of each shaft, means on the adjustable frame to revolve said pulleys, transverse shafts extending through said bearings, and adapted to revolve therein, a pulley on each shaft, vertical saws a part on each said shaft, and means for revolving the shafts.

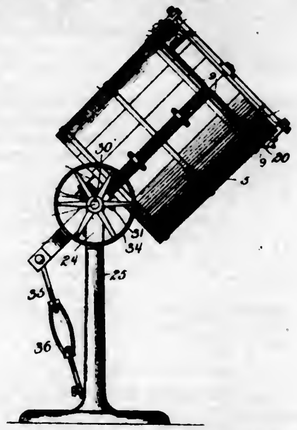
4. In a machine for trimming the corners of boxes, a rigid frame, an upper frame adapted for vertical adjustment therein, transverse guides secured to each said frame, and in vertical line, stationary bearings secured to said guides and in vertical line, adjustable bearings on the guides and opposite to the stationary bearings, means connected to the rigid frame and to the adjustable bearings for adjusting the adjustable bearings, a vertical shaft in each said bearing, a pulley on each shaft, a horizontal saw on the end of each shaft and vertically opposite to each other, an upper and a lower horizontal shaft extending through the respective upper and lower bearings, a pulley on each of said horizontal shafts and a vertical saw secured on each of said horizontal shafts.

5. In a machine for trimming the corners of boxes, a rigid frame, a frame adapted for vertical adjustment in the rigid frame, upper and lower transverse guides secured to said frames, bearings rigid on said guides, similar bearings adapted to slide on the guides, opposite horizontal saws and opposite vertical saws adapted to revolve and supported by said bearings, upper and lower chain-supports, sprockets supported on the adjustable frame, lower and vertically-opposite sprockets supported by the rigid frame, feed-chains connecting the upper sprockets and feed-chains connecting the lower sprockets, dogs on the feed-chains, supports on the adjustable frame for the feed-chains and supports on the rigid frame for the feed-chains and boxes.

6. In a machine for trimming the corners of boxes, a rigid frame, an adjustable frame to vertically slide therein, stationary bearings supported by said frames, adjustable bearings supported by said frames, horizontal chain-supports secured on said bearings, transverse shafts supported by said frames and apart from each other and in vertical line, sprockets on said shafts, horizontal chains connecting the upper sprockets, and horizontal chains connecting the lower sprockets, and in said horizontal supports, dogs on the chains, side box-guides on the chain-supports, means for adjusting the frame, means for adjusting the bearings, means for revolving the sprockets, and box-corner-trimming means.

7. In a machine for trimming the corners of boxes, a rigid frame, an adjustable frame adapted to vertical adjustment therein, means to adjust the frame, a bearing secured to one side of the adjustable frame and a similar bearing on the adjustable frame and adapted to horizontal adjustment, a vertical shaft adapted to revolve in each bearing, a pulley on each shaft, a horizontal saw on the lower end of each shaft, means on the adjustable frame for revolving the shafts, a transverse shaft extending through the bearings, a pulley on each shaft, a vertical saw secured to one end part of the horizontal shaft, a similar saw on the opposite end part of the shaft and adapted to slide thereon, and means for adjusting the saw.

809,309. ELECTROPLATING APPARATUS. ARTHUR W. L'HOMMEDIEU, Chicago, Ill., assignor to Charles F. L'Hommedieu, Chicago, Ill. Filed Apr. 22, 1905. Serial No. 256,230.



Claim.—1. In a device of the character described, the combination of a tub adapted to contain a plating solution, and arranged to be rotated upon an axis laterally inclined from a vertical plane, one or more anodes secured near the inner surface of the tub, one or more resident cathodes near the axis of the tub and a perforate receptacle of non-conducting material, adapted to contain the material to be plated interyening between the said electrodes.

2. In a device of the character described, the combination of a plating-tub adapted to contain a plating solution and arranged to be rotated upon an upwardly-extending axis, anodes arranged around the inside surface of said tub, a resident cathode arranged near the axis of said tub, a non-conducting support for the material to be plated, electric connections for said anode and resident cathode and a means for rotating the tub.

3. In a device of the character described, the combination of a plating-tub adapted to contain a plating solution and arranged to be rotated upon an upwardly-extending axis, anodes arranged around the inside surface of said tub, a resident cathode arranged near the axis of said tub, a non-conducting, perforate cylinder, for supporting the material to be plated, arranged intermediate the said anodes and resident cathode, electric connections for said anodes and resident cathode and a means for rotating the tub.

4. In a device of the character described, the combination of an imperforate cylinder closed at its base end, arranged to be rotated upon an upwardly-extending axis, a removable perforate cylinder of non-conducting material closed at its base end, arranged within said first cylinder, an anode arranged between said cylinders, a resident cathode within the interior cylinder, electric connections and a means for rotating said cylinders.

5. In a device of the character described, the combination with a plating-tub provided with an anode, a metallic pan constituting a part of the cathode arranged near the bottom of the tub to support the material to be plated, a perforate non-conducting screen between said anode and resident cathode, a means for adjusting the inclination of the tub, electric connections, and a means for rotating said tub.

809,310. COPY-HOLDER. ARTHUR D. LONG, Fairfield, Iowa, assignor of one-half to George Dietz, Fairfield, Iowa. Filed May 6, 1905. Serial No. 259,169.

Claim.—1. In combination, a base, a support mounted in said base, a sleeve mounted on the support, said sleeve having an end bifurcated, a segmental bracket mounted in the bifurcation of the sleeve, said bracket having its curved edge notched, a table secured

to the base of the bracket a ball within the sleeve adapted to fit within one of the notches of the segment and to contact with the wall of the sleeve, a plug within the sleeve, and a spring interposed between the plug and ball to force and hold said ball within a notch of the segment.

2. In combination with a mounted support, a table carried thereby, said table having grooves in its opposite sides, a cross-wire carried by the table, and a U-shaped clip having its ends secured to the opposite sides of the table, the free portions of the clip being contracted and fitted within the grooves of the table.

3. In combination, a supported table, a book-engaging means extending across the table and secured to the sides thereof, and a spring-clip secured to the sides of the table and extending across the table above the engaging means, the engaging means being arranged with relation to the clip to prevent the spreading thereof.

4. In combination, a supported table, a wire extending across the table, the ends of the wire being secured to the sides of the table, and a spring-clip secured to the sides of the table and extending across the table, said clip passing beneath the wire and having its movement limited by said wire.

809,311. **FIREPROOF WIRE.** ARÂNDA M. LOUGHE, Boston, Mass. Filed Nov. 5, 1903. Serial No. 179,989.

Claim.—1. As an article of manufacture, a permanently-flexible armored electric conductor of indeterminate length having an external size adapted to the usual wiring requirements of office-buildings, and having its component parts held integrally and permanently together by adhesion, said parts including a wire, a fireproof jacket for the wire, a waterproof covering for said jacket, and a tightly-woven-wire covering provided internally and externally with a waterproof and fireproof covering of insulation.

2. As an article of manufacture, a permanently-flexible armored electric conductor of indeterminate length having an external size adapted to the usual requirements of office-buildings, and having its component parts held integrally and permanently together by adhesion, said parts including a wire, an asbestos jacket for the wire rendered moisture-proof by an enveloping coating of cement, inclosed by a tightly-woven jacket of wire embedded on both sides in waterproof and fireproof insulation.

809,312. **PROCESS OF MAKING FIREPROOF CONDUCTORS.** ARÂNDA M. LOUGHE, Boston, Mass. Filed May 23, 1904. Serial No. 209,191.

Claim.—1. The herein-described process, consisting of coating a conductor-wire with a cover of approximately pure rubber, applying to said rubber coating a plurality of vulcanizable coatings containing insulating and fireproofing ingredients, with increasing proportions of the latter in successive coatings, applying a woven-wire jacket tightly thereto, applying a highly-heated, thin, vulcanizable, fireproof and electrolysis-proof insulating compound to said wire jacket, maintaining said jacket and the adjacent contained portions highly heated during said application, repeating said application of said thin compound a plurality of times until said compound has permeated the meshes of the jacket and become incorporated therewith entirely about the individual strands and on both sides of the jacket, said jacket being permitted to cool appreciably between successive applications of said compound, then applying a heavy coating of vulcanizable, fireproofing compound, and finally vulcanizing the whole together.

2. The herein-described process, consisting in providing a conductor-wire with vulcanizable insulation and then applying a metal jacket thereto, applying to said jacket a fireproof and electrolysis-proof insulating vulcanizable, plastic compound, heating said compound and metal jacket during said application sufficiently to incorporate the compound in the jacket, and then permitting the same to cool and repeating said treatment, heating and cooling, until the metal jacket is covered with a thick coating and finally vulcanizing the whole together.

3. The herein-described process, consisting in applying to a conductor-wire successive dippings of insulating and fireproofing compound, the first dippings consisting exclusively or principally of insulating material and the fireproof ingredients predominating in the outer dippings, said compound containing material for rendering the product permanently flexible, and also containing a vulcanizing agent, next applying a fibrous covering permeated throughout with fireproof material, applying thereto a coating of vulcanizable fireproof and insulating compound, weaving a wire jacket tightly thereon, treating said jacket under heat to a hot coating of electrolysis-proof vulcanizable compound, as described, and finally treating the whole to a vulcanizing process.

4. The herein-described process, consisting in providing a conductor-wire with a vulcanizable and permanently-flexible covering of insulation containing fireproofing ingredients, embedding therein, while still in a plastic state, a flexible covering of closely-woven wire, repeatedly dipping the aforesaid in a thin plastic vulcanizable compound of insulating, permanently-flexible, fireproof materials, maintaining both the wire covering and thin compound highly heated during said dippings, and applying to the exterior a thick, permanently-flexible coating of vulcanizable compound containing insulating, fireproofing and waterproofing ingredients, the latter two predominating, and finally vulcanizing the whole sufficiently to unite all of said parts together into a flexible, unitary article.

809,313. **PROTECTED CONDUCTOR.** ARÂNDA M. LOUGHE, Boston, Mass. Filed May 23, 1904. Serial No. 209,192.

Claim.—1. As an article of manufacture, a protected conductor, comprising an inner conductor-wire, an enveloping compound of insulating and fireproof ingredients having an increasing quantity of the latter on its outer side, a covering of fireproof fabric surrounding said compound and permeated on both sides with fireproof materials, a woven-wire jacket tightly embedded in the fireproof materials on the outer side of said fabric covering, and a coating of fireproof compound inclosing said wire jacket, the whole containing vulcanizing ingredients and being vulcanized together as a one-piece article.

2. As an article of manufacture, an inner conductor-wire, an enveloping vulcanizable compound containing a maximum quantity of insulating ingredients adjacent the wire, and an increasing quantity of fireproofing ingredients toward its outer side, a coarse-mesh woven-wire jacket filled and permeated on both sides with a vulcanizable compound containing fireproofing and insulating ingredients, and a superimposed fine-mesh woven-wire jacket, permeated on both sides with a vulcanizable compound containing fireproofing, insulating and waterproofing ingredients, the whole being vulcanized together as a one-piece article.

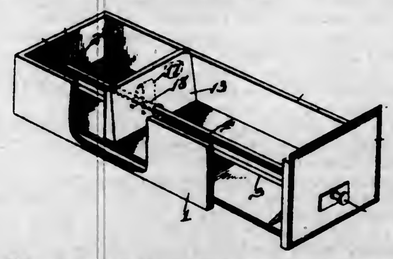
3. As an article of manufacture, an inner conductor-wire, an enveloping vulcanizable compound of insulating and fireproofing ingredients, a tightly-woven wire jacket, having a vulcanizable, fireproofing and insulating compound incorporated therewith on both sides and permeating the meshes thereof, and a thick external coating, having a large number of layers of vulcanizable, permanently-flexible compound, containing ingredients as described for rendering the same moisture-proof, electrolysis-proof and fireproof, and the whole being vulcanized together as a one-piece article.

4. As an article of manufacture, a cable, containing a plurality of individual conductor-wires, each embedded in a compound containing substantially pure insulating material adjacent the wire and an increasing proportion of vulcanizable and fireproofing ingredients externally thereof, all of said wires thus covered being together inclosed in a similar enveloping compound, and a plurality of woven-wire jackets separated from each other, and each embedded in and permeated by, a vulcanizable compound containing insulating and fireproofing ingredients, the inner jacket having coarse-mesh and fine wire and the outer jacket having coarse wire tightly woven, and an outside covering of thick, vulcanizable, fireproof, waterproof and insulating compound, the whole being vulcanized together, and permanently flexible.

5. As an article of manufacture, a cable, containing a plurality of individual conductor-wires permanently insulated from each other, and an enveloping compound of vulcanizable, insulating, fireproofing ingredients, a coarse-mesh fine-wire jacket, tightly inclosing said compound, a thin coating of similar compound incorporated therewith as stated, a thick coating of similar compound, containing an increased quantity of fireproofing ingredients, inclosing the same, a close-woven fine-wire jacket thereon, a further covering of similar compound similarly arranged, a close-woven coarse-wire jacket, and a thick coating of similar compound enveloping the whole, all being vulcanized together as a one-piece article.

6. As an article of manufacture, a protected conductor, comprising an inner conductor-wire, an enveloping compound of insulating and fireproofing ingredients, and a plurality of woven-wire jackets separated from each other by vulcanizable, fireproof insulating compound, and also permeated with said compound, the whole being vulcanized together and permanently flexible, the wire of the outer jacket having great tensile strength and hardness, and the wire of the inner jacket being lighter and more flexible.

809,314. **CARD-INDEX DRAWER.** WILLIAM LUBLEY, Chicago, Ill. Filed Dec. 4, 1903. Serial No. 133,230.



Claim.—1. In a card-index drawer the combination of the drawer, a card-holding rod journaled therein and having an eccentric portion adapted to stand out of line with the entrance to the slot of the card for holding the card in place, and a deflectable member normally engaging said eccentric portion for holding the rod against rotation, and adapted to be deflected out of engagement with said eccentric portion for permitting the rod to rotate, substantially as set forth.

2. In a card-index drawer the combination of the drawer, a flattened rod journaled therein and having a notched or narrowed portion and a deflectable plate engaging said rod adjacent to said notched or narrowed portion for holding the rod against rotation when in one position and permitting of its rotation when deflected opposite the notched or narrowed portion, substantially as set forth.

3. In a card-index drawer the combination of the drawer, a rotatable flattened rod journaled therein and having a narrowed or notched portion and a deflectable plate having a notch in which said rod engages, one side of the notch in said plate extending but partially across said rod, substantially as set forth.

4. In a card-index drawer the combination of the drawer, a rotatable flattened rod journaled therein and having a notched or narrowed portion and a deflectable holder for said rod embracing the edge thereof at a point adjacent to said notched or narrowed portion, substantially as set forth.

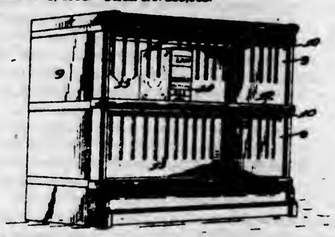
5. In a card-index drawer the combination of the drawer, a rotatable flattened rod journaled therein and having a notched or narrowed portion and a deflectable plate having a notch in which said rod engages, one side of said notch being of less length than the width of said rod and having the lip 12, substantially as set forth.

6. In a card-index drawer, the combination of a drawer, a card-holding rod secured in the bottom thereof, a follower-block located across said drawer and a spring-tongue secured rigidly at one end directly to said block and having its other end provided with an aperture in which said rod fits, said tongue being arranged normally at an angle to the face of the block and at an obtuse angle to the rod and flexible toward said face of the block.

7. In a card-index drawer the combination of the drawer, a flattened rod journaled in said drawer longitudinally thereof, a follower in said drawer and a V-shaped spring-plate secured to said follower and having registering apertures for the passage of said rod, substantially as set forth.

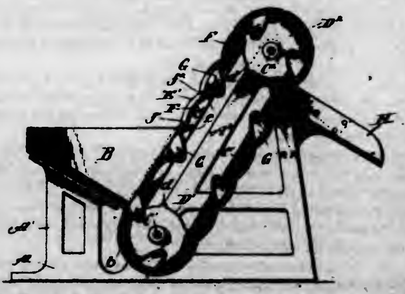
8. In a card-index drawer, the combination of a drawer, a card-holding rod secured therein, a follower located across the drawer and a spring-tongue secured at one end to the follower and projecting normally at an angle to the face of the follower and having an aperture through which the said rod passes and gripping and binding said rod, the spring being compressible toward said face of the follower for releasing the rod.

809,315. **BOOK-SUPPORT.** JAMES MACCALLUM, St. Louis, Mo. Filed Dec. 1, 1904. Serial No. 235,012.



Claim.—The combination with a bookcase, of attaching-plates secured to the inner faces of the end walls of said case immediately beneath the front of the book-shelf, a rod having its ends mounted in the attaching-plates, a series of tubular sleeves rotatably arranged on the rod, the series of sleeves extending from one end of the rod to the other, and a supporting-finger rigidly fixed to and depending from each sleeve, substantially as specified.

809,316. **CONVEYER.** JOHN W. MACKIN, Chicago, Ill., assignor to Chester T. Drake, Chicago, Ill. Filed Jan. 24, 1903. Serial No. 140,343.



Claim.—1. The combination with a supporting-frame, of guide-wheels journaled at the top and bottom of said frame and located out of vertical alinement, an endless conveyer passing around said wheels and comprising buckets and intermediate plates having overlapping adjacent edges, the tops of the buckets being flush with the surface of intermediate plates, a supply-hopper the lower edge of which terminates adjacent to said conveyer and lies below the axis of the lower guide-wheels, and a chute supported by said frame and located beneath the upper guide-wheel.

2. The combination with an endless conveyer comprising a series of buckets, and plates pivotally connected at their ends to the

adjoining ends of the buckets, of guide-wheels within the opposite ends of said conveyer around which it travels, the tops of the adjacent buckets and plates being flush and having overlapping edges whereby a smooth surface between the buckets is formed when the conveyer follows a curved path of movement around the guide-wheels.

3. An endless conveyer comprising a series of buckets and plates pivotally connected at their ends to the adjoining ends of the buckets, said buckets and plates being interchangeable whereby the capacity of the conveyer may be varied.

4. In a conveyer, the combination with a chain, of buckets supported by said chain, and plates also carried by the chain and interposed between the buckets thereby forming a smooth surface to guide the material falling upon the conveyer into the buckets, said buckets and plates being interchangeable whereby the capacity of the conveyer may be varied.

5. In a conveyer, the combination with an endless chain, of buckets supported by said chain, plates also supported by said chain between the buckets, guide-wheels within the opposite ends of said conveyer around which it travels, the tops of the buckets being flush with the surface of the plates and said buckets and plates having overlapping adjacent edges whereby a smooth surface is formed to guide the material falling upon the conveyer into the buckets and a continuous smooth surface between the buckets is formed when the conveyer passes around said guide-wheels.

6. In a device of the character described, the combination with a hopper, of a conveyer comprising an endless chain, buckets supported by said chain, plates also supported by the chain between the buckets, a guide around which said chain passes located adjacent to the delivery end of said hopper, and an apron extending downwardly from the bottom of said hopper partially around said guide and occupying a position adjacent to the path of movement of the conveyer.

7. In an endless conveyer, the combination with a chain comprising pairs of vertical links, of buckets secured between pairs of links and located below the outer edges thereof, plates also secured between pairs of links and located below the outer edges thereof, the adjacent buckets and plates having overlapping edges.

8. In an endless conveyor, the combination with a chain comprising pairs of vertical links, of buckets secured between pairs of links and located below the outer edges of the links, plates also secured between pairs of links below the outer edges thereof, whereby the outer portions of the links constitute flanges to retain the material upon the conveyer.

9. In an endless conveyer, the combination with a chain comprising pairs of vertical links, rods extending through the ends of the adjoining pairs of links, buckets secured between pairs of links and located below the outer edges thereof, plates also secured between pairs of links and located below the outer edges thereof, and guide-wheels around which the chain passes having grooves for receiving said rods.

10. In a conveyer, an element comprising a pair of vertical links, ribs projecting laterally from the opposing surfaces of the links, and a plate located between the links and secured to the ribs thereon.

11. In a conveyer, an element comprising a pair of vertical links, ribs projecting laterally from the opposing surfaces of the links, and a bucket located between the links and having flanges secured to the ribs thereon.

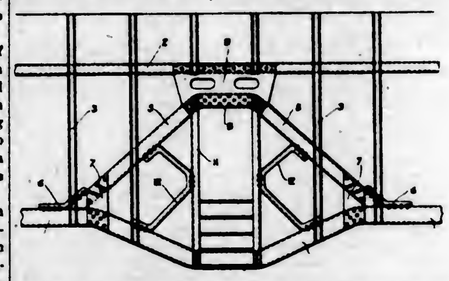
12. In a conveyer, an element comprising a pair of vertical links, ribs projecting laterally from the opposing surfaces of the links, a bucket located between the links and secured to the ribs thereon, said bucket comprising a plate having a hole therethrough, and the bucket proper secured beneath said plate and registering at its top with the hole therethrough.

13. In an endless conveyer, the combination with a chain comprising vertical links the inner edges of which are concave, of buckets carried by said chain, guide-wheels around which the chain passes, and flanges projecting from said guide-wheels adapted to be engaged by and support the chain throughout the path of movement of the conveyer around the guide-wheels the peripheries of the guide-wheels conforming in curvature to the concavity of the inner edges of the links.

14. In an endless conveyer, the combination with a chain comprising pairs of vertical links, rods extending through the ends of the adjoining pairs of links, buckets secured between pairs of links, plates also secured between pairs of links, guide-wheels around which the chain passes having grooves for receiving said rods, and circular flanges on said guide-wheels, said flanges projecting into the path of movement of and supporting the links through engagement with the lower edges thereof.

15. The combination with an endless conveyer comprising a series of pivotally-connected longitudinally-curved buckets and plates, of guide-wheels around which the conveyer travels the peripheries of which conform to the curvature of the buckets and plates, the adjacent buckets and plates having overlapping edges whereby a smooth surface between the buckets is formed when the conveyer follows a curved path of movement around the guide-wheels.

809,317. CAR-FRAME. WILLIAM R. MCKEEN, JR., Omaha, Nebr. Filed May 29, 1905. Serial No. 262,860.



Claim.—1. In a car-frame, in combination, a longitudinal sill provided with a portion depressed below the main portion thereof and a raised portion bridging said depressed portion, and cross members connecting said raised and depressed portions.

2. In a car-frame, in combination, a sill comprising a portion depressed below the main portion and a portion bridging said depressed portion, and a side plate rigidly connected with said bridging portion of said sill.

3. In a car-frame, in combination, a sill comprising a portion depressed below the main portion thereof and a raised portion bridging said depressed portion, a side plate, studs connecting said sill and said side plate, and means rigidly connecting said raised portion of said sill with said side plate.

4. In a car-frame, in combination, a sill split longitudinally throughout a portion of its length into an upper and a lower portion, and a door-frame secured between said portions.

5. In a car-frame, in combination, a sill split longitudinally throughout a portion of its length into an upper and a lower portion, a pair of spaced upright members stretched between and connected with said upper and lower portions, and a brace secured to each of said members and having its upper and lower ends connected respectively with said upper and lower portions of said sill.

6. In a car-frame, in combination, an upper member, a lower member, a pair of cross members stretched between said upper and lower members, and braces having their central portions secured to said cross members and having their upper and lower extremities reversely inclined and secured respectively to said upper and lower members.

7. In a car-frame, in combination, a sill having a portion depressed below the main portion thereof and a raised portion bridging said depressed portion, a side plate rigidly connected with said raised portion, spaced cross members stretched between and connected with said raised and depressed portions, and a brace secured to each of said cross members, each of said braces having its upper and lower ends respectively secured to said raised and depressed portions of said sill.

8. In a car-frame, in combination, a sill having a portion depressed below the main portion thereof and a raised portion bridging said depressed portion, a side plate rigidly connected with said raised portion, spaced cross members stretched between and connected with said raised and depressed portions, a brace secured to each of said cross members, each of said braces having its upper and lower ends respectively secured to said raised and depressed portions, and stops extending within the car-frame from said depressed portion.

9. In a car-frame, in combination, a sill split longitudinally throughout a portion of its length into an upper and a lower portion, said lower portion being depressed below the main portion of said sill, a pair of spaced cross members stretched between and connected with said upper and lower portions and forming a door-frame, a side plate rigidly connected with said upper portion, and stops extending inwardly from said door-frame.

10. In a car-frame, in combination, a sill comprising a portion depressed below the main portion thereof and a raised portion bridging said depressed portion, a side plate, studs connecting said side plate and said sill, a pair of spaced cross members stretched between and connecting said raised and depressed portions of said sill and forming a door-frame, stops leading inwardly from said door-frame, a brace connected with each of said cross members, each of said braces having its upper and lower extremities connected respectively with said raised and dropped portions of said sill, and means rigidly connecting said raised portion with said side plate.

11. In a car-frame, in combination, a sill comprising a portion depressed below the main portion thereof and a raised portion bridging said depressed portion, said raised portion forming with said depressed portion substantially a rhomb, a side plate rigidly connected with said raised portion, and cross members stretched between the central parts of said raised and depressed portions.

12. In a car-frame, in combination, a sill comprising a portion depressed below the main portion thereof and a raised portion bridging said depressed portion, said raised portion forming with said depressed portion substantially a rhomb, a side plate rigidly connected with said raised portion, cross members stretched between the central parts of said raised and depressed portions, and inclined braces connecting each of said cross members with said raised and said depressed portions.

13. In a car-frame, the combination with an upper member, of a lower member divided intermediate its length and having one portion of such division extending upwardly toward said upper member, and the other portion of such division extending downwardly, and a frame arranged between the portions of the divided lower member.

14. In a car-frame, the combination of a sill divided intermediate its length, one portion of such division being dropped below the horizontal plane of the main portion of the sill, and the other portion of such division extending upwardly above the horizontal plane of the main portion of the sill, and a frame interposed between the portions of such division.

15. In a car-frame, the combination of a sill divided intermediate its length, and having the members of such division shaped to constitute substantially a rhomb, and a frame interposed in such division.

16. The combination of a sill divided intermediate its length, the members of such division being spread apart, a door-frame interposed between said members, and braces connecting said door-frame with the sides of said members.

17. In a car-frame, in combination, an upper side plate a sill having a portion thereof raised above the level of the main portion thereof, and means connecting said raised portion with said side plate.

18. In a car-frame, in combination, an upper side plate, a sill having a portion raised above the main portion thereof and rigidly connected with said upper side plate and means connecting the portions of said sill adjacent said raised portion, said last-mentioned means being positioned beneath said raised portion.

19. In a car-frame, a sill split longitudinally into an upper and a lower portion, said upper portion being raised above the main portion of said sill and rigidly connected with the upper portion of the frame.

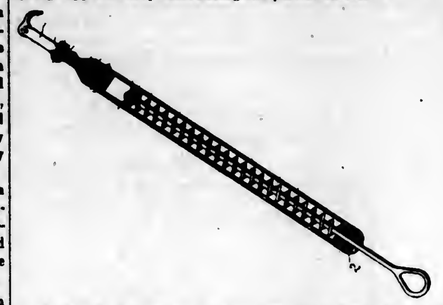
20. In a car-frame, in combination, an integral sill split longitudinally throughout a portion of its length into an upper and a lower portion, and a door-frame secured between said portions.

21. In a car-frame, in combination, an upper side plate, a sill having the central portion thereof raised above the level of the main portion thereof, and means connecting said raised portion with said side plate.

22. In a car-frame, an integral sill split longitudinally into an upper and a lower portion, said upper portion being raised above the main portion of said sill and rigidly connected with the upper portion of the frame.

809,318. DRAFT APPLIANCE. ANGUS MCNEIL, North Sydney, Canada. Filed Feb. 9, 1905. Serial No. 244,977.

Claim.—1. In a device of the character described, a tube, shouldered plugs therein at each end, one of said plugs being permanently connected to said tube and having a longitudinally-projected opening therein, a draft-rod projected through said opening, a loop or eyelet on the end of said rod, a spring upon said rod extending longitudinally of said tube, a disk upon said rod beyond said spring, a securing nut and pin upon said rod and beyond said disk, a pivotally-supported engaging hook connected with one of said plugs, and a spring-supported loop surrounding one portion thereof.



2. In a draft appliance, a tube, a plug secured therein at each end, said plugs being provided with shoulders abutting against the ends of said tube, in combination with a draft-bar projected through one of said plugs and extending longitudinally within said tube, a spring upon said draft-bar, a disk on said bar beyond said spring, means for securing said disk in position, an integral loop on said draft-bar, an engaging means extending longitudinally from and pivoted to the plug at the end of the device opposite said loop, and means for locking said engaging means in position.

3. In a device of the character described, a tube or cylinder provided with openings for admitting a lubricant therein, a plug brazed in one end of said tube, said plug being perforated longitudinally of said tube, a slidable draft-rod with a loop or eyelet thereon projecting through said plug and longitudinally within said tube, a disk at the inner end of said draft-rod, a spring on said rod between said disk and said plug, in combination with a plug at the opposite end of said tube, a rockable hook mounted on said plug, and a loop adapted to lock said hook in position.

4. In a device of the character described, a tube, plugs therein, one of which is perforated longitudinally of said tube, a longitudinally-slidable draft-rod, a spring thereon, means for holding said spring upon said rod, an integral loop on said rod, a pivotally-supported draft-hook connected with the opposite end of the device, and a rockable loop adapted to lock said hook.

5. In a device of the character described, a tube, a plug in one end with an opening therethrough, a slidable draft-bar extending through said opening into said tube, a spring thereon, a disk connected with the opposite end of said draft-rod, a removable plug in the end of said tube in proximity to said disk, a pivoted hook on said removable plug, and a yielding engaging member adapted to retain said hook in a locked position.

809,319. RESERVOIR-PEN. PAUL ORTWALL, Paderborn, Germany. Filed Oct. 21, 1904. Serial No. 229,743.

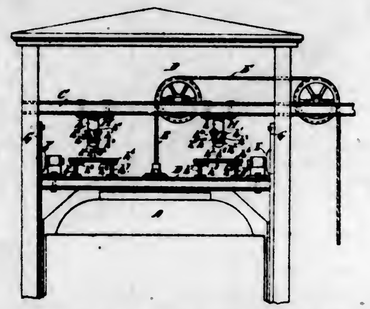
Claim.—In a writing-pen, a concavo-convex pen-body, a piece integrally connected with said body at one side and bent beneath the concave surface thereof, said piece having a projection at its free side, adapted for attachment to the pen-body and having a plurality of projections at its ends bent upwardly toward the pen-body, and a cake of solid ink, held between said piece and pen-body.

809,320. SAFETY DEVICE FOR ELEVATORS. FRED S. PAYNE, Boston, Mass. Filed Apr. 20, 1905. Serial No. 256,513.

Claim.—1. A safety device comprising a tongue-piece, a latch normally open, movably attached thereto, and a plate having an aperture, said tongue-piece and said plate being attached, one to the elevator-car, the other to some support outside the car and both said tongue-piece and said plate being so arranged as to interlock whenever the elevator-car ascends beyond a given point within the elevator-shaft.

2. A safety device comprising a tongue-piece having a shank with latches normally open, movably attached to said shank, said tongue-piece being rigidly attached to some support above the elevator-car and a plate having an aperture, said plate being rigidly at-

tached to the elevator-car; said tongue-piece and said plate being so arranged as to interlock whenever the elevator-car passes a given point.



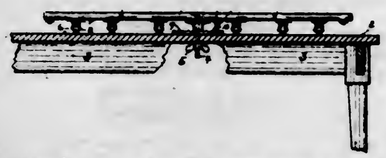
3. A safety device for elevators consisting of the combination of two interlocking members, one member being a tongue-piece with latches normally open, movably attached within a recess to said tongue-piece, the other member being a plate with an aperture adapted to allow the passage of said tongue-piece through said plate.

4. A safety device consisting in the combination of a tongue-piece with a latch normally open, movably attached thereto, a plate with an aperture adapted to allow said latch to pass through said plate, and means for causing said latch to resume its normal position after passing through said plate.

5. A safety device consisting in the combination of a tongue-piece with a latch normally open, movably attached thereto, a plate with an aperture adapted to allow said latch to pass through said plate, means for causing said latch to resume its normal position after passing through said plate, and stops on said plate to engage said latch.

6. The combination of a tongue-piece with a shank, having a recess, latches normally open, movably attached to said shank, a plate with an aperture adapted to permit the passage of said tongue-piece through said plate, means for causing said latches to close while passing through said plate, other means for causing said latches to open after passing through said plate, and stops on said plate to engage said latches.

809,321. SASH-SUPPORTING PLATFORM FOR GLAZIERS. FREDERICK J. PETERS, Milwaukee, Wis. Filed July 3, 1905. Serial No. 268,077.

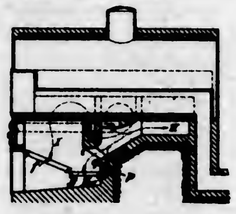


Claim.—In a glazier's table, the combination of a stationary table-top; a revoluble platform; means for connecting said revoluble platform at its center with said supporting-table top; a plurality of rollers connected with said revoluble platform and adapted to support the same from said table-top; an annular ratchet connected with the upper surface of said stationary table-top; a pawl pivotally connected with said platform, said pawl being adapted to move freely over said ratchet as the platform is moved in one direction and to engage said ratchet and lock said platform so as to resist the lateral pressure applied to said platform in the opposite direction, all substantially as and for the purpose specified.

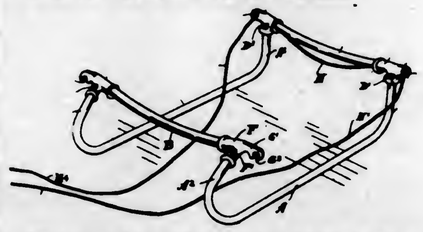
809,322. APPARATUS FOR THE COMPLETE COMBUSTION OF SOLID FUEL. ADAM PETERS, Frankfort-on-the-Main, Germany. Filed Mar. 17, 1904. Serial No. 198,681.

Claim.—1. In a furnace in combination, a grate, a main flue in the rear of said grate, combustion-spaces beside said main flue, air-inlets for said combustion-spaces, and air-inlets behind said grate into said main flue, said combustion-spaces having apertures communicating with said main flue, substantially as described.

2. A furnace consisting in combination of a grate composed of two parts, a front part inclined toward the rear and a horizontal part, a bridge above said horizontal part, transversely disposed in said furnace, a central main flue beneath said bridge and behind said grate, apertures in said bridge, lateral combustion-spaces beside said main flue with which the apertures in the bridge communicate, air-inlets for said combustion-spaces, air-inlets for the main flue, and an extended combustion-space in the rear of said first-named lateral combustion-spaces substantially as described.



809,323. FODDER LOADER AND HAULER. MARION PLACKARD, Orestes, Ind. Filed Aug. 14, 1905. Serial No. 274,944.



Claim.—1. A device of the kind described consisting of an oppositely-parallel-positioned pair of runners connected detachably each to the other and retained rigidly apart by transversely-extending bars formed curvilinearly downwardly, a rope loosely connected to the rear ends of said runners having its free ends adapted to be extended forwardly; means on the front ends of said runners for receiving the oppositely-extending portions of said rope and upon which the same may be fastened.

2. In a device of the kind described, the combination with a pair of runners, transversely-extending bars connecting the runners, of oppositely positioned and secured means at the rear ends of the runners for loosely retaining a rope, oppositely positioned and secured means at the front ends of the runners whereby the opposite ends of said rope being drawn diagonally transversely about the object to be bound, may be secured.

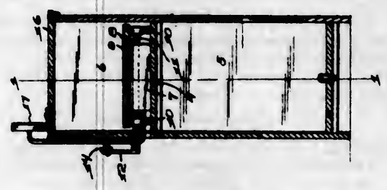
3. In a device of the kind described, the combination with a pair of runners, transversely-extending bars connecting and retaining apart said runners, of elbow-shaped joints for connecting the rear ends of said runners to said transversely-extending bars provided with apertures therein for the detachable connection of the same to the runners and with ears thereon formed integral therewith, and having eyes therein.

4. In a device of the kind described, the combination with a pair of runners, transversely-extending bars connecting and retaining apart said runners, of elbow-shaped joints for connecting the forward ends of said runners to said transversely-extending bars provided with apertures therein for the detachable connection of same to the runners, and having hooks thereon formed integral therewith.

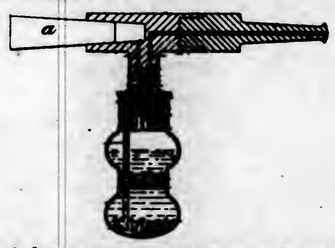
809,324. REFRIGERATOR. EDWARD PRENDERGAST, St. Louis, Mo. Filed Jan. 26, 1905. Serial No. 243,016.

Claim.—The improved weighing mechanism for refrigerators, comprising the combination of a refrigerator ice-chamber, a cooling-chamber, the platform 4 forming the bottom of said ice-chamber, and also forming the top of the said cooling-chamber; a common weighing-scale having the usual platform and casing 7 mounted upon the said platform 4; the water-shed 8 located above said scale; the vertically-movable ice-rack 9 mounted in the said ice-chamber above said water-shed and adapted to rest thereon; a series of eccentrics 10; shafts 11, upon which said eccentrics are mounted beneath said ice-rack 9 in order to raise and lower said ice-rack with relation

to the said water-shed, said shafts projecting outwardly through the rear wall of the said ice-chamber; crank-arms 12 and 13 fixed upon the projecting rear ends of said shafts, the connecting-rod 14 connecting said crank-arms, and a handle connected to the said crank-arm 13, substantially described.



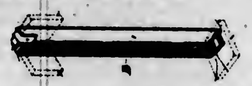
809,325. TOBACCO-PIPE, CIGAR-HOLDER, AND CIGARETTE-HOLDER. LESLIE PROBYN, Freetown, Sierra Leone. Filed Feb. 15, 1905. Serial No. 245,801.



Claim.—1. In an apparatus for smoking tobacco, the combination of a holder, a mouthpiece and passages leading from same, a plug having two passages therein, the upper ends of which are adapted in one position to coincide with the passages leading from the holder and mouthpiece, the lower ends of which lead to a liquid-chamber and cause the smoke to pass through the liquid, a cross-passage in said plug intermediate of the other two passages and adapted in one position to directly connect the passages leading from the holder and mouthpiece, a liquid-chamber carried by said plug and adapted to be turned and to assume two positions at right angles to each other, substantially as set forth.

2. In an apparatus for smoking tobacco, the combination of a holder, a mouthpiece, passages leading from said mouthpiece, a plug having two passages therein the upper ends of which are adapted in one position to register with the passages leading from the holder and mouthpiece the lower ends of which lead to a liquid-chamber and cause the smoke to pass through the liquid, a cross-passage in said plug intermediate of the other two passages and adapted in one position to directly connect the passages leading from the holder and mouthpiece, a liquid-chamber carried by said plug and adapted to be turned to assume two positions at right angles to each other and stops to limit the motion of said plug, substantially as described.

809,326. CRATE. WILLIAM H. REDMOND, Mount Pleasant, Mich. Filed July 8, 1905. Serial No. 268,762.

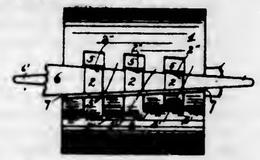


Claim.—1. A metallic corner-stay for a crate having its sides and ends formed of slats, said stay formed of a strip of sheet metal bent into the form of an angle-bar and provided with extensions at the upper end of the sides forming the angle of the bar which are adapted to be hooked over the top slats in the corners of the crate and with an extension adapted to fold on top of one of the aforesaid slats and interlock with the extension which hooks over said slat and thereby prevent the angle-bar from spreading out at the upper end.

2. A crate provided with metallic corner-stays formed of a metal strip bent into the form of an angle conforming to the corners of the crate and to which the ends of the slats forming the ends and sides of the crate are secured, said stay formed with extensions at the upper ends which are hooked over the top slats and are secured thereto and also with an extension engaging into the hook formed by one of the aforesaid extensions

3. A metallic corner-stay for a crate having its sides and ends formed of slats and secured to metallic stays at the corners of the crate, said stay formed of a strip of sheet metal bent to form an angle-bar conforming to the corners formed by the junction of the sides and ends of the crate and provided with extensions at the upper and lower ends, those at the upper end comprising the tongues *a b c* adapted to form an interlocked housing for the top slats in the manner described.

809,327. PIPE-CLAMP. EDWARD L. RIESER, Troy, Ohio, assignor to Gamaliel C. Myers, Dayton, Ohio. Filed Sept. 19, 1904. Renewed Nov. 27, 1905. Serial No. 289,946.

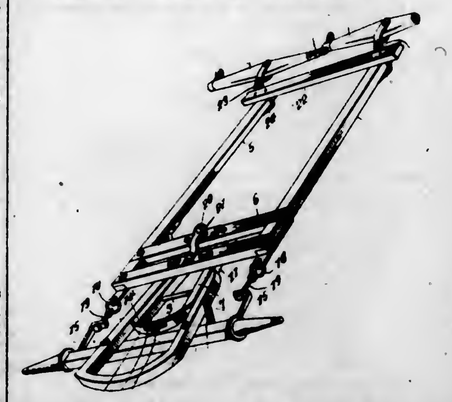


Claim.—1. A pipe-clamp having a series of loops in one portion thereof, the ends of said loops being integrally joined to said portion, and a corresponding series of slots into which said loops project, said slots having a series of adjacent parallel bars forming loops, a tapering wall lying on the outside of said slots, and a wedge-shaped key adapted to enter the loops on both portions of the clamp, and to draw said portions together as shown and described.

2. A clamp for stopping leak-holes in piping, consisting of a metallic band having a series of parallel loops stamped therein adjacent to one longitudinal edge thereof, and a series of parallel loops adjacent to the other longitudinal edge thereof with a series of intervening slots, a tapered wall extending throughout the length of the clamp, and an insertible key between the two series of loops and adapted to tighten said clamp by being confined on one side by said wall and on the other side by the inner terminals of the loops.

3. A clamp for stopping leak-holes in piping, having in one longitudinal edge thereof a series of stamped loops, the outer terminals of which extend on an angle to the body of the clamp, and the other longitudinal edge of said clamp having a series of parallel loops and slots inclosed at their outer terminals by a tapered wall extending throughout the length of the clamp, and a double tapered key adapted to pass between said loops and to draw the clamp together.

809,328. DRAFT-GEAR FOR VEHICLES. CHRISTIAN SHARER, Vandalia, Mich. Filed Mar. 7, 1905. Serial No. 248,894.



Claim.—1. The combination of a longitudinal draft-bar, a transverse draft-bar, spaced hounds connected at a point between their ends to the transverse draft-bar, and adjustable connections between opposite ends of said hounds.

2. The combination of an axle, draft-gear embodying a longitudinal draft-bar, a transverse draft-bar, spaced hounds projected from the transverse draft-bar for attachment to the axle, and con-

sections between the end portion of the transverse draft-bar and the axle.

3. The combination of an axle, draft-gear embodying a longitudinal draft-bar, a transverse draft-bar, spaced hounds projected from the transverse draft-bar for attachment to the axle, and adjustable connections between the end portions of the transverse draft-bar and the axle.

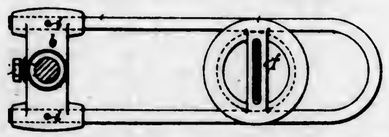
4. The combination of an axle, spaced longitudinal draft-bars, a transverse draft-bar connecting said longitudinal draft-bars, connecting means between the transverse draft-bar and the axle, an equalizing yoke device comprising a main yoke-bar attached to the longitudinal draft-bars, and short yoke-bars carried by the main yoke-bar.

5. The combination of spaced longitudinal draft-bars, a transverse draft-bar connecting the longitudinal draft-bars, an axle, spaced hounds projected from the transverse draft-bar and connected with the axle, and adjustable connections between the spaced hounds at opposite ends thereof.

6. The combination of spaced longitudinal draft-bars, a transverse draft-bar connecting the longitudinal draft-bars, an axle, spaced hounds projected from the transverse draft-bar and connected between the ends therewith, and adjustable connections between the opposite ends of the spaced hounds and comprising overlapping members.

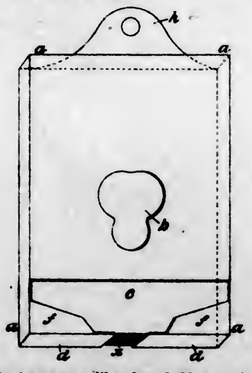
7. The combination of an axle, spaced longitudinal draft-bars, spaced transverse draft-bars, spaced hounds extending from the transverse draft-bars and adjustably connected therewith, adjustable connections between opposite ends of the spaced hounds aforesaid, hounds projected from the axle and connected with the spaced hounds aforesaid, and take-up connections between the opposite ends of one of the transverse draft-bars and the axle.

809,329. **BELT-SHIFTER.** FRIEDRICH W. SEYBOTH and ERNST K. A. BAUMANN, Zwickau, Germany. Filed June 13, 1905. Serial No. 264,865.



Claim.—A belt-shifter for step-pulleys, comprising a spindle, a belt-fork secured to said spindle, and a ring having a belt-guiding slot, said ring being exteriorly grooved to rotatably and slidably engage said fork.

809,330. **PAPER-HOLDER.** JOHN SIM, Liverpool, England. Filed Mar. 22, 1905. Serial No. 251,521.

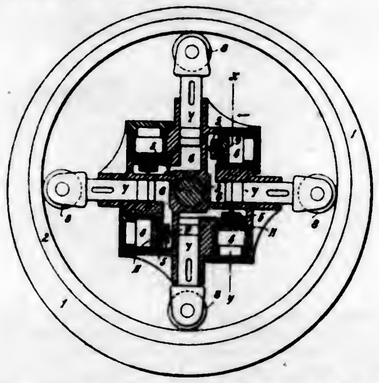


Claim.—1. A paper or like sheet holder consisting of a box, having an aperture at the lower part in front, and across same, for the withdrawal of the paper sheets; a gap or opening in the bottom of the box, extending into the front opening, for applying the thumb to the lower edges; front steps at each side of the lower opening, for holding the sheets at the front lower edges; and an opening above the withdrawal-opening for applying the finger to the front surface of the sheets; substantially as set forth.

2. A paper or like sheet holder consisting of a box having an opening in one side at the bottom thereof, steps *f*, *f* filling the lower corners of said opening, and an opening extending across the entire width of the bottom of the box in the center thereof, said opening communicating with the opening in the side, substantially as described.

3. A paper or like sheet holder consisting of a box having an opening in one side at the bottom thereof, and an opening in the central part of the bottom of the box, said opening extending from one side of the bottom to the other and communicating with the side opening, substantially as described.

809,331. **CLUTCH MECHANISM.** MICHELE G. DE SIMONE, London, England, assignor of three-eighths to Domenico Robert de Simone and one-fourth to The Wilkinson Sword Company Limited, both London, England. Filed Apr. 14, 1905. Serial No. 255,589.



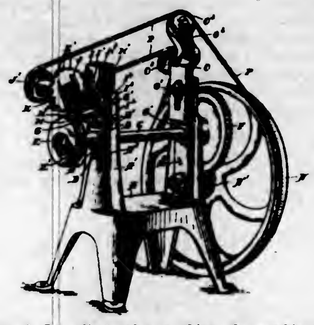
Claim.—1. In a liquid-clutch, the combination of a rotary clutch member having a circular recess eccentric to the axis of rotation, a second clutch member formed with radiating cylinders, plungers in said cylinders, the ends of which engage the inner face of said eccentric recess, a common liquid-chamber in communication with all the cylinders, a separate valve between each cylinder and the common liquid-chamber, and means for operating all the valves to allow the liquid to flow freely between the common liquid-chamber and the cylinders and the plungers to reciprocate in the latter under the action of the eccentric surface of the second clutch member, whereby the clutch will run idle, said means also serving to operate all the valves to close communication between the common liquid-chamber and the cylinders and lock the liquid therein and the plungers in rigid engagement with the eccentric surface of the second clutch member whereby both members are forced to rotate together.

2. In a liquid-clutch, the combination of an outer rotary clutch member having a circular recess eccentric to the axis of rotation, an inner rotary clutch member formed with radiating cylinders, plungers in said cylinders, the ends of which engage the inner face of said eccentric recess, a common liquid-chamber communicating through a separate and independent passage with each cylinder, a separate and independently self-adjusting valve controlling the respective passage between each cylinder and the common liquid-chamber, and means for operating all the valves in unison to allow the liquid to flow freely between the common liquid-chamber and the cylinders and the plungers to reciprocate in the latter under the action of the eccentric surface of the outer clutch member, whereby the clutch will run idle, said means also serving to operate all the valves in unison to close communication between the common liquid-chamber and the cylinders and lock the liquid therein and the plungers in rigid engagement with the eccentric surface of the outer clutch member whereby both members are forced to rotate together.

3. The improved clutch mechanism comprising a rotary clutch member having a circular recess eccentric to the axis of rotation, another rotary clutch member formed with radially-disposed cylinders, plungers in said cylinders, the ends of which engage the inner face of said eccentric recess, a common liquid-chamber in communication with all the cylinders, valves between said cylinders and the common liquid-chamber, means for operating said valves whereby the liquid may be allowed to run freely between the cylinders, and the plungers to reciprocate therein under the action of the eccentric

surface of the other member of the clutch, whereby the clutch will run free, said means also serving to operate said valve to close communication between the cylinders and lock the liquid therein and the plungers in rigid engagement with the eccentric surface of the other member of the clutch whereby both members rotate together.

809,332. **LIP-TURNER.** FRANK F. SMITH, Detroit, Mich., assignor to The Robert Mitchell Machinery Co., Detroit, Mich., a Corporation of Michigan. Filed May 10, 1902. Renewed Nov. 4, 1904. Serial No. 231,356.



Claim.—1. In a lip-turning machine, the combination with means for supporting and feeding the work, of a wiper-wheel revolving in a plane at right angles to the path of the lip and having peripheral wiper-teeth traversing the path of the lip.

2. In a lip-turning machine, the combination with means for supporting and feeding the work, of a wiper-wheel revolving in a plane at right angles to the path of the lip and having peripheral wiper-teeth traversing the path of the lip above the surface of the work.

3. In a lip-turning machine, the combination with means for supporting and feeding the work, of a revolving wiper-wheel operating in a plane at right angles to the path of the lip for turning the lip and a presser for setting the lip after passing the wiper-wheel.

4. In a lip-turning machine, the combination with means for supporting and feeding the work, of a lip-raising tool, a wiper-wheel traversing the path of the lip for turning the lip and a presser-roll for setting the lip.

5. In a lip-turning machine, a revolving wiper-wheel in a plane at right angles to the path of the lip and having wiper-teeth formed with rounded-off contact-faces for striking the lip above its base and turning the same.

6. In a lip-turning machine, the combination with means for supporting and feeding the work, of a wiper-wheel revolving in a plane at right angles to the path of the lip and adapted to turn the lip by a wiping contact therewith and means for holding the work in position against such contact.

7. In a lip-turning machine, in combination with the frame thereof, a lip-raising tool mounted upon the frame, a wiper-wheel revolvable in a plane at right angles to the path of the lip and adjacent to said tool, a presser-roll adjustably secured to said frame and extending longitudinally across the path of the lip, a work-supporting wheel revolvable in a vertical plane, and means for yieldingly holding said wheel in contact with the work to clamp the same between the tool and the wheel.

8. In a lip-turning machine, in combination with the frame thereof, a horizontal shaft mounted in movable bearings on said frame, a work supporting and feeding wheel on said shaft, a lip-raising guide adjustably secured on said frame, means for yieldingly supporting the shaft to clamp the work between the wheel and said guide, a bracket adjustably secured to the frame, a shaft mounted on said bracket, a wiper-wheel on said shaft adjacent to the guide, and a presser-roll adjacent to the wiper-wheel.

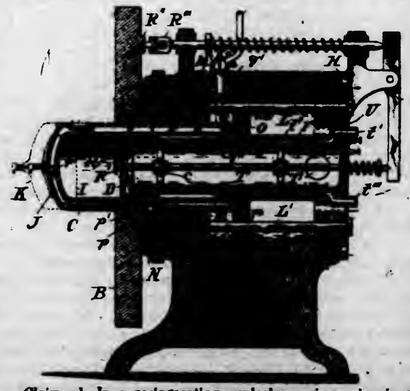
9. In a lip-turning machine, in combination with the frame thereof having vertical ways, a bearing-block mounted on said ways, a shaft extending longitudinally of the frame and journaled and supported at one end on said block, a work supporting and feeding wheel on said shaft, a lip-raising guide on said frame extending over said wheel, a spring engaging said bearing-block to yieldingly clamp the work between the wheel and the guide, means for depressing said spring to lower the wheel, a bracket secured to the frame, a shaft mounted in a bearing on said bracket, a wiper-wheel revolving in a plane at right angles to the path of the lip and secured on the end of said shaft, and a bracket adjustably mounted on the frame adjacent to the wiper-wheel and provided with a presser-roll extending across the path of the lip at right angles thereto.

10. In a lip-turning machine, in combination with the frame thereof, a bearing-block movable in verical ways on said frame and a bearing-block secured in an opening in said frame and free to tilt therein, a horizontal shaft mounted in said bearings, a work supporting and feeding wheel on said shaft, a lip-raising guide on said frame, a spring engaging the lower side of the movable bearing-block to hold the feed-wheel in contact with the work to clamp the same between the wheel and said guide, an adjusting-plug engaging the lower end of said spring, means for adjusting and holding said plug, a rod secured to said movable block to move the same on its ways, nd a wiper-wheel adjacent to the lip-raising guide revolving at right angles to the path of the lip.

11. In a lip-turning machine, in combination with the frame thereof having a vertical standard at each end thereof, one standard being provided with an opening and the other with vertical ways, a bearing-block in said opening and a bearing-block movable on said ways, a horizontal shaft mounted on said blocks, a work supporting and feeding wheel on said shaft, stops adapted to be engaged by the block on said ways, a coil-spring engaging the lower side of said block at one end, an adjusting-plug projecting through an opening in said frame and engaging the lower end of said spring and provided with an axial opening, means for adjusting said plug in the opening, a rod secured to the lower side of the block on the ways and extending downward through the spring and the opening in the plug, a lip-raising guide adjustably secured to the frame, a wiper-wheel revolving at right angles to the path of the lip and adjacent to the guide, a bracket adjustably secured to the frame, and a pressure-roll journaled on said bracket adjacent to the wiper-wheel.

12. In a lip-turning machine, in combination with the frame thereof having vertical standards, a horizontal shaft mounted in movable bearings on said standards, a work feeding and supporting wheel secured on said shaft, a supporting-block adjustably secured to one of the standards, a lip-raising guide provided with a slot and adjustably secured to said block by a screw passing through said slot, a bracket adjustably secured to the block, a presser-roll journaled on said bracket and extending longitudinally across the path of the lip, a bracket adjustably secured to the standard, a shaft mounted in a bearing on said last-named bracket, and a wiper-wheel secured to one end of the last-named shaft and revolving in a plane at right angles to the path of the lip and between the lip-raising guide and the presser-roll.

809,333. **CAM-MOVEMENT EXPLOSIVE-ENGINE.** PHILIP K. STEES, New York, N. Y. Filed Jan. 22, 1903. Serial No. 140,067.



Claim.—1. In a reciprocating explosive-engine, wherein the motion of the reciprocating element actuated by an energized power medium, is adapted to be translated into a rotary motion at its fly-wheel, a kinematic connection between the fly-wheel and the reciprocating element located within the hub of the fly-wheel, for converting the motion of the reciprocating element into a relatively constant rotatory motion of the fly-wheel and conversely for transforming a constant rotatory motion of the fly-wheel into a periodic recip-

rocating motion of the reciprocating element, together with suitable valve mechanism for controlling the working fluid for said engine, actuated by said fly-wheel, substantially as described.

2. In a reciprocating explosive-engine, wherein the motion of the reciprocating element actuated by an energized power medium is adapted to be translated into a rotary motion at its fly-wheel, a kinematic connection between the fly-wheel and the reciprocating element located within the hub of the fly-wheel, for converting the motion of the reciprocating element into a relatively constant rotatory motion of the fly-wheel and conversely for transforming a constant rotatory motion of the fly-wheel into a periodic reciprocating motion of the reciprocating element, a circulating fluid between said reciprocating element and said fly-wheel, and a valve for controlling the working fluid for said engine, together with means coacting between said fly-wheel and said valve for actuating the latter upon the rotation of the said fly-wheel substantially as described.

3. In an explosive-engine having a reciprocating power element actuated by an energized power medium and a rotatory member therefor, a kinematic connection between the reciprocating power element and the rotatory member located at a point radiating from the axis of rotation of the rotatory member, for translating the motion of the reciprocating power element into a relatively constant rotatory motion of the rotatory member and conversely for transforming a constant rotatory motion of the rotatory member into a periodic reciprocating motion of the reciprocating power element, a circulating fluid between the said reciprocating power element and said rotatory member, and a reciprocating valve for controlling the working fluid for the said engine, together with means coacting between said rotatory member and said valve for actuating the latter upon the rotation of the said rotatory member; substantially as described.

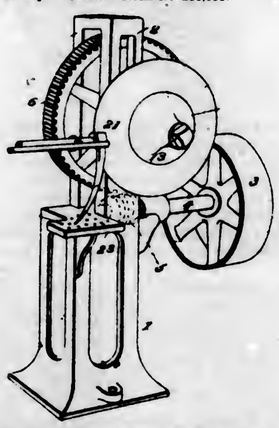
4. In an explosive-engine having a reciprocating power element actuated by an explosive mixture and a rotatory member therefor adapted to revolve about said reciprocating power element, a kinematic connection between the reciprocating power element and the rotatory member located at a point radiating from the axis of rotation of the rotatory member, for translating the motion of the reciprocating power element into a relatively constant rotatory motion of the rotatory member and conversely for transforming a constant rotatory motion of the rotatory member into a periodic reciprocating motion of the reciprocating power element, a circulating fluid between said reciprocating power element and said rotatory member, a reciprocating valve for controlling the working fluid for said engine, together with means coacting between said rotatory member and said valve for actuating the latter upon the rotation of the said rotatory member and means for igniting said explosive mixture.

5. In an explosive-engine comprising a combustion-chamber having a reciprocating power element actuated by an explosive mixture confined in said combustion-chamber and a rotatory member adapted to revolve about said reciprocating power element, a kinematic connection between the reciprocating power element and the rotatory member located at a point radiating from the axis of rotation of the rotatory member and exterior to said cylinder, for translating the motion of the reciprocating power element into a relatively constant rotatory motion of the rotatory member and conversely for transforming a constant rotatory motion of the rotatory member into a periodic motion of the reciprocating power element, a circulating fluid between said reciprocating power element and said rotatory member, a reciprocating valve for controlling the working fluid for said engine, together with means coacting between said rotatory member and said valve for actuating the latter upon the rotation of the said rotatory member and means located within the cylinder for igniting said explosive mixture.

6. In an explosive-engine, comprising a combustion-chamber having a reciprocating power element actuated by an explosive mixture confined in said combustion-chamber and a rotatory member adapted to revolve about said reciprocating power element, a kinematic connection between the reciprocating power element and the rotatory member located in an arc radiating from the axis of rotation of the rotatory member and concentric with the exterior of said cylinder, for translating the motion of the reciprocating power element into a relatively constant rotatory motion of the rotatory member and conversely for transforming a constant rotatory motion of the rotatory member into a periodic reciprocating motion of the reciprocating power element, a circulating fluid between said reciprocating power element and said rotatory member, a reciprocating valve for controlling the working fluid for said engine, together with means coacting between said rotatory member and said valve for actuating the latter upon the rotation of the said rotatory member and means located within the cylinder for igniting the explosive mixture.

7. In an explosive-engine comprising a combustion-chamber having a reciprocating power element actuated by an explosive mixture confined within said chamber and a rotatory member adapted to revolve about said reciprocating power element, said reciprocating power element adapted to vibrate along an axial line coincident with the axis of rotation of the rotatory member, a kinematic connection between the reciprocating power element and the rotatory member, for translating the motion of the reciprocating power element into a relatively constant rotatory motion of the rotatory member and conversely for transforming a constant rotatory motion of the rotatory member into a periodic reciprocating motion of the reciprocating power element, a circulating fluid, and inlet and outlet pipe connections therefor, located between said reciprocating power element and said rotatory member, inlet and exhaust valves for controlling the working fluid for said engine, together with means coacting between said rotatory member and said exhaust-valve for actuating the latter upon the rotation of the said rotatory member and means for igniting said explosive mixture.

809,334. DISK-SHARPENER. CHARLES M. STRAIN, Crawfordsville, Iowa, assignor of one-third to Davidson Bros., Crawfordsville, Iowa. Filed Apr. 17, 1905. Serial No. 256,096.



Claim.—1. In a disk-sharpener, the combination of a power-driven shaft provided with a clamp member having its outer face provided with a centrally-disposed recess and with a circular series of spaced projections, a coöperating clamp member loose upon said shaft and having recesses in its inner face to receive the projections of the first-mentioned clamp member and provided in its outer face with a depression to receive the hub of the disk to be sharpened, a means acting jointly with the said clamp members for holding them and the work securely.

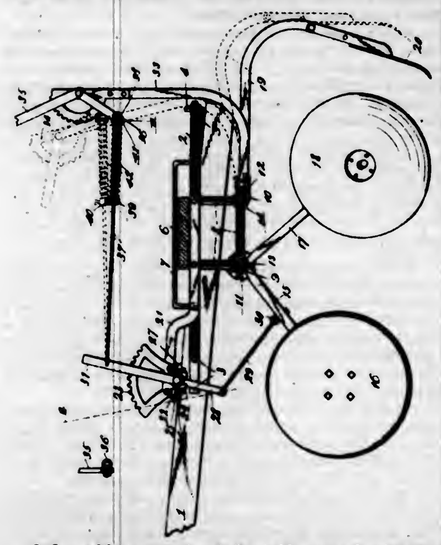
2. A holder for disk-sharpeners provided with a supporting-standard curved in its length to admit of the disk to be sharpened occupying a position between parallel planes passed through respectively, the edge of the tool and the foot of the standard, whereby the normal tendency of the tool is to fall away from the disk.

3. A tool-holder for disk-sharpeners comprising members pivoted between their ends, one of said members having a pressure-roller and the other provided with a tool and with an integral standard curved and tapered throughout its length to a point, the parts being arranged to admit of the disk to be sharpened occupying a position between parallel planes passed through respectively the edge of the tool and the foot of the standard, whereby the normal tendency of the tool is to fall away from the disk.

809,335. CULTIVATOR. HERMAN S. SWANSON, Shenandoah, Iowa, assignor to Swanson Mfg. Co., of Iowa. Filed Dec. 15, 1904. Serial No. 236,944.

Claim.—1. In a cultivator, a rocker-shaft suitably mounted, cultivating appliances suitably secured thereto, a crank-arm also secured to the rocker-shaft, a segment secured to said crank-arm, a hand-lever fulcrumed upon the segment, means for locking said hand-lever and segment together, and means engaging the hand-lever against which the latter is arranged to push.

2. In a cultivator, a rocker-shaft suitably mounted, cultivating appliances suitably secured thereto, a right-angled crank-arm also secured to the rocker-shaft, a segment secured to said crank-arm, a hand-lever fulcrumed upon the segment, means for locking said hand-lever and segment together, and means engaging the hand-lever against which the latter is arranged to push.



3. In a cultivator, a rocker-shaft suitably mounted, cultivating appliances suitably secured thereto, a crank-arm also secured to the rocker-shaft, a segment secured to said crank-arm, a hand-lever fulcrumed upon the segment, means for locking said hand-lever and segment together, and a connecting-rod suitably secured at its forward end and loosely secured at its rear end to said hand-lever.

4. In a cultivator, a rocker-shaft suitably mounted, cultivating appliances suitably secured thereto, a crank-arm also secured to the rocker-shaft, a segment secured to said crank-arm, a hand-lever fulcrumed upon the segment, means for locking said hand-lever and segment together, a connecting-rod suitably secured at its forward end and loosely secured at its rear end to said hand-lever, and a coil-spring embracing said connecting-rod and pressing against the hand-lever.

5. In a cultivator, a rocker-shaft suitably mounted, cultivating appliances suitably secured thereto, a crank-arm also secured to the rocker-shaft, a segment secured to said crank-arm, a hand-lever fulcrumed upon the segment, a connecting-rod suitably secured at its forward end and loosely engaging the hand-lever with its rear end, a collar adjustably secured to said connecting-rod, and an expansion-spring embracing the connecting-rod and interposed between said collar and the hand-lever.

6. In a cultivator, a rocker-shaft suitably mounted, cultivating appliances suitably secured thereto, a crank-arm also secured to the rocker-shaft, a segment secured to said crank-arm, a hand-lever fulcrumed upon the segment, an eyebolt swiveled on the lever, a connecting-rod suitably secured at its forward end and having its rear end extending through the eyebolt, and means for preventing the accidental withdrawal of the connecting-rod from said eyebolt.

7. In a cultivator, two rocker-shafts suitably mounted, cultivating appliances suitably secured thereto, a primary lever fulcrumed upon the cultivator, means connecting said lever to one of said rocker-shafts, a crank-arm secured to the other rocker-shaft, a segment secured to said crank-arm, a secondary hand-lever fulcrumed upon said segment, and a connecting-rod pivotally secured at one end to one of the levers and loosely secured at its opposite end to the other lever.

8. In a cultivator, two rocker-shafts suitably mounted, cultivating appliances suitably secured thereto, a primary lever fulcrumed upon the cultivator, means connecting said lever to one of said rocker-shafts, a segment located beside said primary lever, a longitudinal brace to which said segment is secured, a crank-arm secured to the other rocker-shaft, a segment secured to said crank-arm, a secondary hand-lever fulcrumed upon said segment, and a connecting-rod pivotally secured at one end to one of the levers, and loosely secured at its opposite end to the other lever.

9. In a cultivator, two rocker-shafts suitably mounted, cultivating appliances secured to one of said rocker-shafts, a primary lever fulcrumed upon the cultivator, means connecting said lever to one of said rocker-shafts, wheel-arms secured to one of said shafts, a crank-arm secured to the other rocker-shaft, a secondary hand-lever fulcrumed upon said crank-arm, means for locking said hand-lever to said crank-arm when desired, and a connecting-rod pivotally secured at one end to one of the levers, and loosely secured at its opposite end to the other lever.

10. In a cultivator, two rocker-shafts, one of which is mounted in advance of the other, cultivating appliances suitably secured to one of said shafts, wheel-arms secured to one of said shafts, a transverse shaft mounted upon the cultivator, crank-arms secured to the transverse shaft, a primary hand-lever also secured to the transverse shaft, means connecting the crank-arms to the wheel-arms, a crank-arm secured to the other rocker-shaft, a segment secured to said crank-arm, a secondary hand-lever fulcrumed upon said segment, and a connecting-rod pivotally secured at one end to one of the levers and slidably secured at its opposite end to the other lever.

11. In a cultivator, two rocker-shafts suitably mounted, cultivating appliances suitably secured to one of said shafts, wheel-arms secured to one of said shafts, a crank-arm secured to one of said shafts, a primary lever fulcrumed upon the cultivator, means connecting said lever to the other shaft, and suitable means connecting the crank-arm to said primary lever whereby both may be simultaneously operated or the crank-arm may be operated independently of the primary lever.

12. In a cultivator, two rocker-shafts suitably mounted, cultivating appliances secured thereto, a crank-arm secured to one of said shafts, a primary lever fulcrumed upon the cultivator, means connecting said lever to the other shaft, and resilient means connecting the crank-arm to said primary lever whereby both may be simultaneously operated or the crank-arm may be operated independently of the primary lever.

13. In a cultivator, two rocker-shafts suitably mounted, cultivating appliances secured thereto, a crank-arm secured to one of said shafts, a primary lever fulcrumed upon the cultivator, means connecting said lever to the other shaft, resilient means connecting the crank-arm to said primary lever whereby both may be simultaneously operated or the crank-arm may be operated independently of the primary lever, and means for regulating the tension of said resilient connections.

14. In a cultivator, two rocker-shafts suitably mounted, cultivating appliances secured thereto, a crank-arm secured to one of said shafts, a secondary hand-lever fulcrumed upon said crank-arm, means for locking said lever to the crank-arm when desired, a primary lever fulcrumed upon the cultivator, means connecting said lever to the other shaft, and suitable means connecting the secondary lever to the primary lever whereby both may be simultaneously operated or the secondary lever may be operated independently of the primary lever.

15. In a cultivator, two rocker-shafts suitably mounted, cultivating appliances secured thereto, a crank-arm secured to one of said shafts, a secondary hand-lever fulcrumed upon said crank-arm, means for locking said lever to the crank-arm when desired, a primary lever fulcrumed upon the cultivator, means connecting said lever to the other shaft, and resilient means connecting the secondary lever to the primary lever whereby both may be simultaneously operated or the secondary lever may be operated independently of the primary lever.

16. In a cultivator, two rocker-shafts suitably mounted, cultivating appliances secured thereto, a crank-arm secured to one of said shafts, a secondary hand-lever fulcrumed upon said crank-arm, means for locking said lever to the crank-arm when desired, a primary lever fulcrumed upon the cultivator, means connecting said lever to the other shaft, resilient means connecting the secondary lever to the primary lever whereby both may be simultaneously operated or the secondary lever may be operated independently of the primary lever, and means for regulating the tension of the resilient connections.

17. In a cultivator, an octagonal frame, bearings depending from said frame, rocker-shafts mounted in said bearings, cultivating appliances suitably secured to said shafts, a primary lever fulcrumed upon the cultivator, means connecting said lever to one of said shafts, a right-angled crank-arm secured to the other shaft and

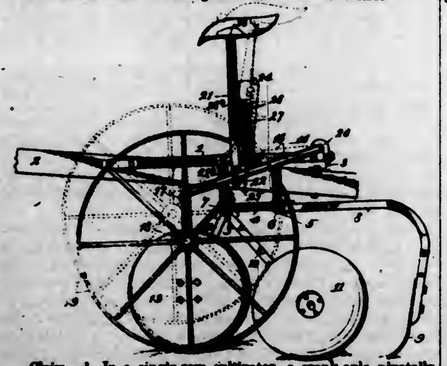
extending upwardly and backwardly to the rear of the frame, a secondary lever fulcrumed upon said crank-arm, means for locking said secondary lever to the crank-arm when desired, and a connecting-rod pivotally secured at one end to one of the levers and loosely secured at its opposite end to the other lever.

18. In a cultivator, an octagonal frame, bearings depending from said frame, rocker-shafts mounted in said bearings, cultivating appliances secured to one of said shafts, a crank-arm suitably secured to one of said shafts, a secondary hand-lever fulcrumed upon said crank-arm, means for locking said secondary lever to the crank-arm, a primary lever fulcrumed upon the cultivator, means connecting said lever to the other shaft, and a connecting-rod pivotally secured at one end to one of the levers and loosely secured at its opposite end to the other lever.

19. In a cultivator, two rocker-shafts one of which is mounted in advance of the other, cultivating appliances suitably secured thereto, wheel-arms also secured to the forward shaft, a transverse shaft suitably mounted, crank-arms secured thereto, draft-rods connecting said crank-arms to the wheel-arms, a primary lever also secured to the transverse shaft, a crank-arm secured to the rear rocker-shaft, a segment secured to said crank-arm, a secondary lever fulcrumed upon said segment, and a connecting-rod pivotally secured at one end to the primary lever and loosely secured at its opposite end to the other lever.

20. In a cultivator, two rocker-shafts one of which is mounted in advance of the other, cultivating appliances suitably secured thereto, wheel-arms also secured to the forward rocker-shaft, a forwardly-extending longitudinal brace suitably secured at its rear end to the frame of the machine, a transverse brace secured at its opposite ends to the forward end of the longitudinal brace and the tongue of the machine, a segment secured to the longitudinal brace and provided with a bearing, a transverse shaft journaled at one end in said bearing and at its opposite end in a bearing upon the tongue, depending crank-arms secured to said transverse shaft, draft-rods connecting said depending crank-arms to the wheel-arms, a primary lever rigidly secured to the transverse shaft adjacent to the segment, a crank-arm secured to the rear rocker-shaft, a segment secured to said crank-arm, a secondary lever fulcrumed upon said segment, and a connecting-rod pivotally secured at one end to one of the levers and loosely secured at its rear end to the other lever.

809,886. SINGLE-ROW CULTIVATOR. HERMAN S. SWANSON, Shenandoah, Iowa. Filed Aug. 20, 1905. Serial No. 276,220.



Claim.—1. In a single-row cultivator, a crank-axle pivotally mounted upon the cultivator, balancing-wheels mounted upon the free ends of said crank-axle, yielding means for normally limiting the upward movement of said balancing-wheels, and means for positively limiting said upward movement.

2. In a single-row cultivator, a crank-axle pivotally mounted upon the cultivator, balancing-wheels mounted upon the free ends of said crank-axle, a spring for normally limiting the upward movement of said balancing-wheels, and means for positively limiting said upward movement.

3. In a single-row cultivator, a crank-axle pivotally mounted upon the cultivator, balancing-wheels mounted upon the free ends of said crank-axle, yielding means for normally limiting the upward movement of said balancing-wheels, and a cable for positively limiting said upward movement.

4. In a single-row cultivator, a crank-axle pivotally mounted upon the cultivator, balancing-wheels mounted upon the free ends of said crank-axle, yielding means for normally limiting the upward movement of said balancing-wheels, and adjusting means for positively limiting said upward movement.

5. In a single-row cultivator, a crank-axle pivotally mounted upon the cultivator, balancing-wheels mounted upon the free ends of said crank-axle, adjustable yielding means for normally limiting the upward movement of said balancing-wheels, and means for positively limiting said upward movement.

6. In a single-row cultivator, a crank-axle pivotally mounted upon the cultivator, balancing-wheels mounted upon the free ends of said crank-axle, a member carried by said crank-axle, a cable attached at its ends to the cultivator and said member for positively limiting the upward movement of the balancing-wheels, and yielding means secured to said cable for normally limiting said upward movement.

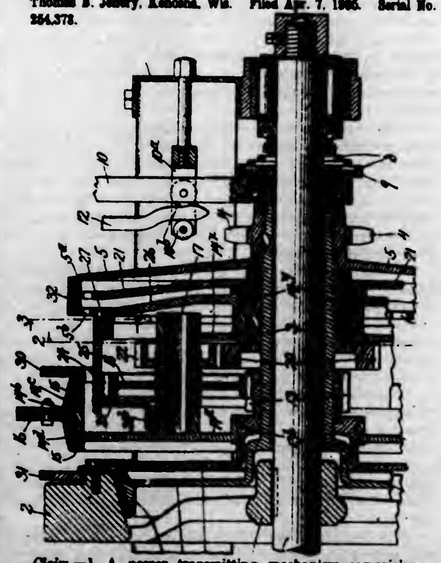
7. In a single-row cultivator, a pair of guide-wheels upon which said cultivator is mounted, a crank-axle pivotally mounted upon the cultivator, balancing-wheels mounted upon the free ends of said crank-axle, said guide-wheels and balancing-wheels having independent vertical movement, yielding means for normally limiting said independent movement, and means for positively limiting said movement.

8. In a cultivator, the combination with a tongue, a frame mounted thereon, cultivating appliances suitably secured to said frame, and guide-wheels upon which said frame is mounted, of a crank-axle pivotally mounted upon the frame, balancing-wheels mounted upon the free ends of said crank-axle, said guide-wheels and balancing-wheels having independent vertical movement, yielding means for normally limiting said independent movement, and means for positively limiting said movement.

9. In a single-row cultivator, a crank-axle pivotally mounted upon the cultivator, balancing-wheels mounted upon said crank-axle, a seat-bracket mounted upon the crank-axle, a cable attached at its ends to the seat-bracket and the cultivator, and a spring secured at its ends to said cable, substantially as described.

10. In a single-row cultivator, a crank-axle pivotally mounted upon said cultivator, balancing-wheels mounted upon said crank axle, a seat-bracket adjustably mounted upon said crank-axle, a cable adjustably attached at one end to the seat-bracket and attached at its opposite end to the cultivator, said cable having a suitable amount of slack, and a spring adjustably secured to the ends of said slack portion, substantially as described.

809,887. POWER-TRANSMITTING MECHANISM FOR MOTOR-VEHICLES. ROBERT SYMONDS, Jr., Kenosha, Wis., assignor to Thomas B. Jeffery, Kenosha, Wis. Filed Apr. 7, 1905. Serial No. 254,373.



Claim.—1. A power-transmitting mechanism comprising a power-shaft and power-wheel thereon; a power-transmitting wheel loose on the power-shaft and disengageably engageable with the power-wheel; a gear rigid with the power-wheel and a speed-reducing gear-train therefrom to the power-transmitting wheel; a frame for carrying the intermediate gear-train which is mounted rotatably about the power-shaft, and means for holding such frame against rotation.

2. A power-transmitting mechanism comprising a power-shaft and a power-wheel thereon; a power-transmitting wheel loose on the power-shaft and disengageably engageable with the power-wheel; a gear rigid with the power-wheel, and a direction-reversing gear-train therefrom to the power-transmitting wheel; a frame for carrying the intermediate gears of the train which is mounted rotatably about the power-shaft, and means for holding such frame against rotation.

3. A power-transmitting mechanism comprising a power-shaft and a power-wheel thereon; a power-transmitting wheel loose on the power-shaft and disengageably engageable with the power-wheel; a gear rigid with the power-wheel; a gear-train operated by said gear comprising two oppositely-rotating elements both journaled about the power-shaft; means rigid with the power-transmitting wheel adapted for engagement with each of said oppositely-rotated elements, and means for moving said elements at will into and out of such engagement.

4. A power-transmitting mechanism comprising a power-shaft and a power-wheel thereon; a power-transmitting wheel loose on the power-shaft and disengageably engageable with the power-wheel; a gear rigid with the power-wheel; a gear-train operated by said gear comprising two differently-speeded elements; means rigid with the power-transmitting wheel adapted for engagement with each of said differently-speeded elements, and means for moving said elements at will into and out of such engagement.

5. A power-transmitting mechanism comprising a power-shaft and a power-wheel thereon; a power-transmitting wheel loose on the power-shaft disengageably engageable with the power-wheel; a gear rigid with the power-wheel and a speed-reducing and direction-reversing gear-train therefrom to the power-transmitting wheel; a gear-frame for carrying the intermediate gears of the train which is mounted rotatably about the power-shaft, and means for holding such frame against rotation.

6. A power-transmitting mechanism comprising a power-shaft and a power-wheel thereon; a power-transmitting wheel loose on the power-shaft and disengageably engageable with the power-wheel; a gear rigid with the power-wheel; a gear-train operated by said gear comprising two oppositely-rotated and differently-speeded elements both journaled about the power-shaft; means rigid with the power-transmitting wheel adapted for engagement with each of said oppositely-rotated and differently-speeded elements, and means for moving said elements at will into and out of such engagement.

7. A power-transmitting mechanism comprising a power-shaft and a power-wheel thereon; a power-transmitting wheel loose on the power-shaft disengageably engageable with the power-wheel; a gear rigid with the power-wheel; a gear-train operated by said gear comprising two oppositely-rotated elements both journaled about the power-shaft; means rigid with the power-transmitting wheel adapted for engagement with each of said oppositely-rotated elements; a frame by which said gear-train is carried, and means for moving the frame at will to carry said oppositely-rotated elements into and out of such engagement.

8. A power-transmitting mechanism comprising a power-shaft and a power-wheel thereon; a power-transmitting wheel loose on the power-shaft and disengageably engageable with the power-wheel; a gear rigid with the power-wheel; a gear-train operated by said gear comprising two oppositely-rotated elements both journaled about the power-shaft; means rigid with the power-transmitting wheel adapted for engagement with each of said oppositely-rotated elements; a frame on which said gear-train is carried mounted for rotation about the power-shaft; means for moving it at will to carry said oppositely-rotated elements into and out of engagement with the power-transmitting wheel and for holding said frame against rotation at both limits of such movement.

9. A power-transmitting mechanism comprising a power-shaft and a power-wheel thereon; a power-transmitting wheel having a sleeve by means of which it is journaled loose on the power-shaft, and disengageably engageable with the power-wheel; a gear rigid with the power-wheel; a gear-train comprising a spur-wheel and an internal gear both journaled about the sleeve, and gear connections extending from the gear which is rigid with the power-wheel, both to the spur-gear and to the internal gear for communicating to them respectively opposite rotation, the spur-gear and the internal gear having each rigid with it an element adapted for driving engagement, the power-transmitting wheel having means for such engagement; a frame in which the gear-train is carried movable longitudinally with respect to the power-shaft for carrying said elements into and out of engagement with the power-transmitting wheel.

10. A power-transmitting mechanism comprising a power-shaft and a power-wheel thereon; a power-transmitting wheel loose on the power-shaft and disengageably engageable with the power-wheel; a gear rigid with the power-wheel; a gear-train therefrom to the power-transmitting wheel comprising two oppositely-rotated elements each adapted for engagement with the power-transmitting wheel, the power-transmitting wheel having rigid with it a brake-flange, said brake-flange having the means for engagement with said oppositely-rotated elements of the gear-train; the frame on which the gear-train is carried being movable longitudinally with respect to the shaft to carry said elements into and out of such engagement

11. A power-transmitting mechanism comprising a power-shaft and a power-wheel thereon; a power-transmitting wheel loose on the power-shaft and disengageably engageable with the power-wheel; a gear rigid with the power-wheel, and a gear-train therefrom to the power-transmitting wheel comprising an element adapted to be moved into and out of engagement with the power-transmitting wheel; a frame on which the gear-train is carried mounted for rotation about the power-shaft, movable longitudinally with respect thereto for carrying said element into and out of such engagement with the power-transmitting wheel, said gear-carrying frame having a friction-flange; means mounted on the main frame for engagement with such friction-flange to hold the frame against rotation, such means being movable longitudinally with respect to the shaft for carrying the gear-frame longitudinally, and a stop on the main frame which arrests such movement of the gear-frame

12. A power-transmitting mechanism comprising a power-wheel and a gear rigid therewith; a gear-train operated by said gear comprising two oppositely-rotated elements both journaled about the axis of the power-wheel; a power-transmitting wheel adapted for engagement with each of said oppositely-rotated elements, and a frame in which said gear-train is carried mounted for rotation about the axis of the power-wheel and for movement at will longitudinally with respect thereto to carry said oppositely-rotated elements into and out of such engagement, said frame having two friction-faces; a friction-shoe mounted on the frame for encounter with said faces respectively by movement in opposite directions; said shoe being adapted to be moved to engage and move the gear-frame, and stops on the main frame for limiting the movement of the gear-frame in said opposite directions.

13. A power-transmitting mechanism comprising a power-shaft and a power-wheel thereon; a power-transmitting sleeve on the shaft having a clutch member and means for power-transmitting engagement with said wheel; a gear rigid with the wheel concentric with the shaft exterior to the sleeve; a gear-train comprising a spur-wheel and an internal gear, both journaled about the sleeve, and gear connections extending from the first-mentioned gear both to the spur-gear and to the internal gear for communicating to the latter respectively opposite rotation, the spur-gear and the internal gear each having a clutch member, the bearing-support for said gear being movable longitudinally with respect to the shaft for carrying the clutch members of said gears into and out of engagement with the clutch member on the sleeve.

14. A power-transmitting mechanism comprising a power-shaft and a power-wheel thereon; a power-transmitting sleeve journaled on the shaft having power-transmitting engagement with the wheel and movable longitudinally on the shaft to engage it with and disengage it from the wheel; a gear concentric with the shaft outside the sleeve having rigid connection with the wheel; a gear-train connecting said gear with the sleeve comprising a spur-gear journaled about the sleeve; an internal gear also journaled thereabout, and intermediate gears communicating power from the first-mentioned gear to said spur-gear and internal gear respectively; a clutch member on the sleeve and clutch members on said spur-gear and internal gear respectively for engagement with the clutch member on the sleeve; means for moving the sleeve into and out of engagement with the wheel and means for moving the gear clutch members into and out of engagement respectively with the sleeve clutch member.

15. A power-transmitting mechanism comprising a power-shaft; a wheel fast thereon for rotation; a power-transmitting sleeve on the shaft; means for engaging it with and disengaging it from the wheel; a gear concentric with the shaft exterior to the sleeve and rigidly connected with the wheel for rotation; a gear-carrying frame mounted for rotation about the shaft; a gear-train carried by said frame of which the first wheel is engaged with the first-mentioned gear, and which comprises a wheel having a clutch member; a cooperating

clutch member on the sleeve and means for holding the gear-frame against rotation.

16. A power-transmitting mechanism comprising a power-shaft and a power-wheel thereon; a power-transmitting sleeve on the shaft having disengageable power-transmitting engagement with the wheel; a gear concentric with the shaft exterior to the sleeve, rigid with the wheel; another gear journaled about the shaft having a clutch member; gear connections from the first-mentioned gear to the second; a frame on which said intermediate gear connections are carried mounted for rotation about the shaft, and means for holding said frame against rotation.

17. A power-transmitting mechanism comprising a power-shaft; a power-transmitting wheel loose on the power-shaft; a gear rigid with said shaft, and a speed-reducing gear-train intermediate said rigid gear and power-transmitting wheel; a frame for carrying said intermediate gear-train which is mounted rotatably about the power-shaft, and means for holding such frame against rotation.

18. A power-transmitting mechanism comprising a power-shaft; a power-transmitting wheel loose on the power-shaft; a gear rigid with the power-shaft and a motion-reversing train intermediate said rigid gear and the power-transmitting wheel; a frame for carrying the intermediate gear-train which is mounted rotatably about the power-shaft, and means for holding such frame against rotation.

19. A power-transmitting mechanism comprising a power-shaft; a power-transmitting wheel loose on the shaft; a gear rigid with the power-shaft; a gear-train operated by said rigid gear comprising two differently-speeded elements; means rigid with the power-transmitting wheel adapted for engagement with each of said differently-speeded elements, and means for moving said elements at will into and out of such engagement.

20. A power-transmitting mechanism comprising a power-shaft; a power-transmitting wheel loose on the shaft; a gear-train operated by said gear extending to and comprising two oppositely-rotating elements; means rigid with the power-transmitting wheel adapted for engagement with each of said oppositely-rotating elements, and means for moving said elements at will into and out of such engagement.

21. A power-transmitting mechanism comprising a power-shaft; a power-transmitting wheel loose on the shaft; a gear rigid with the power-shaft, and a speed-reducing and direction-reversing gear-train intermediate said rigid gear and the power-transmitting wheel; a gear-frame for carrying the intermediate gear-train which is mounted rotatably about the power-shaft, and means for holding such frame against rotation.

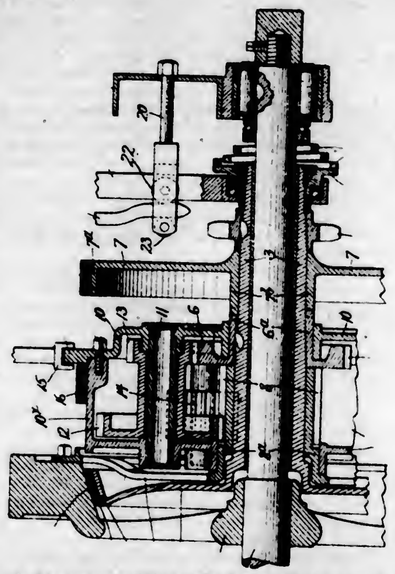
22. A power-transmitting mechanism comprising a power-shaft; a power-transmitting wheel loose on the shaft; a gear rigid with the shaft; a gear-train operated by said rigid gear comprising two oppositely-rotated and differently-speeded elements; means rigid with the power-transmitting wheel adapted for engagement with each of said oppositely-rotated and differently-speeded elements, and means for moving said elements at will into and out of such engagement.

23. A power-transmitting mechanism comprising a power-shaft; a power-transmitting wheel loose on the shaft; a gear rigid with the shaft; a gear-train operated by said rigid gear comprising two oppositely-rotated elements; means rigid with the power-transmitting wheel adapted for engagement with each of said oppositely-rotated elements; a frame by which each gear-train is carried, and means for moving the frame at will to carry said oppositely-rotated elements into and out of such engagement.

809,838. POWER-TRANSMITTING MECHANISM FOR MOTOR-VEHICLES. Rodney Starkweather, Jr., Kenosha, Wis., assignor to Thomas B. Jeffery, Kenosha, Wis. Filed Apr. 7, 1905. Serial No. 254,570.

Claim.—1. A power-transmitting mechanism comprising a power-shaft, a power-transmitting wheel loose on such shaft; a driving-gear rigid with the power-shaft; a driven gear rigid with the power-transmitting wheel; a gear-frame and a gear-train therein having an initial wheel meshing with said driving-gear and comprising two gears in different transverse planes connected in the train for opposite rotation and each adapted for meshing with the driven gear, said gear-frame being movable along the power-shaft and means for moving it back and forth.

2. A power-transmitting mechanism comprising a power-shaft, a power-transmitting wheel loose on the shaft; a driving-gear rigid with the power-shaft; a driven gear rigid with the power-transmitting wheel; a gear-frame mounted for rotation about the power-shaft; a gear-train on such frame having an initial wheel meshing with the driving-gear and comprising two gears in different transverse planes connected in the train for opposite rotation, each adapted for meshing with the driven gear; means for holding the gear-frame against rotation and means for moving it back and forth along the power-shaft.



3. A power-transmitting mechanism comprising a power-shaft, a power-wheel rigid therewith; a power-transmitting wheel loose on the power-shaft; a driving-gear rigid with the power-wheel; a driven gear rigid with the power-transmitting wheel; a planetary-gear frame mounted for rotation about the power-shaft; a gear-train on such frame having an initial wheel meshing with the driving-gear and comprising two gears in different transverse planes connected in the train for opposite rotation, each adapted for meshing with the driven gear; means for disengageably engaging the driven gear with the power-wheel; means for holding the planetary-gear frame against rotation and means for moving said frame back and forth along the shaft.

4. A power-transmitting mechanism comprising a power-shaft, a power-transmitting wheel loose or the shaft; a driving-gear rigid with the power-shaft; a driven gear rigid with the power-transmitting wheel; a planetary-gear frame journaled for rotation about the power-shaft; a gear-train on such frame comprising two gears rigid with each other situated for meshing with the driving-gear and with the driven gear respectively, said train comprising a third gear meshing with the first of said two gears in a different plane transverse to the power-shaft from the second of said gears, said planetary-gear frame being movable back and forth along the power-shaft.

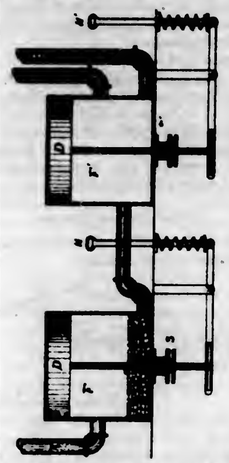
809,839. FLUID-SEALING DEVICE FOR GAS-PRODUCERS. Godfrey M. S. Taft, Montclair, N. J., assignor to Combustion Utilities Company, New York, N. Y., a Corporation of New York. Filed Aug. 17, 1905. Serial No. 274,080.

Claim.—1. A fluid-sealing device for gases comprising two chambers adapted to contain water; means for connecting the two chambers; means for raising and lowering the water-level in each chamber by displacement; and ports in said chambers affording inlet and outlet passages for the gas.

2. A fluid-sealing device consisting of two connecting-chambers having ports opening therefrom, and having displacement-plungers adapted to close one or more ports solely by the water-sealing thereof.

3. A fluid-sealing device, comprising the chambers F and F' having the gas-inlet B and the gas-outlets A and C; displacement-plungers D and D'; and connecting-passages G.

4. A fluid-sealing device comprising a chamber having a gas-inlet and two gas-outlets one or other of said outlets being at all times sealed by a water seal; a second chamber having connection with the first chamber through one of said outlets; means for simultaneously opening one of said outlets and closing the other of said outlets by water displacement.



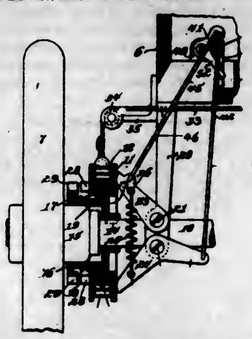
5. A fluid-sealing device comprising two chambers adapted to contain water; in the upper part of one chamber a gas-inlet in the lower part a gas-outlet and midway said inlet and outlet a second outlet connecting with the remaining chamber in its lower part; means for alternately water-sealing either of said outlets whereby one outlet is always open whenever the other outlet is closed.

809,840. WHEELBARROW. William Tasker, Biloxi, Miss. Filed Apr. 27, 1905. Serial No. 257,778.

Claim.—1. In a vehicle of the class described, a receptacle open at the rear end, spaced supporting members disposed through said receptacle and extending in advance of its closed end and rearwardly of its open end and with handles at the rear ends of the same, an axle extending transversely of said receptacle beneath the closed end thereof and provided with bearing-wheels, and U-shaped bolts for clamping around said axle and extending through said receptacle and the supporting members passing therethrough.

2. A wheelbarrow comprising a body having opposite side walls and a substantially vertical front wall, the rear end and top of the body being open, an axle secured across the under side of the bottom of the body, supporting-wheels mounted upon the axle, and a pair of bars applied to the upper face of the body and piercing the front wall thereof, said bars being extended in rear of the body and formed into handles and the other ends of the bars being projected in front of the body and forming props for engagement with the ground to support the barrow in a tilted position with its rear open end elevated.

809,841. VEHICLE-BRAKE. Bartholomew Viola, Brooklyn, N. Y. Filed Mar. 20, 1905. Serial No. 250,913.



Claim.—1. The combination with a vehicle, of a member on a wheel thereof and having engageable devices thereon, a shaft, a member shiftable relatively to said shaft, and adapted to coöperate with said engageable devices, a band-brake attached to said member to prevent its rotation when the same coöperates with said engageable devices, and levers adapted to effect the relative movement of said member.

2. The combination with a vehicle, of a member on a wheel thereof, and having engageable devices thereon, a shaft, a member shiftable relatively to said shaft and adapted to coöperate with said engageable devices, a band-brake attached to said member to prevent its rotation when the same coöperates with said engageable devices, levers adapted to effect the relative movement of said member, and means to actuate said levers.

3. The combination with a vehicle, of a member having engageable devices thereon, a shaft, a member shiftable relatively to said shaft and adapted to coöperate with said engageable devices, a band-brake attached to said member to prevent its rotation when the same coöperates with said engageable devices, means to effect the relative movement of said member, and means to control said last-mentioned means.

4. The combination with a vehicle, of a member having engageable devices thereon, a shaft, a member shiftable relatively to said shaft and adapted to coöperate with said engageable devices, a band-brake attached to said member to prevent its rotation when the same coöperates with said engageable devices, and levers adapted to press against and effect the relative movement of said member.

5. The combination with a vehicle, of a member having engageable devices thereon, a shaft, a member shiftable relatively to said shaft and adapted to coöperate with said engageable devices, a band-brake attached to said member to prevent its rotation when the same coöperates with said engageable devices, spring-actuated levers adapted to effect the relative movement of said member, means to control said levers, and means to operate said means.

6. The combination with a vehicle, of a member having engageable devices thereon, a shaft, a member, shiftable rotatively to said shaft and adapted to coöperate with said engageable devices, a band-brake attached to said member to prevent its rotation when the same coöperates with said engageable devices, spring-actuated means adapted to effect the relative movement of said member, connections to control said means, also means to operate said connection.

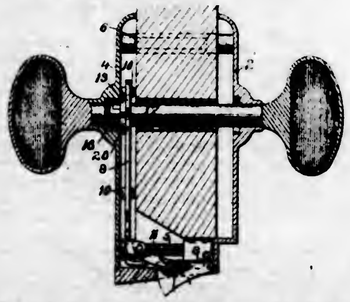
7. In a vehicle the combination with a wheel, of a member secured thereto and provided with a clutch portion an axle, a member movable thereupon and parallel to the longitudinal axis thereof and adapted to engage and operate with the first-mentioned member, a band-brake for impeding the rotation of the second member when in engagement with the first member, means to effect such engagement, and a spring to normally maintain such members disengaged.

8. In a vehicle the combination with a wheel, of a member secured thereto and provided with a clutch portion, an axle, a member movable thereupon and parallel to the longitudinal axis thereof and adapted to engage and operate with the first-mentioned member, a band-brake for impeding the rotation of the second member when in engagement with the first member, means to effect such engagement,

means to normally maintain such members disengaged, means to operate said first-mentioned means, and a connection between the vehicle and the band-brake.

9. In a vehicle the combination with a wheel, of a member secured thereto and provided with a clutch portion, an axle, a member movable thereupon and parallel to the longitudinal axis thereof and adapted to engage and operate with the first-mentioned member, a band-brake for impeding the rotation of the second member when in engagement with the first member, means to effect such engagement, means to normally maintain such members disengaged, means to operate said first-mentioned means, and a spring connection between the vehicle and the band-brake.

809,342. LOCK AND LATCH MECHANISM. HENRY G. VOIGHT, New Britain, Conn., assignor to Russell & Erwin Manufacturing Company, New Britain, Conn., a Corporation of Connecticut. Filed Mar. 27, 1905. Serial No. 252,126.



Claim.—1. In a mechanism of the character described, the combination of inner and outer side plates, an end plate, a latch-bolt carried by said end plate, an operating-slide with connections for the latch-bolt carried by the inner side plate, an inner knob having bearings in the inner side plate, an outer knob having a bearing in the outer side plate, and a shank extending from the outer knob and provided with means of connection with the operating-slide, said outer side plate being adjustable to and fro relative to said outer knob-shank.

2. In a mechanism of the character described, inner and outer side plates, an end plate, said side plates being adjustable to doors of different thicknesses, a latch-bolt, latch-operating mechanism carried by one of said side plates, a knob rotatably carried by the same side plate but having a fixed lateral position relative thereto, a second knob having a shank extending through the other side plate and rotatable therein, but capable of movement therethrough, and means of connection between said shank and said operating mechanism independent of the thickness of the door.

3. In a mechanism of the character described, the combination of two side plates adapted to the opposite sides of a door, an end plate carried by one of said side plates, a pivotally-mounted latch-bolt carried by said end plate, an operating-slide carried by the opposite side plate, an arm pivotally carried by said operating-slide and engaging said latch-bolt, and a shoulder carried by said operating-slide engaging said arm, an accessible actuating means at each side of said mechanism with connections for said operating-slide whereby said latch-bolt may be retracted independently of said slide by means of a striker-plate or retracted with said slide by said actuating means, and independently of the thickness of the door to which the mechanism is applied.

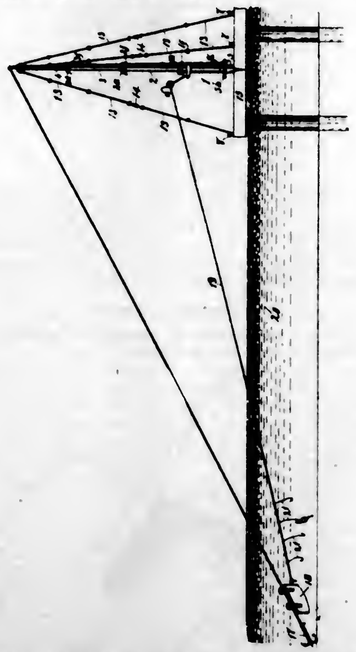
4. In a mechanism of the character described, inner and outer side plates, means for alining said plates, operating mechanism carried by the inner side plate, inner and outer knobs, a long shank projecting from the outer knob, means of connection between said knobs and said operating mechanism, clamping and supporting means for the inner end of said outer shank carried by the inner side plate, and means for releasing the same.

5. In a mechanism of the character described, an inner side plate, a knob rotatably carried thereby, a latch-bolt, operating means therefor carried by said side plate, an outer-side plate, a knob rotatably mounted but longitudinally movable in said outer side plate, and means for removably supporting the inner end of said outer knob-shank, said means being carried by said inner side plate.

6. In a mechanism of the character described, inner and outer side plates, a latch-bolt, an operating-slide therefor, a knob rotatably carried by one of said side plates, a second knob having a bearing in the other side plate and having a shank extending therethrough, clamping means carried by the first side plate for supporting the end of said shank, means for releasing said clamping means, and means of connection between said side plates whereby they may be applied to doors of different thicknesses.

7. In a mechanism of the character described, inner and outer side plates adjustable to and fro and adapted to doors of different thicknesses, an end plate carried by one of said side plates, a latch-bolt carried thereby, an operating-slide carried by one of said side plates, a knob carried by said side plate, a knob having a shank supported in but longitudinally movable through the outer side plate, means carried by the first side plate for supporting the opposite end of said shank, and means of connection between said shank and said operating-slide.

809,343. FISHING-TACKLE. BENJAMIN WALDBERG, Chicago, Ill. Filed May 6, 1905. Serial No. 259,240.



Claim.—1. In fishing-tackle, a telescopic rod, and adjustable means for holding the rod in an upright position on a dock or the like.

2. Fishing-tackle comprising a telescopic rod having several tubular sections slidably arranged one within another and provided with lock-joints, and having means for securing its lower end to a dock or the like; and adjustable means for connecting the upper end of the rod with a dock or the like.

3. Fishing-tackle comprising a rod having a screw adapted to project from its lower end, a housing for covering said screw, jointed guy-wires for holding the rod in an upright position, an anchor, a trolley-line for connecting the anchor with the top of the pole, a trolley adapted to travel on said trolley-line, a signal-bell mounted on the rod, and a fish-line carrying fish-hooks and connected with the said bell and anchor.

4. In a rod of the character described, a lock-joint comprising two concentric tubular sections slidably arranged one within the other; a collar surrounding the inner section and secured on the inner wall of the outer section adjacent to the upper end of the outer section and provided with a notch formed in its lower end, and a collar surrounding the lower end of the inner section and provided on its upper end with a hook adapted to engage the notch in the first-named collar for the purpose described.

809,344. COKE-OVEN COVER. ANDREW H. WALSTROM, Birmingham, Ala. Filed Dec. 12, 1904. Serial No. 236,573.

Claim.—1. An oven-cover having a substantial dome shape, whose radiating-surface comprises a plurality of distinct circular subsurfaces.

2. An oven-cover having a substantial dome shape, whose radiating-surface comprises a plurality of distinct circular subsurfaces, integrally formed with each other.

3. A coke-oven cover of substantial dome shape composed of a plurality of curved surfaces of different radii having their centers of curvature regularly arranged around the axial line of the oven-cover substantially as shown and described.

4. A dome-shaped oven-cover formed of a single member having a plurality of longitudinally and transversely curved circular surfaces, each surface being curved on independent radii.

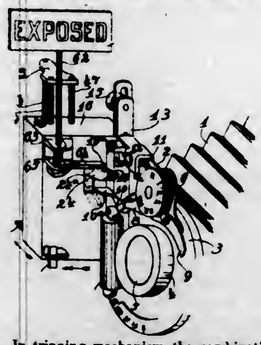
5. A dome-shaped oven-cover of an integral structure comprising a plurality of subsurfaces each formed as a circular band, each of different radii of curvature and each curved transversely on different radii, the radius of the transverse curvature of each successive surface increasing from the base of the cover toward the top thereof substantially as shown and described.

6. A dome-shaped oven-cover of an integral structure comprising a plurality of circular subsurfaces successively joining with each other, the line of juncture of each surface with the other lying in parallel horizontal planes substantially as shown and described.

7. An oven-cover of an integral structure and of substantial dome shape, comprising a plurality of surface bands each of which bands being transversely curved, the radius of transverse curvature of each successive band being different from the other, the lines of juncture between successive bands forming circles and lying in parallel horizontal planes, substantially as shown and described.

8. An oven-cover having a substantial dome shape whose radiating-surface comprises a plurality of distinct subsurfaces integrally formed with each other, the lines of juncture between the subsurfaces lying in parallel circles around a common axis.

809,345. AUTOMATIC TRIP MECHANISM. ALFRED E. WATTS, Duluth, Minn. Filed Sept. 26, 1904. Serial No. 225,944.



Claim.—1. In tripping mechanism, the combination of a casing, rock-shafts mounted in said casing, striking-fingers keyed to said rock-shafts and extending through a slot in said casing, means adapted to rock said shafts independently of each other, means adapted to temporarily prevent the rocking of said shafts, and means adapted to regulate the relative time between the rocking of one of said shafts and the rocking of the other of said shafts.

2. In tripping mechanism, the combination of a casing, a rock-shaft mounted in said casing, a striking-finger rigidly secured to said rock-shaft and extending outwardly of said casing through a slot formed therein, means for rocking said rock-shaft and means for temporarily preventing the rocking of said shaft, substantially as described.

3. In tripping mechanism, a casing, rock-shafts journaled therein, fingers rigidly secured to said rock-shafts and extending outwardly of said casing through a slot formed therein, means adapted to rock said rock-shafts, and means adapted to temporarily prevent the rocking of said shafts, substantially as described.

4. In tripping mechanism, a casing, rock-shafts journaled therein, fingers rigidly secured to said rock-shafts and extending outwardly of said casing through a slot formed therein, means adapted to rock said rock-shafts independently of each other, means adapted to temporarily prevent the rocking of one of said shafts, means adapted to temporarily prevent the rocking of the other of said shafts and also adapted to govern the first said preventing means, substantially as described.

5. In tripping mechanism, a casing, rock-shafts mounted therein, striking-fingers rigidly secured to said rock-shafts respectively, means adapted to independently rock said shafts, means adapted to temporarily prevent the rocking of one of said shafts and including a timing mechanism, means adapted to temporarily prevent the rocking of the other of said rock-shafts and also adapted to govern the means for preventing the rocking of the first said one of said rock-shafts, substantially as described.

6. In tripping mechanism, the combination of a casing, rock-shafts mounted therein, fingers rigidly secured to said rock-shafts and extending out of said casing through a slot formed therein, a signal adapted in set position to engage notches formed in said fingers and in operative position to disengage therefrom, means adapted to operate said rock-shafts independently, means including a timing device adapted to temporarily prevent the operation of one of said shafts and for holding it in set position, means including a fuse adapted to temporarily prevent the operation of the other of said rock-shafts and to hold it in set position and also adapted to govern the means for preventing the operating of the first said rock-shaft, substantially as described.

7. In tripping mechanism, the combination of a casing, spring-operated rock-shafts mounted therein, fingers secured to said rock-shafts and extending outwardly of said casing through a slot formed therein, levers keyed to said rock-shafts within said casing, pivoted levers having blocks mounted thereon adapted in operation to engage the first said levers, a pivoted lever adapted in operation to engage the foot of one of the second said levers, a cleat, a fuse adapted temporarily to secure the fifth said lever in operative position to said cleat, a spring-controlled sixth lever adapted in operation to engage the foot of the other of the second said levers, a spring adapted in operation to disengage said sixth lever from the corresponding second said lever, means adapted to temporarily suspend the operation of the last-said spring, means adapted to temporarily secure the continuance of operation of the said sixth lever against the operation of the last-said spring and including a timing device, said timing device being adapted to release said sixth lever at the expiration of a predetermined period, substantially as described.

8. In a tripping mechanism, the combination of a plural number of striking-fingers, means adapted to lower said fingers, means adapted to temporarily secure said fingers in a raised position, automatic time-regulating means adapted in set position to temporarily continue the operation of the means for securing one of said fingers in a raised position and after being released to permit the operation at the expiration of a predetermined following period of the means for lowering the last-said finger, a time-measuring device adapted to govern the operation of the means for securing the position of the other of said fingers and also adapted to govern the operation of the said time-regulating means, substantially as described.

9. In a tripping mechanism, the combination of a rock-shaft, a finger rigidly secured thereto, means adapted to rock said shaft, means adapted in operative position to prevent the operation of said shaft-rocking means, means including a fuse adapted to secure said preventive means in operative position, and means for retracting said preventive means, substantially as described.

10. In a tripping mechanism, the combination of a rock-shaft, a finger rigidly secured thereto, means adapted in operation to rock said shaft, means adapted in operation to prevent the operation of the shaft-rocking means, retracting means adapted to retract said preventive means, means including an automatic time-limiting device adapted to temporarily continue for a predetermined period the operation of said preventive means against the action of said retracting means and at the termination of said period to release said preventive means.

11. The combination with a suitable support, of fingers pivoted thereon, means adapted in set position to maintain said fingers in raised position and when released to release said fingers from such raised position, a timing device adapted to prevent the release of one of said fingers until the expiration of a predetermined period after

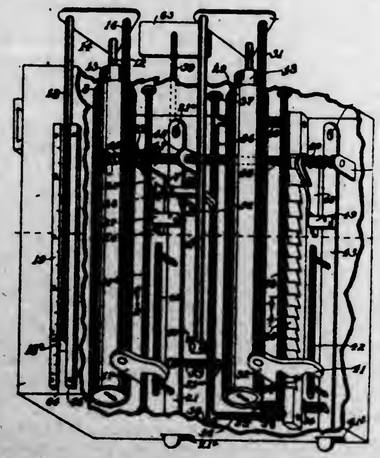
the release of the other of said fingers and upon the expiration of such period to permit the release of said one of said fingers, a timing device adapted to prevent the release of either of said fingers until the expiration of an approximately predetermined period and at the expiration of said period to permit the release of said other of said fingers.

12. The combination with a suitable support, of a striking member, means adapted to operate the same, means adapted to prevent the operation of said striking member, means adapted to retract said preventive means, and means adapted to continue the operation of said preventive means for a predetermined period against the active tendency of said retractive means and at the expiration of such period to automatically release said preventive means.

13. The combination of a support, a finger pivotally mounted thereon, a spring adapted to rock said finger, a series of levers adapted to prevent the operation of said finger and to hold it in set position, springs adapted to retract some of said levers, a cylinder, a piston therein, a piston-rod connected to said piston and extending out of said cylinder, a foot carried by said piston-rod outwardly of said cylinder and adapted to engage one of the levers of said series when said piston is raised and to hold said lever in operative position, a rack adapted to engage said foot to hold the same in raised position, a spring adapted to hold said rack in operative position, a striking member adapted to retract said rack to disengage it from said foot, a lever adapted to prevent the striking movement of said striking member, a spring adapted to retract the last-said lever, and means adapted to hold the last-said lever in operative position for an approximately predetermined period.

14. The combination with a suitable support, of a movable finger mounted thereon, means adapted to force said finger toward one end of its path of travel, means adapted in operation to hold said finger at the other end of its path of travel, means adapted to retract said holding means, and means including a timing device adapted for a predetermined period to delay the operation of said retracting means and at the expiration of such period to permit the operation of said retracting means.

809,346. AUTOMATIC TRIPPING DEVICE FOR PHOTOGRAPHIC SHUTTERS. ALFRED B. WATTS, Duluth, Minn. Filed Dec. 20, 1904. Serial No. 237,636.



Claim.—1. The combination with a suitable casing, of a lever mounted therein and extending outwardly thereof, operating means adapted to operate said lever, a second lever adapted to arrest the first said lever in set position, retracting means adapted to retract said second lever, a cylinder, a piston in said cylinder, a piston-rod connected to said piston and extending out of one end of said cylinder, lever-governing means carried by said piston adapted to arrest the second said lever in set position during a portion of the period of movement of said piston in said cylinder, and piston-governing means adapted to control the movement of said piston.

2. The combination with a suitable casing, of a lever mounted therein and extending outwardly thereof, operating means adapted to operate said lever, a second lever adapted to arrest the first said lever in set position, retracting means adapted to retract the second said lever, a cylinder, a piston in said cylinder, a piston-rod connected with said piston and extending out of one end of said cylinder, lever-governing means carried by said piston and adapted to arrest the said second lever in set position during a portion of the movement of said piston in said cylinder, governing means adapted to engage the lever-arresting means carried by said piston and to prevent lever-disengaging movement of the lever-governing means carried by said piston-rod, retracting means adapted to retract the last said lever-arresting means, and means adapted to actuate said piston.

3. The combination with a suitable support, of a lever mounted thereon, actuating means adapted to actuate said lever, a second lever adapted to arrest the first said lever in set position, retracting means adapted to retract the second said lever, a spring-actuated fluid-controlled timing device adapted for an approximately predetermined period to lock said second lever in set position, a third lever mounted on said support, means adapted to actuate said third lever, a fourth lever adapted to arrest said third lever in operative set position, means adapted to retract said fourth lever, a second spring-actuated fluid-controlled timing device adapted to arrest said fourth lever in operative set position, a fifth lever adapted in operation to arrest the first said spring-actuated fluid-controlled timing device in set position and adapted to be retracted by said third lever when the latter-said lever is actuated, the first said timing device being adapted to continue its arresting action upon said second lever for an approximately predetermined period after the retraction of said fifth lever and then to automatically release said second lever, a sixth lever, adapted to be arrested in set operation by said third lever, and means for operating said sixth lever.

4. The combination with a suitable support, of levers mounted thereon, means adapted to retract said levers respectively spring-actuated fluid-controlled timing devices engaging one of said levers and adapted to temporarily prevent the retraction of said one of said levers; other spring-actuated fluid-controlled timing devices adapted to engage another of said levers and temporarily prevent the retraction of said other of said levers and adapted to be governed by the first said devices.

5. In a tripping mechanism, the combination with a suitable support, of a series of levers mounted thereon and adapted to be held in set position, means adapted to retract said levers from said set position, a timing mechanism comprising a fluid-filled cylinder containing a spring-actuated fluid-controlled piston having a port extending therethrough, a check-valve governing the flow of said fluid through said port in one direction, means adapted to actuate said piston, a piston-rod connected to said piston, lever-engaging means carried by said rod and adapted to engage the last lever of said series and to hold it in set position for an approximately predetermined period and adapted at the expiration of said period to release said last lever, the construction being such that each of the others of said levers will be held in set position by the respectively next succeeding lever of the series and will be released upon the release of the said respectively next succeeding lever.

6. The combination with a suitable support, of a series of levers mounted thereon and adapted to be held in set position, means adapted to retract said levers from set position, a timing mechanism comprising a fluid-filled cylinder, a spring-actuated fluid-controlled piston in said cylinder and having a port extending through said piston, a check-valve adapted to prevent the flow of said fluid through said port in one direction, a piston-rod connected to said piston, lever-engaging means carried by said rod and adapted to engage the last lever of said series and to hold it in set position for an approximately predetermined period, a second series of levers mounted on said support and adapted to be held in set position, means adapted to release said levers from set position, a second timing mechanism comprising a fluid-filled cylinder, a spring-actuated fluid-controlled piston in the latter-said cylinder and having a port extending through the latter-said piston, a check-valve adapted to prevent the flow of fluid through the latter-said port in one direction, a piston-rod connected to the latter-said piston, lever-engaging means carried by the latter-said rod and adapted to engage the last lever of said second series and adapted to hold it in set position for approximately a period predetermined upon, the construction being such that each of said levers except the last of each of said series will be held in set position by the respectively next succeeding lever of the respectively corresponding series, a lever mounted on said support and adapted in set position to engage the lever-engaging means carried by the piston-rod of said second timing mechanism, to prevent the retraction of the last-said lever-engaging means,

and adapted to extend into the path of one of the levers of the first said series and to be retracted from set position by the last-referred-to lever of the first said series during the retracting movement of said lever of the first said series.

7. The combination with a suitable support, of a lever mounted thereon, means for holding said lever in operative position and comprising a fluid-filled cylinder, a piston therein provided with a port extending through said piston, a cage secured in or to said piston, a ball-valve positioned in said cage and adapted in operation to prevent a flow of fluid through said port in one direction, a piston-rod connected to said piston, a spring adapted to move said piston in the direction from which the flow of fluid through said port is prevented, and lever-engaging means carried by said piston-rod and adapted to engage said lever to hold the same in set position and adapted to disengage from said lever when said piston reaches the end of its stroke under the impulse of said spring.

809,347. ANTITOXIN FOR FATIGUE AND PROCESS OF MAKING THE SAME. WOLFGANG WEICHARDT, Berlin, Germany. Filed Jan. 18, 1904. Serial No. 189,489. (Specimens.)

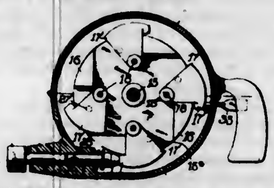
Claim.—1. The process for obtaining a substance adapted to neutralize and render inoperative the toxin arising in the human organism in cases of fatigue, which consists in producing in animals intense fatigue, obtaining from the same toxin accumulated in their organism in consequence of fatigue, by removing constituent parts containing the toxin, injecting the said toxin into other animals and subsequently abstracting suitable parts of their organism, substantially as described.

2. The process for obtaining a substance adapted to neutralize or render inoperative the toxin arising in the human body in cases of fatigue, which consists in producing in animals intense muscular fatigue, obtaining from the same toxin accumulated in their organism in consequence of fatigue, by removing organic plasm from the animal, injecting the said toxin into other animals and subsequently abstracting suitable liquid products of their organism, substantially as described.

3. The process for obtaining a substance adapted to neutralize and render inoperative the toxin arising in the human body in cases of fatigue, which consists in producing muscular fatigue in animals, bleeding the fatigued animals, taking muscular tissues from the same, maintaining it at about 37° centigrade for several hours, grinding it to pulp, pressing out superfluous liquid, filtering the plasm thus obtained, injecting it into suitable animals; and allowing it to act, then bleeding the animals thus treated and extracting the serum from the blood thus obtained, substantially as described.

4. As a new substance, a pharmaceutical preparation containing an antitoxin against the poisons arising in the human and animal organism in cases of fatigue, which preparation consists of the concentrated serum of animals treated with toxins of fatigue taken from the fatigued animals and which has the property of neutralizing or destroying these toxins, substantially as described.

809,348. POWER-HAMMER. MILTON T. WHITON, Nyack, N. Y., assignor of one-half to William F. Hutchinson, Nyack, N. Y. Filed June 3, 1904. Serial No. 210,969.



Claim.—1. A power-hammer, comprising a portable inclosing casing having a tool-holder arranged tangentially therein, a rotatable shaft journaled in the casing, a series of freely-swinging hammers hung around and carried by the shaft so as to swing within the casing opposite the tool-holder, and a clutch mechanism operated from outside the casing and acting to directly engage the individual hammers.

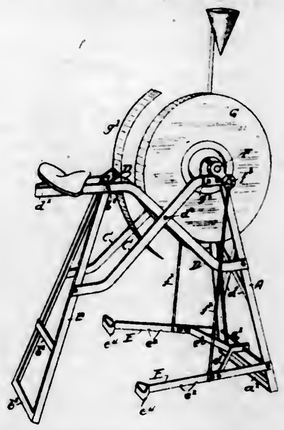
2. A power-hammer, comprising an inclosing casing having a tangentially-arranged tool-holder therein, a rotatable shaft in the casing, a disk carried by the shaft freely-swinging hammers pivoted on the disk and contained wholly within the casing, and a clutch mechanism manually controlled and operating to directly engage the hammers.

3. In a device of the kind described, the combination of the power-shaft, the disk carried thereby, the hammers pivoted on the disk, and the pins slidable through the disks to engage and stop the hammers.

4. In a device of the kind described, the combination with the power-shaft, the freely-swinging hammers supported radially around the shaft and carried thereby, the slide-disk on the shaft and the pins carried by the disk and adapted to engage the hammers as set forth.

5. The combination with the rotary disks and the hammers carried thereby, one of the disks being pierced opposite the hammers, of the spring-pins held in the perforations of the disk and arranged to engage the sides and edges of the hammers.

809,349. GRINDSTONE-FRAME. GUSTAVUS WIDEMAN, Aurora, Ill., assignor to The Richards Manufacturing Company, Aurora, Ill., a Corporation of Illinois. Filed Jan. 30, 1905. Serial No. 243,207.



Claim.—1. In a grindstone-frame, two standards; each consisting of a single bar of iron bent to form a triangle the base of which is adapted to rest on the ground, said standards arranged with their upper portions inwardly inclined, and means connecting and bracing said standards consisting of bars having their ends bolted to the standards, said bars arranged in X form and pivoted together at their intersecting points.

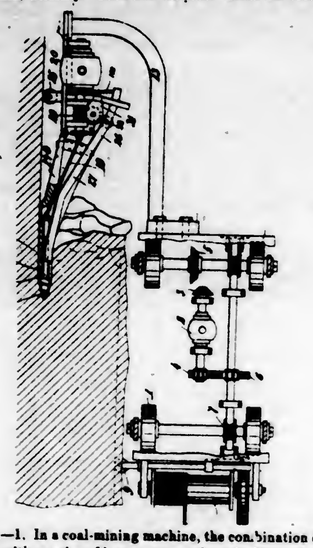
2. In a grindstone-frame, two standards each consisting of a single bar of iron bent to form a triangle the base of which is adapted to rest on the ground, and means connecting and bracing said standards consisting of bars having their ends bolted to the standards, said bars arranged in X form and pivoted together at their intersecting points, and one of said bars bent to form a seat-support substantially as described.

3. In a grindstone-frame, two standards, each consisting of a single bar of iron bent to form a triangle the base of which is adapted to rest on the ground, and means connecting and bracing said standards consisting of the bent bar D, and bars C, arranged and connected in X form, treadles pivotally connected with one of said standards, pitman-rods detachably connected with said treadles and means connecting said pitman-rods with a grindstone.

4. In a grindstone-frame, two standards, each consisting of a single bar of iron bent to form a triangle the base of which is adapted to rest on the ground, means connecting said standards consisting of bars having their ends bolted to the standards, said bars arranged in X form and pivoted together at their intersecting points, one of said bars bent to form a seat-support and extending on both sides of the frame, and the other bars bent horizontally at their upper ends to form a support on each side of the grindstone.

5. In a grindstone-frame, two triangular-shaped standards, means connecting said standards, said means consisting of metal bars bent edgewise near their ends to form horizontal portions, said portions bolted to the standards, and said bars arranged in X form and pivoted together at their points of intersection, a grindstone mounted on said frame, and means for operating said grindstone.

809,350. COAL-MINING MACHINE. CONRAD WESSELMANN, Gelsenkirchen, Germany. Filed Dec. 15, 1903. Serial No. 135,200.



Claim.—1. In a coal-mining machine, the combination of a motor-engine, with a series of borers arranged vertically one below the other and acting to drive holes parallel to the joints of the layers of coal, plates acting in the manner of wedges, the front ends of which enter the bore-holes, and means to rock said plate on a pivot at their forward ends.

2. A coal-mining machine comprising in combination a series of several borers arranged vertically one below the other, a crushing-plate and a motor-engine operating the borers and connection of said motor-engine with a cam-disk at the rear end of the crushing-plate and serving to impart oscillating movement to said crushing-plate.

3. A coal-mining machine comprising in combination a series of several levers arranged vertically one below the other and a crushing-plate acting like a wedge, and means to impart a continuous rocking movement to the rear end of said plate, a frame or scaffold, borers supported thereby, a motor-engine mounted upon the plate, a car supporting the frame or scaffold and continuously feeding the entire mechanism by the action of the motor-engine.

4. In a coal-mining machine, the combination of a series of borers arranged vertically one below the other, with a crushing-plate acting like a wedge and entering the bore-holes at its front end, means to rock the rear end of said plate, the middle section of said plate being provided with movable knife-plates, and with means for moving said knife-plates.

5. A coal-mining machine comprising in combination a series of several borers arranged vertically one below the other, and a crushing-plate having a wedge-like action, movable knife-plate on said crushing-plate, means for operating the crushing-plate, and means for operating the knife-plates.

6. In a coal-mining machine, the combination of a car with a series of rotatable drills arranged above one another, and means for simultaneously breaking the coal at the side of the drills, substantially as specified.

7. In a coal-mining machine, the combination of a car with a series of rotatable drills arranged above one another, a pivoted push-plate, and means for oscillating said plate in a lateral direction, substantially as specified.

8. In a coal-mining machine, the combination of a car with a series of rotatable drills arranged above one another, a pivoted laterally-oscillating push-plate, cutters slidable upon said plate, and means for operating said cutters, substantially as specified.

809,351. FASTENING DEVICE. EMIL WOTHE, Swinkau, Germany. Filed May 24, 1905. Serial No. 262,082.

Claim.—1. A fastening device of the character described, consisting of a head portion, comprising a plate and a plurality of resilient pins arranged in a circle and secured to said plate, each of said pins having an inward knee-shaped bend, and a base portion, comprising a plate, a socket attached to the same, and a central shank arranged in said socket and having a head, the bends of the pins being adapted to engage behind said shank-head when the head portion is in engagement with the base portion.

2. A fastening device of the character described, consisting of a head portion, comprising a plate, a plurality of resilient pins arranged in a circle and riveted to said plate, each of said pins having an inward knee-shaped bend, and a plate secured to the former plate and covering over the riveted ends of said pins, and a base portion, comprising a plate, a socket attached to the same, and a central shank arranged in said socket and having a head, the bends of the pins being adapted to engage behind said shank-head when the head portion is in engagement with the base portion.

809,352. BEDSTEAD ATTACHMENT. WILLIAM A. WEIGEL, Cumming, Ga. Filed Aug. 21, 1905. Serial No. 275,076.

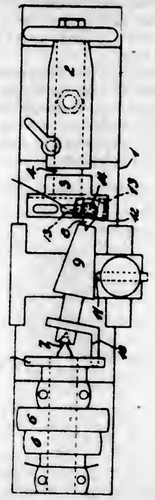
Claim.—1. An attachment for bedsteads comprising clamping members having resilient arms adapted to embrace a post of a bedstead, means for drawing said arms frictionally against the post, a rod mounted in bracket extensions of said members, a cabinet, a bar fastened thereto and bent to form lateral arms which are pivotally mounted upon said rod which is carried by said bracket extensions, as set forth.

2. An attachment for bedsteads comprising clamping members having resilient arms adapted to embrace a post of a bedstead, means for drawing said arms frictionally against the post, a rod mounted in bracket extensions of said members, a cabinet, a bar bent to form parallel bracket-arms which are apertured and adapted to receive said rod upon the bracket extensions of said members, the ends of said bar being bent at right angles to said apertured arms and fastened to said cabinet, as set forth.

3. An attachment for bedsteads comprising clamping members having resilient arms adapted to embrace a post of a bedstead, means for drawing said arms frictionally against the post, a rod mounted in bracket extensions of said members, a cabinet, a bar bent to form two parallel arms which are apertured to receive said rod upon the bracket extension of said members, the ends of said bars bent at right angles to said parallel arms and adapted to be fastened to the cabinet, portions of said bar intermediate the parallel arms thereof being inclined and terminating at their inner portions in a part of said bar which is in alinement with the angled ends thereof and fastened to said cabinet, as set forth.

4. An attachment for bedsteads comprising clamping members having resilient angled arms, the shank portions of which are apertured, a bolt passing through said apertures, a nut upon the threaded end of said bolt and adapted to bear against one of said arms, an extension of each of said members forming a bracket-support which is apertured, a rod passing through the apertures of said bracket extensions, a cabinet, and a bar fastened thereto and having portions which extend laterally and pivotally mounted upon said rod, as set forth.

809,353. LATHE ATTACHMENT. MAX C. SAGER, New Haven, Conn., assignor to Edward S. Swift, trustee, New Haven, Conn. Filed Mar. 24, 1905. Serial No. 251,725.



Claim.—1. An attachment for a lathe comprising a body portion arranged to be secured to the tail-stock spindle, and a laterally-adjustable center carried by the body of said attachment, and means for securing said center coincident with and at various points eccentric to the axis of the tail-stock spindle.

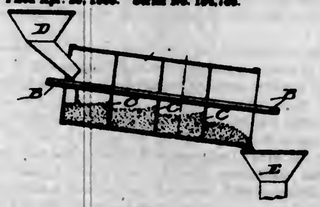
2. An attachment for a lathe comprising a body portion arranged to be secured to the tail-stock spindle, a laterally-adjustable center carried by the body of said attachment, and means for securing said center coincident with and at various points eccentric to the axis of the tail-stock spindle and at various angles relatively thereto.

3. An attachment for a lathe comprising a body portion arranged to be secured to the tail-stock spindle, a laterally-adjustable center carried by the body of said attachment, said center having a ball-like end, and means for securing said center at various points eccentric to the axis of the tail-stock.

4. An attachment for a lathe comprising a body portion arranged to be secured to the tail-stock spindle, a center, a transverse groove in said body portion intersecting said spindle said center being adjustable therein laterally relatively to the axis of said spindle, and means for clamping said center at any point in said groove.

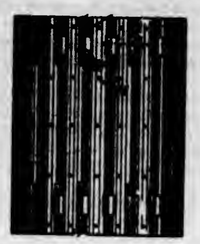
5. An attachment for a lathe, comprising a body portion arranged to be secured to the tail-stock spindle, a transverse guideway in said body portion intersecting the axis of the tail-stock, a laterally-adjustable center mounted thereon, and means for clamping said center coincident with and eccentric to the axis of said tail-stock.

809,354. METHOD OF DENSIFYING AND ELIMINATING AIR AND GAS FROM MASSES OF PULVERULENT METALLIC SALTS AND OXIDS. BAYER O. BARTLETT and WILLIAM F. GORDON, Joplin, Mo. Filed Apr. 29, 1903. Serial No. 154,726.



Claim.—The method of densifying and eliminating air and gas from dry masses of pulverulent metallic salts and oxids, which consists in treating a mass of such pulverulent material in a rotating receptacle to cause the mass as a whole to revolve in the receptacle and its component particles to constantly shift their relative positions as described.

809,355. CENTRIFUGAL CREAM-SEPARATOR. EDGAR W. BROCKALL, Rochester, N. Y. Filed May 23, 1905. Serial No. 261,699.

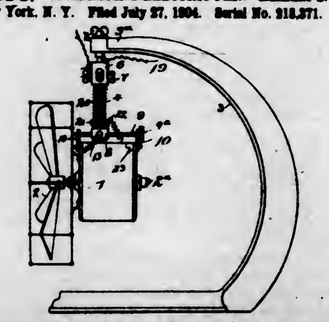


Claim.—1. In a centrifugal cream-separator, the combination with a rotary bowl, of a series of vertical, cream-collecting plates that intersect the radial lines of the bowl adjacent to its wall, leaving space for milk between said plates and said wall, said plates having passages through which the milk can pass to the wall of the bowl; and division-blades adjacent to said cream-collecting plates, adapted to receive the cream from both sides of said plates and to conduct it inwardly.

2. In a centrifugal cream-separator, the combination with a rotary bowl, of a series of division-blades having angular portions that intersect the radial lines of the bowl adjacent to its wall and leave space for milk between such portions and the wall of the bowl, said blades having passages for the milk to pass to the wall of the bowl from the spaces between said blades, each of said angular portions of said blades approaching another blade whereby cream is delivered from both of its sides to such other blade to be conducted inwardly thereby.

3. In a centrifugal cream-separator, the combination with a rotary bowl, of a series of vertical, cream-collecting plates that intersect the radial lines of the bowl and form a series of vertical compartments for milk between them and the wall, said plates having passages through which milk can pass to said vertical channels; and division-blades adjacent to said cream-collecting plates, adapted to receive the cream from both sides of said plates and to conduct it inwardly.

809,356. OSCILLATING ELECTRIC FAN. HERBERT S. BROWN, New York, N. Y. Filed July 27, 1904. Serial No. 218,271.



Claim.—1. The combination, with a fan having its axis placed at an angle to the vertical and arranged to deliver a stream of air in the general direction of said axis, of an electric motor therefor and a suspending device having means for producing torsional reaction to the movement of the fan about the suspending device as a pivot, whereby variations in the current supplied to the motor serve to maintain oscillation of the fan, substantially as described.

2. The combination, with an electric motor-driven fan having its axis placed at an angle to the vertical and arranged to deliver a stream of air in the general direction of said axis, of a suspending

device having means for producing torsional reaction to the movement of the fan about the suspending device as a pivot, and means for supplying current to the motor, whereby variations in the current serve to maintain oscillation of the fan, substantially as described.

3. The combination, with an electric motor-driven fan having its axis placed at an angle to the vertical and arranged to deliver a stream of air in the general direction of said axis, of a suspending device having means for producing torsional reaction to the movement of the fan about the suspending device as a pivot, the axis of the fan and of the suspending device being in one vertical plane, and means for supplying current to the motor, whereby variations in the current serve to maintain oscillation of the fan, substantially as described.

4. The combination of an electric fan, having a motor, with a hanger above the same, a flexible connection between the hanger and the fan, means for adjusting the operative length of said connection between the fan and hanger, and means to convey electrical current to the motor from a source of electrical energy, substantially as described.

5. The combination of an electric fan having a motor, with a hanger above the same, terminals connected with said hanger for connection with the line-wires, a flexible support for the fan depending from the hanger, conductors connecting said terminals with the motor, and means for adjusting the fan laterally with respect to said support, substantially as described.

6. The combination of an electric fan, a horizontally-disposed rod having a block for adjustment along the fan, a hanger above the fan, and a flexible connection between the hanger and the block, substantially as described.

7. The combination of an electric fan, a horizontally-disposed rod having a block for adjustment along the fan, a hanger above the fan, a flexible connection between the hanger and the block, and means for adjusting the operative length of the support between the hanger and the fan, substantially as described.

8. The combination of an electric fan with a block provided with a shaft, a flexible support connecting said shaft with the fan, and means for supporting said block, substantially as described.

9. The combination of an electric fan with a flexible support for the fan, means for sustaining said support, and a shaft connected with said support for regulating the operative length of the support, substantially as described.

10. The combination of an electric fan, with a block having a shaft, a flexible support connecting said shaft with the fan, and a conductor in circuit with the fan-motor and connected with said shaft, substantially as described.

11. The combination of an electric fan, a hanger, a block connected therewith, a shaft carried by the block, a flexible support connecting the shaft with the fan, a conductor connected with said shaft and in circuit with the fan-motor, a contact in circuit with said shaft for connection with a line-wire, and another conductor connected with the terminal of the motor for connection with the line-wire, substantially as described.

12. The combination of an electric fan, with a block, a flexible support connecting the block with the fan, a conductor coiled around said flexible support and in circuit with the fan-motor, and another conductor in circuit with the fan-motor, substantially as described.

13. The combination of an electric fan with a block, a flexible support connecting the block with the fan, a conductor coiled around said flexible support and in circuit with the fan-motor, another conductor in circuit with the fan-motor, and means for holding the support and coiled conductor under opposing twisting strains, substantially as described.

14. The combination of an electric fan, with a pair of blocks, one of which is connected with the fan, a hanger for the other block, a flexible support connecting said blocks, a coiled conductor surrounding said flexible support and connected with said blocks and in circuit with the fan-motor, and another conductor in circuit with the fan-motor, substantially as described.

15. A support for an oscillating fan comprising a pair of blocks, a flexible support connecting said blocks, and a coiled conductor connected with said blocks and inclosing said support, substantially as described.

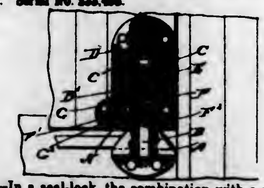
16. A support for an oscillating fan comprising a pair of blocks, a flexible support connecting said blocks, a coiled conductor connected with said blocks and inclosing said support, and means for adjusting said coiled conductor and one of the blocks with respect to each other, substantially as described.

17. A support for an oscillating electric fan, comprising a pair of blocks, a shaft carried by one block, a flexible support connecting said shaft with the other block, and a coiled wire connected with said blocks and surrounding said support, substantially as described.

18. A support for an oscillating electric fan, comprising a pair of blocks, a shaft carried by one block, a flexible support connecting said shaft with the other block, a coiled spring connected with said blocks and surrounding said support, and a conductor connected with said shaft and with a contact carried by the opposite block, substantially as described.

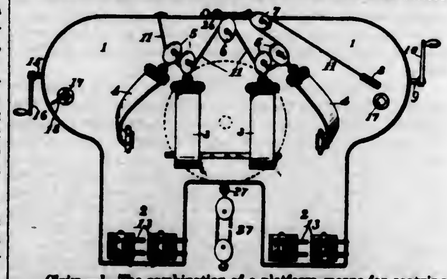
19. A support for an electric fan comprising a pair of blocks, a shaft carried by one block, a flexible support connecting said shaft to the other block, a conductor connected with said shaft and leading to the other block, a coiled conductor surrounding said support, and contacts carried by said blocks for connection with the coiled conductor, substantially as described.

809,357. **SEAL-LOCK.** PHILIP S. CLAUSEN, Aurora, Ill. Filed Nov. 19, 1904. Serial No. 233,469.



Claim.—In a seal-lock, the combination with a plate provided with guides and housing, said guides and housing being apertured, a dog pivoted in the housing, a bolt sliding between the guides and provided with a transverse aperture, a seal adapted to be passed through the apertured guides and bolt, said seal having an arrow-head at one end which is adapted to be engaged by the pivoted dog, the opposite end of the seal being provided with a flat head, the seal being reduced adjacent said flat head, for the purpose described.

809,358. **VETERINARY SURGEON'S TABLE.** LEONARD L. CONKEY, Grand Rapids, Mich. Filed Feb. 1, 1905. Serial No. 243,630.



Claim.—1. The combination of a platform, means for securing an animal upon the same, a support for the platform, and a double-jointed hinge connecting the platform and support.

2. The combination of a platform, means for securing an animal upon the same, a support for the platform, means for rotating the support about a vertical axis, and a double-jointed hinge connecting the platform and support.

3. The combination of a platform, means for securing an animal upon the same, a support for the platform, a double-jointed hinge connecting the platform and support, and a hoisting-tackle adapted to be attached to either side of the platform to elevate the same.

4. The combination of a platform, means for supporting the platform in a vertical position, means for supporting the same in a horizontal position, straps to engage the body of an animal and attached to the platform at one end, pulleys on the free ends of the straps, a cord engaging the pulleys, means for adjusting the cord, bands adapted to be attached to the legs of an animal, cords attached to the bands, and means for adjusting the said cords.

5. The combination of a platform, means for supporting the same in either a vertical, or an inclined position, means for supporting the platform in a horizontal position, straps attached at one end to the platform, pulleys on the free ends of the straps, pulleys on the platform, a cord attached to the platform and successively engaging said pulleys, a shaft journaled on the platform on which shaft the cord is wound, a crank on the shaft, a pawl and ratchet to hold the shaft, and means for securing the legs of the animal to the platform.

6. The combination of a platform, means for adjustably supporting the platform, straps attached to the platform at one end, pulleys attached to the free ends of the straps, pulleys attached to the platform, a cord attached to the platform at one end and successively engaging the pulleys, a shaft on which the cord is wound, means for rotating and holding the shaft, bands to attach to the legs of the animal, cords attached to the bands, a shaft on which the cords are wound, and means for rotating and holding the shaft.

7. The combination of a platform, a support for the platform and rotative on a vertical axis, double-jointed hinges connecting the platform and the support, four straps attached at one end to the platform, a pulley on each free end of each strap, two pulleys attached to the edge of the platform, a pulley in an opening in the platform, a cord attached to the platform at one end and thence extending through two of the strap-pulleys, thence through a platform-pulley, thence through the other two strap-pulleys, thence through the other platform-pulley, thence over the pulley in the opening, a shaft journaled on the platform, around which shaft the other end of the cord is wound, a crank and ratchet on the shaft, and a pawl engaging the ratchet.

8. The combination of a platform, means for attaching an animal to said platform, a support for said platform rotative on a vertical axis, an upper hinge member attached to the platform, a lower hinge member attached to the support, and a middle hinge member extending wholly across the top of the support and pivoted at its respective ends to the other hinge members.

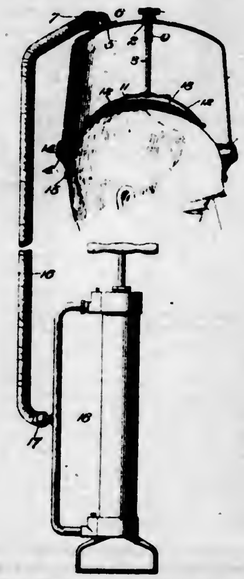
9. The combination of a platform, means for adjustably supporting the same, straps to engage the body of an animal and attached to the platform at one end, a cord connected to the free end of said straps, a shaft on which the cord is wound, means for rotating and holding the shaft, bands to surround the legs of an animal, cords attached to the bands, a shaft on which the cords are wound, and means for rotating and holding the said shaft.

10. The combination of a bed having a circular track, rolls traversing the track, a rotative circular track above the rolls, a support mounted on the rotative track, a spider and center bolt to hold the support in place, transverse beams on the support, double-jointed hinges attached to the beams, a platform attached to the hinges, and means for securing an animal upon the platform.

809,359. **DISPLAY-HANGER.** GRANT D. DIAL, Chicago, Ill. Filed Dec. 17, 1904. Serial No. 237,262.

Claim.—As a new article, a bar having means for suspension from a stationary structure and provided with a plurality of spaced apertures, and flexible suspension members of varying lengths and connected at their ends in said apertures and hanging therefrom in loops of graduated lengths.

809,360. **APPARATUS FOR PROMOTING THE GROWTH OF HAIR.** NAPOLEON W. DIBLE, Kansas City, Mo. Filed Oct. 4, 1904. Serial No. 227,104.



Claim.—1. An air-tight cap, an elastic band secured to the lower margin of the same, a support within the cap to rest upon the patient's head, means whereby the support is free to move toward or from the crown of the cap, and means whereby said support may be secured at the desired distance from the crown of the cap.

2. An air-tight cap, an elastic band secured to the lower margin of the same, a support within the cap to rest upon the patient's head, and a rod vertically adjustable through the crown of the cap and attached at its lower end to the support.

3. An air-tight cap having a threaded hole in its crown, an elastic band secured to the lower margin of said cap, a support within the cap to rest upon the patient's head, and a rod attached at its lower end to said support and capable of sliding through the threaded hole of the cap, and provided with a threaded portion for engagement at times with said threaded hole.

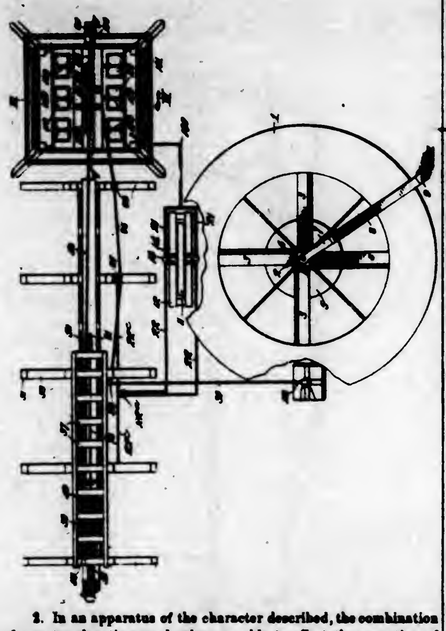
4. An air-tight cap having a threaded hole in its crown, an elastic band secured to the lower margin of said cap, a support within the cap to rest upon the patient's head, a rod attached at its lower end to said support and capable of sliding through the threaded hole of the cap and provided with a threaded portion for engagement at times with said threaded hole, and a handle secured to the upper end of the rod externally of the cap.

5. An air-tight cap, an elastic band secured to the lower margin of the same, and a support within the cap to rest upon the patient's head, the same comprising an inverted cup provided with openings, and a foraminous bottom bridging the lower side of said openings.

6. An air-tight cap, an elastic band secured to the lower margin of the same, a support within the cap to rest upon the patient's head, the same comprising an inverted cup provided with openings and a foraminous bottom bridging the lower side of said openings, and means for creating a vacuum in said cap.

809,361. **WATER ELEVATING AND STORAGE APPARATUS.** WILLIAM W. DOUGLASS, Kansas City, Mo. Filed June 9, 1904. Serial No. 211,893.

Claim.—1. In an apparatus of the character described, the combination of a water-elevating mechanism, a cable to effect the operation of said mechanism, a suitable framework, a stationary drum therein to which is rigidly secured said cable, and a drum movable toward and from the stationary drum and engaged by a loop in said cable.



2. In an apparatus of the character described, the combination of a water-elevating mechanism, a cable to effect the operation of said mechanism, a suitable framework, a stationary drum therein to which is rigidly secured said cable, a drum movable toward and from the stationary drum and engaged by a loop in said cable, and means for effecting the travel of said movable drum from the stationary drum.

3. In an apparatus of the character described, the combination of a water-elevating mechanism, a cable to effect the operation of said mechanism, a suitable framework, a stationary drum therein to which is rigidly secured said cable, a drum movable toward and from the stationary drum and engaged by a loop in said cable, means for effecting the travel of said movable drum from the stationary drum, and means for moving the movable drum toward the stationary drum.

4. In an apparatus of the character described, the combination of a water-elevating mechanism, a cable to effect the operation of said mechanism, a suitable framework, a stationary drum therein to which is rigidly secured said cable, a drum movable toward and from the stationary drum and engaged by a loop in said cable, and an expansive frame connected to the movable drum and adapted when expanding to move said drum away from the stationary drum.

5. In an apparatus of the character described, the combination of a water-elevating mechanism, a cable to effect the operation of said mechanism, a suitable framework, a stationary drum to which is rigidly secured said cable, a drum movable toward and from the stationary drum and engaged by a loop in said cable, an expansive frame connected to the movable drum and adapted when expanding to move said drum away from the stationary drum, and means for yieldingly impelling the movable drum toward the stationary drum after the expansion of said frame has occurred.

6. In an apparatus of the character described, the combination of a water-elevating mechanism, a cable to effect the operation of said mechanism, a suitable framework, a stationary drum to which is rigidly secured said cable, a drum movable toward and from the stationary drum and engaged by a loop in said cable, an expansive frame having one end fixed and the other movable, and a suitably-guided cable connected to the movable end of the expansive frame and to said movable drum.

7. In an apparatus of the character described, the combination of a water-elevating mechanism, a cable to effect the operation of said mechanism, a suitable framework, a stationary drum to which is rigidly secured said cable, a drum movable toward and from the stationary drum and engaged by a loop in said cable, an expansive frame having one end fixed and the other movable, a suitably-guided cable connected to the movable end of the expansive frame and to said movable drum, one or more hydraulic jacks for effecting the expansion of said frame, and means for discharging the water from said jack or jacks to permit said frame to contract.

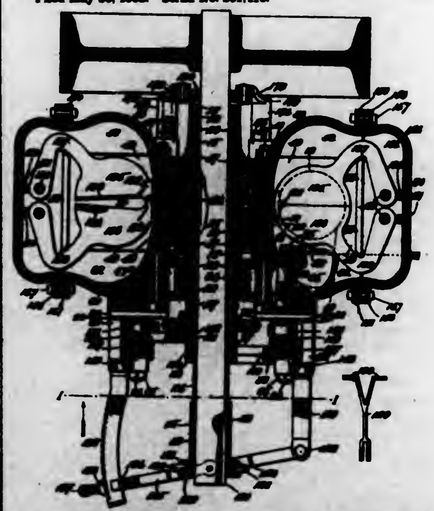
8. In an apparatus of the character described, the combination of a water-elevating mechanism, a framework, a stationary frame therein, a vertically-movable frame therein, a lazy-tongs frame secured at one end to the framework, and arranged between the superposed movable and stationary frames, a stationary drum in said framework, a drum to travel toward and from said stationary drum, a cable secured at one end to the stationary drum and looped around the same and the movable drum and extending from the stationary drum and connected at its opposite end to the water-elevating mechanism to operate the same, means for drawing the movable drum yieldingly toward the stationary drum, a suitably-guided cable connecting the movable drum and the free end of the lazy-tongs frame, one or more valve-controlled hydraulic rams supporting the movable frame, a force-pump having a check-valve-controlled pipe connection with said ram or rams, a vertically-slidable weight on the framework, a disk connected to open and close the valve of each ram, a link connecting the disk and slidable weight, a spring-actuated bolt to lock the disk against back rotation when the weight is raised, means operated by the water-elevating mechanism to raise said weight and open the ram-valve when the vertically-movable frame is elevated, and means also actuated by the operation of the water-elevating mechanism for unlocking the bolt from said disk to permit the weight to descend.

809,862. **PROCESS OF MAKING DIALKYL-BARBITURIC ACIDS.** MAX BISCHLEBEN, Elberfeld, Germany, assignor to Farbenfabriken of Elberfeld Co., New York, N. Y., a Corporation of New York. Filed Oct. 16, 1905. Serial No. 283,017.

Claim.—1. The process for the production of dialkyl-barbituric acids having the above-given general formula, which process consists in heating 2-thio-4-imino-5-dialkyl-6-oxypyrimidins with acids, substantially as hereinbefore described.

2. The process for the production of diethyl-barbituric acid, which process consists in heating 2-thio-4-imino-5-diethyl-6-oxypyrimidin with acids, substantially as hereinbefore described.

809,863. **ROTARY ENGINE.** ALBERT O. ENGLUND, Wayne, Kans. Filed May 20, 1905. Serial No. 261,416.



Claim.—1. A rotary engine, comprising a cylinder having a circular chamber, a shaft centrally of and surrounded by said chamber,

a piston rigid with the shaft and partitioning the chamber, a gate partitioning the chamber, valve-controlled inlet and exhaust ports communicating with the chamber at opposite sides of the gate, means for opening the inlet-port valve to admit steam to the chamber between the piston and said gate, means to close the exhaust-port valve as the piston passes the point of communication of the exhaust-port with the chamber, means for opening the gate to permit the piston to pass, and means to close the inlet-port valve at a predetermined time.

2. A rotary engine, comprising a cylinder having a circular chamber, a shaft centrally of and surrounded by said chamber, a piston rigid with the shaft and partitioning the chamber, a gate partitioning the chamber, valve-controlled inlet and exhaust ports communicating with the chamber at opposite sides of the gate, means for opening the inlet-port valve to admit steam to the chamber between the piston and said gate, means to close the exhaust-port valve as the piston passes the point of communication of the exhaust-port with the chamber, means for opening the gate to permit the piston to pass, means to close the inlet-port valve at a predetermined time, means to reopen the exhaust-port valve after the piston passes its point of communication with the said chamber, and means to reclose the gate after the piston passes it.

3. A rotary engine, comprising a cylinder having a circular chamber, a shaft centrally of and surrounded by said chamber, a piston rigid with the shaft and partitioning the chamber, diametrically opposite gates, valve-controlled inlet-ports communicating with the chamber at diametrically opposite points and at opposite sides of the plane of said gates, and valve-controlled exhaust-ports communicating with the chamber at diametrically opposite points, and at opposite sides of the plane of the gates.

4. A rotary engine, comprising a cylinder having a circular chamber, a shaft centrally of and surrounded by said chamber, a piston rigid with the shaft and partitioning the chamber, diametrically opposite gates, valve-controlled inlet-ports communicating with the chamber at diametrically opposite points and at opposite sides of the plane of said gates, valve-controlled exhaust-ports communicating with the chamber at diametrically opposite points, and at opposite sides of the plane of the gates, means for alternately opening the inlet-port valves, means for closing said valves, means for alternately opening the exhaust-port valves, means for closing said valves, means for alternately opening the gates, and means for closing said gates.

5. A rotary engine, comprising a cylinder having a circular chamber, a shaft centrally of and surrounded by said chamber, a piston rigid with the shaft and partitioning the chamber, diametrically opposite gates, valve-controlled inlet-ports communicating with the chamber at diametrically opposite points and at opposite sides of the plane of said gates, valve-controlled exhaust-ports communicating with the chamber at diametrically opposite points and at opposite sides of the plane of the gates, means for alternately closing the inlet-port valves, springs for opening said valves, means for alternately closing the exhaust-port valves, springs for opening said valves, means for alternately opening the gates, and means for closing said gates.

6. A rotary engine, comprising a cylinder having a circular chamber, a shaft centrally of and surrounded by said chamber, a piston rigid with the shaft and partitioning the chamber, diametrically opposite gates, valve-controlled inlet-ports communicating with the chamber at diametrically opposite points and at opposite sides of the plane of said gates, valve-controlled exhaust-ports communicating with the chamber at diametrically opposite points and at opposite sides of the plane of the gates, piston-actuated means for alternately closing the inlet-port valves, means for opening said valves, piston-actuated means for alternately closing the exhaust-port valves, means for opening said valves, piston-actuated means for opening the gates, and means for closing said gates.

7. A rotary engine, comprising a cylinder having a circular chamber, a shaft centrally of and surrounded by said chamber, a piston rigid with the shaft and partitioning the chamber, diametrically opposite gates, valve-controlled inlet-ports communicating with the chamber at diametrically opposite points and at opposite sides of the plane of said gates, valve-controlled exhaust-ports communicating with the chamber at diametrically opposite points and at opposite sides of the plane of the gates, piston-actuated means for alternately closing the inlet-port valves, springs for opening said valves, piston-actuated means for alternately closing the exhaust-port valves, springs for opening said valves, means for alternately opening the gates, and means for closing said gates.

8. A rotary engine, comprising a cylinder having a circular chamber, a shaft centrally of and surrounded by said chamber, a piston rigid with the shaft and partitioning the chamber, diametrically opposite gates, valve-controlled inlet-ports communicating with the chamber at diametrically opposite points and at opposite sides of the plane of the gates, valve-controlled exhaust-ports communicating with the chamber at diametrically opposite points and at opposite sides of the plane of the gates, independent means holding the valves yieldingly open, a cam rotatable with the shaft, means caused by said cam to alternately close the inlet-port valves, a second cam rotatable with the shaft, means caused by said cam to alternately close the exhaust-port valves, means for alternately opening the gates, and means for closing said gates.

9. A rotary engine, comprising a cylinder having a circular chamber, a shaft centrally of and surrounded by said chamber, a piston rigid with the shaft and partitioning the chamber, a valve-controlled exhaust-port communicating with the chamber, an adjustable cam journaled on the shaft, a sliding sleeve mounted on the sleeve a lever suitably supported and connected to slide the sliding sleeve, means whereby movement of the sliding sleeve shall rotate the adjustable cam, means for locking the cam at the desired point of adjustment, and means whereby said cam under the revolution of the shaft shall operate said valve.

10. In a rotary engine, a cylinder, comprising two members secured together and provided with mating circular grooves conjointly forming a circular passage, a shaft journaled in the cylinder centrally of the circular chamber, a disk secured rigidly on the shaft between the members of and within the cylinder, and provided with a peripheral recess, a bolt secured in said disk and having its head snugly engaging said recess to form a part of the disk, means to prevent said bolt from turning, a piston secured rigidly to said bolt and projecting outwardly from said head and partitioning the cylinder-chamber, and friction-rings carried by said piston and engaging the walls of said chamber.

11. In a rotary engine, a cylinder having a circular chamber and an intersecting shallow gate-passage, and a gate comprising a pair of members suitably pivoted and adapted to partition said chamber by swinging inwardly until they meet and to leave said chamber unobstructed by swinging outwardly; each member of the gate being provided at its inner or free end with an extension of half its thickness adapted to overlap each other, and one of the members having a groove in its inner edge and the other a tongue to engage said groove when the members are swung together to conjointly partition the cylinder-chamber.

12. A rotary engine, comprising a cylinder having a circular chamber, a shaft centrally of and surrounded by said chamber, a piston rigid with the shaft and partitioning the chamber, diametrically opposite gates, valve-controlled inlet-ports communicating with the chamber at diametrically opposite points and at opposite sides of the plane of the gates, valve-controlled exhaust-ports communicating with the chamber at diametrically opposite points and at opposite sides of the plane of the gates, independent means holding the valves yieldingly closed, a cam rotatable with the shaft, means caused by said cam to alternately open the inlet-port valves, a second cam rotatable with the shaft, means caused by said cam to alternately open the exhaust-port valves, a third cam rotatable with the shaft, means actuated by said cam to alternately open the gates, and means for closing said gates.

13. In a rotary engine, a circular chamber, a shaft centrally of and surrounded by said chamber, a piston rigid with the shaft and partitioning the chamber, diametrically opposite gates, inlet-ports communicating with the chamber at diametrically opposite points and at opposite sides of the plane of said gates, exhaust-ports communicating with said chamber at diametrically opposite points and at opposite sides of the plane of said gates, rotary valves for all of said ports, helical springs to hold said valves normally open, means for alternately closing the inlet-ports, means for alternately closing the exhaust-ports, means for alternately opening the gates, and means for alternately closing them.

14. In a rotary engine, a circular chamber, a shaft centrally of and surrounded by said chamber, a piston rigid with the shaft and partitioning the chamber, diametrically opposite gates, inlet-ports communicating with the chamber at diametrically opposite points and at opposite sides of the plane of said gates, exhaust-ports communicating with said chamber at diametrically opposite points and at opposite sides of the plane of said gates, conical rotary valves, yielding means to resist endwise movement of said valves, means to overcome such resistance and adjust and secure said valves in their new positions to compensate for wear and prevent leakage of steam around them, means for alternately closing the inlet-port valves, means for alternately closing the exhaust-port valves, means for alternately opening the gates, and means for alternately closing them

15. In a rotary engine, a cylinder having a circular chamber, a shaft centrally of and surrounded by said chamber, a piston rigid with the shaft and partitioning the chamber, a valve-controlled exhaust-port communicating with the chamber, an adjustable cam journaled on the shaft, a sliding sleeve mounted on the shaft and provided with a spiral slot, a rotatable sleeve on the shaft and secured to the adjustable cam and provided with a pin engaging the spiral slot of the sliding sleeve, a lever suitably supported and connected to slide the sliding sleeve, means for locking the adjustable cam at the desired point, and means whereby said cam under the revolution of the shaft shall operate said valve.

809,364. BRIDLE-BIT. CHARLES H. FALLS, Clarksville, Iowa. Filed July 20, 1905. Serial No. 271,757.

Claim.—1. A bit, having integral snaffles terminating in eyes, split plugs engaging the hollow ends of said bit, oscillating rein-loops connected to eyes in said plugs, each of said plugs having a saddle with a seat to be engaged by said rein-loops, as set forth.

2. A bit, having integral snaffles with eyes in the ends thereof, split plugs having eyes and integral saddles adapted to seat, respectively, in the hollow ends of said bit and recesses in the ends of the bit, and rein-loops engaging said eyes formed in said plugs, and adapted to seat in said saddles, as set forth.

3. A bit, having integral snaffles with eyes in the ends thereof, split plugs, having their outer faces tapering and adapted to frictionally engage the inclined walls in the ends of said bit, an integral saddle upon each plug, each saddle having a concaved part, forming a seat, the edge of said saddle adapted to engage in a recess formed at right angles in the bit to the length thereof, rein-loops engaging elongated eyes formed in said plugs, and a jaw-strap connecting said loops, as set forth.

4. A bit, having integral snaffles with eyes in the ends thereof, split plugs, having their outer faces tapering and adapted to frictionally engage the inclined walls in the ends of said bit, an integral saddle upon each plug, each saddle having a concaved part, forming a seat, the inner edge of each saddle having its opposite walls inclined and designed to engage the tapering walls of recesses in the ends of the bit, and rein-loops engaging eyes formed in said plugs, as set forth.

5. A bit, having integral snaffles and eyes at the ends thereof, split plugs engaging in the ends of said bit, and provided each with a saddle held in a recess formed at right angles to the length of the bit, rein-loops engaging eyes in said plugs and having cross-bars to which a jaw-strap is adapted to be fastened, as set forth.

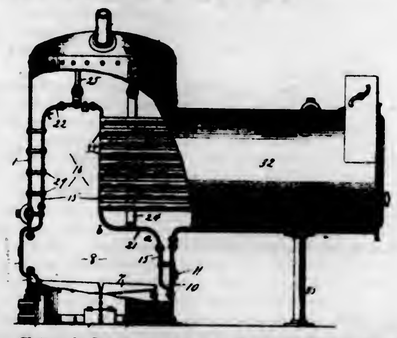
809,365. DENTAL TOOL. ADAM W. PHILPHANN, Chicago, Ill. Filed Apr. 20, 1905. Serial No. 256,610.

Claim.—1. In a dental tool, in combination with the exterior element or barrel, a plunger reciprocating in the barrel and having jaws which are operated by such reciprocation, the plunger being exteriorly threaded at a portion of its length, and a nut engaging such threaded portion of the plunger and stopped on the barrel against movement longitudinally therein in one direction.

2. In a dental tool, in combination with the exterior element or barrel, a plunger reciprocating in the barrel, and having jaws protruding therefrom which are operated by such reciprocation; a spring reacting between the plunger and the barrel for yieldingly resisting the longitudinal movement of the plunger in one direction and retracting it in the opposite direction; an element which is stopped on the barrel against movement longitudinally thereon in the opposite direction from that in which the spring reacts against the plunger, said stopped element having threaded engagement with the plunger.

3. In a dental tool, in combination with the exterior element or barrel, a plunger reciprocating in the barrel having jaws which are operated by such reciprocation; a spring reacting between the plunger and the barrel for yieldingly resisting the forward longitudinal movement of the plunger and retracting it rearward, the plunger being protruded from the barrel at the upper or rear end, and exteriorly threaded at such protruded portion, and a nut adjustable thereon for stopping against the upper end of the barrel.

809,366. STEAM-GENERATOR. DAVID FITZSIMMONS, Oswego, N. Y. Filed May 27, 1905. Serial No. 262,568.



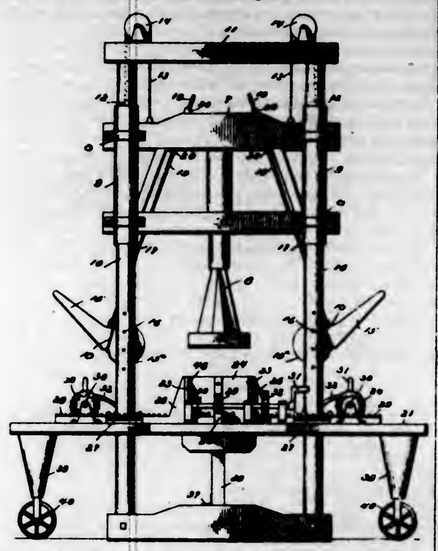
Claim.—1. In a steam-generator, the combination with a vertical cylindrical shell inclosing an ash-pit below, of an inner shell having a cylindrical lower portion forming a fire-box and a semicylindrical upper portion forming a combustion-chamber, said inner shell being arranged within the cylindrical shell and having its lower margin connected thereto to form a water-leg around the fire-box, a grate above the ash-pit, a horizontal cylindrical shell extending rearwardly from the vertical shell, tubes in the horizontal shell secured to the rear wall of the combustion-chamber, and two braces supporting the inner shell in the outer shell, one brace being connected to the front higher portion of the inner shell and one brace being connected to the rear lower portion of the inner shell.

2. In a steam-generator, an outer, vertical cylindrical shell, an annular flanged, supporting-casting fitted to the foot of said shell, an inner shell or crown-sheet arranged within the outer shell and riveted to said outer shell around its lower margin, said inner shell being formed with a cylindrical lower portion, a semicylindrical upper portion arranged above the front of the lower portion and a straight vertical wall forming the rear face of said upper portion, said lower portion forming the fire-box and having a rear half-dome over the fire-box, said upper portion forming a combustion-chamber and having a front half-dome over the combustion-chamber, the curves between the fire-box wall, and the rear half-dome, between said rear half-dome and said vertical wall, and between the combustion-chamber front wall and the front half-dome being curves in the arcs of large circles, and a horizontal, cylindrical shell containing tubes extending from the vertical shell.

3. In a steam-generator, an outer cylindrical shell, vertically arranged, an inner shell inclosed within the outer and having its lower margin secured thereto, the inner shell having a lower cylindrical portion forming a fire-box, and an upper semicylindrical portion above the front of the fire-box forming a combustion-chamber, the top of said upper portion, and the top of said lower portion behind the combustion-chamber being in the form of half-domes, the bends in said inner shell being arcs of large circles, a single brace between each of said half-domes and the outer shell, and a horizontally-arranged cylindrical shell rearwardly extending from the vertical shell and containing the fire-tubes, substantially as described and shown.

809,367. BLOCK-MOLDING MACHINE. HARVEY P. GATES, Remington, Ind. Filed June 22, 1905. Serial No. 266,402.

Claim.—1. In a block-molding machine, the combination with a table mounted on wheels and having a mold-box, of a pressure-frame having a plunger over the box, and having supporting-sills under the table and movable up and down with respect thereto, to support the frame on the table or on the ground.



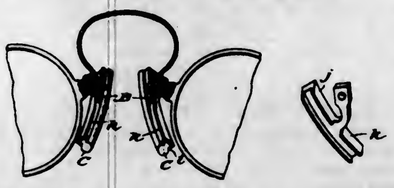
2. In a block-molding machine, the combination with a table and mold thereon, of tubular standards extending above the table, sleeves slidable up and down on the standards, and a plunger-frame secured to the sleeves and having counterbalance-weights connected thereto and located inside the standards.

3. The combination with a table and pallet, of a mold-box thereon having separable sides and ends, means to advance and retract the same, and means to connect the pallet with one of the ends to retract the former with the latter.

4. A mold-box comprising sides having longitudinal ribs thereon with a line of holes thereon, ends having loops, and pins insertible through said loops and holes to hold the sides and ends together.

5. An extensible mold-box plate comprising upper and lower plate-sections the former of which may be raised or lowered with respect to the latter, to vary the depth of the box.

809,368. EYEGLASS-GUARD. CHARLES GOODWIN, East Providence, R. I. Filed Dec. 22, 1904. Serial No. 237,980.

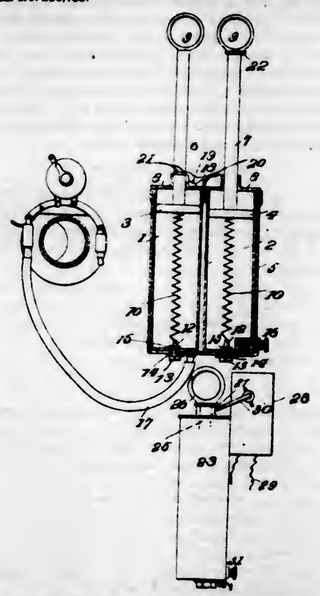


Claim.—1. In a nose-guard for eyeglasses, the combination of a strip or body portion in the form of an oblong rectangular parallelogram having on one long side thereof the bent-up flange *i* and on the opposite side the bent-up flanges *j k*, extending respectively from the ends of said strip or body portion toward the center of said last-mentioned side but leaving an interval at said center, and an offset arm extending angularly from said strip or body portion at said interval, all made of a single piece of metal, substantially as described.

2. In a nose-guard for eyeglasses, the combination of a strip or body portion, the perforated offset arm extending angularly therefrom, the flange *i* along the outer side of said strip or body and bent at an angle therewith, and the two flanges *j k* along the inner side of said strip or body extending from the respective ends of said strip or body to said arm and bent to be parallel with the flange *i*, all made of one piece of metal, substantially as shown.

3. The improved blank for nose-guards for eyeglasses herein described, consisting of a single piece of metal and comprising a strip or body portion in the form of an oblong rectangular parallelogram, an offset arm extending angularly therefrom at one side midway the ends thereof, both said body and arm being in one plane and of the same thickness, and flanges extended in the plane of said body on the opposite straight long sides thereof but of a thickness less than that of said body, substantially as specified.

809,369. AUTOMATIC DEVICE FOR PHOTOGRAPHIC PURPOSES. WILLIAM H. GREENE, Prophetstown, Ill. Filed Apr. 21, 1905. Serial No. 256,753.



Claim.—1. In a device of the class described, the combination of a cylinder and a piston therefor, a second cylinder and piston, means for actuating said pistons, means for holding one of said pistons in a predetermined position, and means operable by the other piston for actuating the holding means coacting with the piston above mentioned.

2. In a device of the class described, the combination of a cylinder, a valved outlet for said cylinder, a second cylinder, spring-actuated pistons operating in the cylinders, piston-rods for said pistons, means for holding the piston-rod of the second-mentioned cylinder in an ascertained position against the tension of the spring cooperating therewith, and means operated by the piston-rod of the first-mentioned cylinder for actuating the means holding the piston-rod of the second-mentioned cylinder in the ascertained position aforesaid.

3. In a device of the class described, the combination of the cylinders 1 and 2, pistons operating in said cylinders, piston-rods extending from the pistons aforesaid, spring means for holding the pistons in a predetermined position, a catch cooperating with the piston-rod of the cylinder 1, means carried by the piston-rod of the cylinder 2 for actuating said catch, and a valve for the cylinder 2.

4. In a device of the class described, the combination of the cylinders 1 and 2, pistons operating in said cylinders, piston-rods extending from the pistons aforesaid, spring means for holding the pistons in a predetermined position, a catch cooperating with the piston-rod of the cylinder 1, means carried by the piston-rod of the cylinder 2 for actuating said catch, a valve for the cylinder 2, and handles operatively connected with the piston-rods of the cylinders 1 and 2.

5. In a device of the class described, the combination of the cylinders 1 and 2, pistons operating in said cylinders, piston-rods for said pistons springs connecting the cylinders and the piston-rods for holding the pistons in a predetermined position, a catch cooperating

with the piston-rod of the cylinder 1, and means carried by the piston-rod of the cylinder 2 for actuating said catch.

6. In a device of the class described, the combination of the cylinders 1 and 2, pistons operating in said cylinders, piston-rods for said pistons, springs connecting the cylinders and the piston-rods for holding the pistons in a predetermined position, a spring-actuated catch cooperating with the piston-rod of the cylinder 1, and means carried by the piston-rod of the cylinder 2 for actuating said catch.

7. In a device of the class described, the combination of the cylinders 1 and 2, pistons operating in said cylinders, piston-rods for said pistons, springs connecting the cylinders of the piston-rods for holding the pistons in a predetermined position, a catch cooperating with the piston-rod of the cylinder 1, and a projection carried by the piston-rod of the cylinder 2 for actuating the catch aforesaid.

8. In a device of the class described, the combination of the cylinders 1 and 2, an outlet-cylinder 1, a valved outlet for the cylinder 2, pistons operating in the cylinders 1 and 2, piston-rods for said pistons, springs arranged in the hollow portions of the piston-rods for holding the pistons at a predetermined position, a catch cooperating with the piston-rod of the cylinder 1, and means carried by the piston-rod of the cylinder 2 for actuating said catch.

809,370. SADDLE TREE OR FRAME. RUDOLF GUILLEAUME, Mülheim-on-the-Rhine, Germany, assignor to Maschinen und Dampfhammerfabrik "Guilleaume Werke" Gesellschaft mit Beschränkter Haftung, Neustadt-on-the-Hardt, Germany. Filed Sept. 16, 1904. Serial No. 224,699.

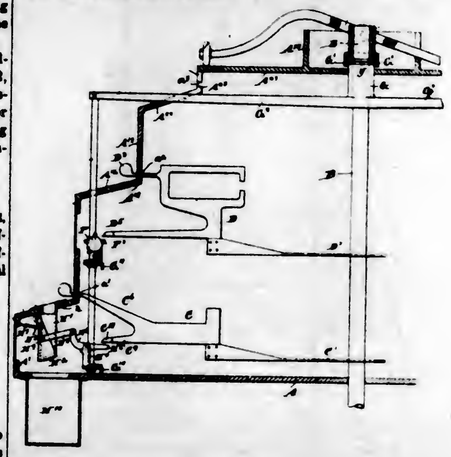
Claim.—1. In a saddle tree or frame, the combination of two sheet-steel side plates having sideway and downward extensions formed integral therewith at their forward ends, said plates being arranged at a short distance apart, being comparatively narrow adjoining said extensions, and having wider portions toward their rear, where they are rounded off, a sheet-steel pommel-plate having sidewardly and downwardly projecting portions at its front fitting the extensions of the side plates, and a sheet-steel cantle-plate in the form of a crescent riveted to the side plates around its inner curve and projecting upward and backward from said side plates, substantially as herein shown and described.

2. In a saddle tree or frame, the combination of two sheet-steel side plates having sideway and downward extensions formed integral therewith at their forward ends, said plates being arranged at a short distance apart, being comparatively narrow adjoining said extensions, and having wider portions toward their rear, where they are rounded off, a sheet-steel pommel-plate having sidewardly and downwardly projecting portions at its front fitting the extensions of the side plates, a series of strengthening-plates riveted to the pommel-plate and side plates, each strengthening-plate having a main portion and sidewardly and downwardly projecting portions at its front end, and a sheet-steel cantle-plate in the form of a crescent riveted to the side plates around its inner curve and projecting upward and backward from said side plates, substantially as herein shown and described.

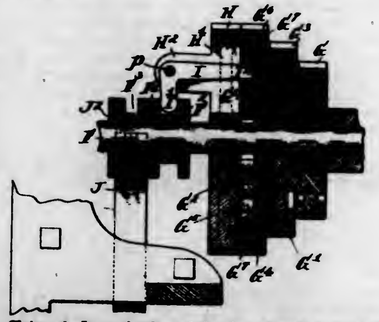
3. In a saddle tree or frame, the combination of two sheet-steel side plates having sideway and downward extensions formed integral therewith at their forward ends, said plates being arranged at a short distance apart, being comparatively narrow adjoining said extensions, and having wider portions toward their rear, where they are rounded off, a sheet-steel pommel-plate having sidewardly and downwardly projecting portions at its front fitting the extensions of the side plates, a series of strengthening-plates riveted to the pommel-plate and side plates, each strengthening-plate having a main portion and sidewardly and downwardly projecting portions at its front end, and being smaller than the one upon which it rests, and a sheet-steel cantle-plate in the form of a crescent riveted to the side plates around its inner curve and projecting upward and backward from said plates, substantially as herein shown and described.

809,371. VOTING-MACHINE. ELMA A. HAGEMEYER, Lyndhurst, N. J., executrix of Charles F. Hemington, deceased, assignor to The Diebold Voting Machine Company, Lyndhurst, N. J., a Corporation of New Jersey. Filed Jan. 20, 1903. Serial No. 139,697.

Claim.—In a voting-machine, a cylindrical casing having an annular slot therein, actuators radially mounted in said casing and each having a portion projecting through said slot whereby it may be swung horizontally, a tube extending from the exterior of said casing to the interior and adapted to receive a ballot, a swinging gate normally closing the lower end of said tube, a support adapted to be moved vertically within said casing, a lever carried by said support, a link from one end of said lever to said gate, the other end of said lever arranged when moved vertically with said support, to contact with one of said actuators presented in its path, and thereby move said gate to open said tube.



809,372. VARIABLE-SPEED GEAR. EMIL A. HOEFER, Freeport, Ill., assignor to Hoefer Manufacturing Company, Freeport, Ill. Filed July 20, 1905. Serial No. 271,268.



Claim.—1. In mechanism of the class described, in combination, a shaft, a plurality of loose gear-wheels, stepped and concentrically mounted thereon, and rotating means adapted to separately and interiorly engage and revolve said gear-wheels, substantially as described.

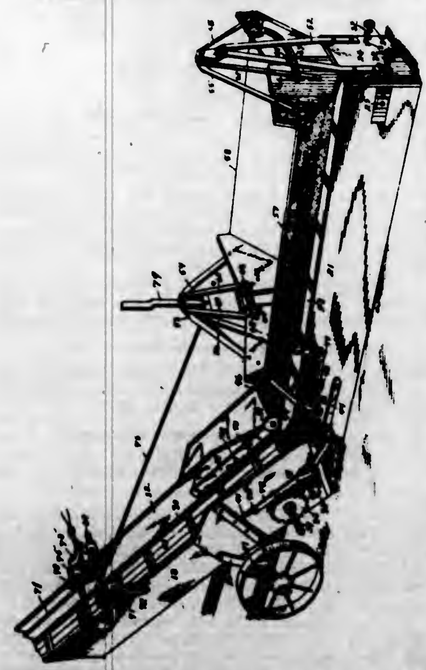
2. In mechanism of the class described, in combination, a shaft, a plurality of gear-wheels, stepped and mounted loose thereon, and a rotatable lever adapted to separately and interiorly engage and drive each of said gear-wheels, substantially as described.

3. In mechanism of the class described, in combination, a non-rotatable shaft, a plurality of separate gear-wheels, stepped and concentrically mounted thereon, and a rotatable part carrying an arm adapted to separately engage and drive each of said gear-wheels, substantially as described.

4. In mechanism of the class described, in combination, a shaft, a plurality of gear-wheels stepped, a peripherally-grooved collar, and a single gear-wheel, all rotatably mounted on said shaft—the last-mentioned gear-wheel being located between the larger of the stepped gear-wheels and the collar—and a bell-crank lever mounted in bearings on and extending transversely through the single gear-wheel and projecting one arm into engagement with the peripheral groove in the collar and having the other arm adapted to engage—by sliding the collar on the shaft—and separately drive each one of said plurality of gear-wheels, substantially as described.

5. In mechanism of the class described, in combination, a shaft F, a collar F′ having a peripheral groove F³ therein and mounted loose thereon, a gear-wheel G provided with an integral or rigid hub G′ terminating, at its free end, in actuating-lugs G² and mounted loose on the shaft F, a gear-wheel G³, of larger diameter than the gear-wheel G, provided with an integral or rigid hub G⁴ terminating, at its free end, in actuating-lugs G⁵ and mounted loose on the hub G′, of the gear-wheel G, a gear-wheel G⁶, of larger diameter than the gear-wheel G³, provided, at its free end, with actuating-lugs G⁷, and mounted loose on the hub G⁴ of the gear-wheel G³, a gear-wheel H having a transverse slot H′ in the web thereof, flanked by two parallel transversely-projecting bearing-lugs H² and mounted loose on the shaft F, a bell-crank lever I pivotally mounted, at its angle and by means of a pintle p, between the lugs H² and projecting one arm I′ into engagement with the groove F³ in the periphery of the collar F′, and the other arm I³ through the slot H′, the latter arm being adapted to engage and separately drive each one of said gear-wheels G G³ G⁶, and a pinion L mounted on the main driving-shaft of the machine and meshing with said gear-wheel H, substantially as described.

809,373. PORTABLE GRAIN-ELEVATOR. DAVID C. HOY and CHARLES F. LADWIG, Horn Springs, Iowa. Filed Mar. 14, 1904. Serial No. 198,116.



Claim.—1. In a device of the class described, the combination of a two-part pivotally-mounted hopper, means for maintaining the parts a slight distance away from each other, and means for maintaining the pivotally-mounted hopper in various positions on its pivotal movement.

2. In a device of the class described, two supports, a two-part hopper pivotally attached to said supports and the parts of the hopper capable of pivotal movement toward and away from each other.

3. In a device of the class described, two supports, a two-part hopper pivotally attached to said supports and the parts of the hopper capable of pivotal movement toward and away from each other, and means for maintaining the parts of the hopper in position relative to each other.

4. In a device of the class described, two supports, a two-part hopper pivotally attached to said supports and the parts of the hopper capable of pivotal movement toward and away from each other, and means connected with said support and with said hopper for maintaining the hopper in position relative to said support.

5. In a device of the class described, two supports, a two-part hopper pivotally attached to said supports and the parts of the hopper capable of pivotal movement toward and away from each other, means for maintaining the parts of the hopper in position relative to each other, and means connected with said support and with said hopper for maintaining the hopper in position relative to said support.

6. In a device of the class described, two supports, a two-part hopper pivotally attached to said supports and the parts of the hopper capable of pivotal movement toward and away from each other, and a conveyer mounted beneath said hopper.

7. In a device of the class described, two supports, a two-part hopper pivotally attached to said supports and the parts of the hopper capable of pivotal movement toward and away from each other, means for maintaining the parts of the hopper in position relative to each other, and a conveyer mounted beneath said hopper.

8. In a device of the class described, two supports, a two-part hopper pivotally attached to said supports and the parts of the hopper capable of pivotal movement toward and away from each other, means connected with said support and with said hopper for maintaining the hopper in position relative to said support, and a conveyer mounted beneath said hopper.

9. In a device of the class described, two supports, a two-part hopper pivotally attached to said supports and the parts of the hopper capable of pivotal movement toward and away from each other, means for maintaining the parts of the hopper in position relative to each other, means connected with said support and with said hopper for maintaining the hopper in position relative to said support, and a conveyer mounted beneath said hopper.

10. In a device of the class described, an elevating conveyer-casing, a lateral conveyer-casing hinged to the elevating conveyer-casing, a conveyer extending longitudinally of said casings and operatively mounted therein, a slidingly-mounted idler connected with the lower end of the elevating conveyer-casing designed to maintain the conveyer in position relative to the bottom of the casings, and a slidingly-mounted guide designed to force the substance to be carried by the conveyer toward the center of it.

11. In a device of the class described, an elevating conveyer-casing, a lateral conveyer-casing hinged to the elevating conveyer-casing, a conveyer extending longitudinally of said casings and operatively mounted therein, a slidingly-mounted idler connected with the lower end of the elevating conveyer-casing designed to maintain the conveyer in position relative to the bottom of the casings, and means for swinging the lateral conveyer-casing toward the elevating conveyer-casing.

12. In a device of the class described, an elevating conveyer-casing, a lateral conveyer-casing hinged to the elevating conveyer-casing, a conveyer extending longitudinally of said casings and operatively mounted therein, a slidingly-mounted idler connected with the lower end of the elevating conveyer-casing designed to maintain the conveyer in position relative to the bottom of the casings, means for swinging the lateral conveyer-casing toward the elevating conveyer-casing, and means for limiting the movement of the lateral conveyer-casing toward the elevating conveyer-casing.

13. In a device of the class described, an elevating conveyer-casing, a lateral conveyer-casing hinged to the elevating conveyer-casing, a conveyer extending longitudinally of said casings and operatively mounted therein, a slidingly-mounted idler connected with the lower end of the elevating conveyer-casing designed to maintain the conveyer in position relative to the bottom of the casings, and means attached to the lateral conveyer-casing and operatively connected with the idler for moving said idler upwardly as the lateral conveyer is swung on its hinge toward the elevating-conveyer.

14. In a device of the class described, an elevating conveyer-casing, a lateral conveyer-casing hinged to the elevating conveyer-casing, a conveyer extending longitudinally of said casings and operatively mounted therein, a wheel-bearing truck connected with the elevating conveyer-casing, means for holding the truck in position relative to the elevating conveyer-casing when the said casing is elevated.

15. In a device of the class described, an elevating conveyer-casing, a lateral conveyer-casing hinged to the elevating conveyer-casing, a conveyer extending longitudinally of said casings and operatively mounted therein, a wheel-bearing truck connected with the

elevating conveyer-casing, and means designed to be connected with a storehouse and to the elevating conveyer-casing and its extensions for raising and lowering the free end of the elevating conveyer-casing.

16. In a device of the class described, an elevating conveyer-casing, a lateral conveyer-casing hinged to the elevating conveyer-casing, a conveyer extending longitudinally of said casings and operatively mounted therein, a wheel-bearing truck connected with the elevating conveyer-casing, means for holding the truck in position relative to the elevating conveyer-casing when the said casing is elevated, and means designed to be connected with a storehouse and to the elevating conveyer-casing and its extensions for raising and lowering the free end of the elevating conveyer-casing.

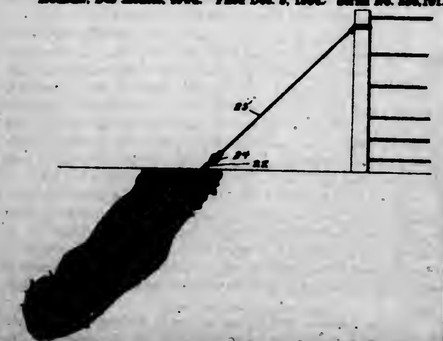
17. In a device of the class described, an elevating conveyer-casing, a lateral conveyer-casing hinged to the elevating conveyer-casing, a conveyer extending longitudinally of said casings and operatively mounted therein, adjustable means connected with the end of the lateral conveyer-casing designed to maintain the conveyer in a taut position, a pivotally-mounted two-part hopper, the parts of said hopper being capable of pivotal movement relative to each other, and means for maintaining the parts of said hopper in position relative to each other.

18. In a device of the class described, an elevating conveyer-casing, a lateral conveyer-casing hinged to the elevating conveyer-casing, a conveyer extending longitudinally of said casings and operatively mounted therein, adjustable means connected with the end of the lateral conveyer-casing designed to maintain the conveyer in a taut position, a pivotally-mounted two-part hopper, the parts of said hopper being capable of pivotal movement relative to each other, means for maintaining the parts of said hopper in position relative to each other, and means for maintaining the hopper in various positions of its pivotal movement.

19. In a device of the class described, an elevating conveyer-casing, a lateral conveyer-casing hinged to the elevating conveyer-casing, a conveyer extending longitudinally of said casings and operatively mounted therein, adjustable means connected with the end of the lateral conveyer-casing designed to maintain the conveyer in a taut position, a pivotally-mounted two-part hopper, the parts of said hopper being capable of pivotal movement relative to each other, means for maintaining the parts of said hopper in position relative to each other, means for maintaining the hopper in various positions of its pivotal movement, and means for swinging the lateral conveyer-casing and the hopper toward the elevating conveyer-casing.

20. In a device of the class described, an elevating conveyer-casing, a lateral conveyer-casing hinged to the elevating conveyer-casing, a conveyer extending longitudinally of said casings and operatively mounted therein, adjustable means connected with the end of the lateral conveyer-casing designed to maintain the conveyer in a taut position, a pivotally-mounted two-part hopper, the parts of said hopper being capable of pivotal movement relative to each other, means for maintaining the parts of said hopper in position relative to each other, means for maintaining the hopper in various positions of its pivotal movement, means for swinging the lateral conveyer-casing and the hopper toward the elevating conveyer-casing, and means for limiting the movement of the hopper and the lateral conveyer-casing relative to the elevating conveyer-casing.

809,374. EARTH-ANCHOR. Ezra C. Holmes and Harry Holmes, Des Moines, Iowa. Filed Dec. 9, 1904. Serial No. 236,161.



Claim.—1. In a device of the class described, a curved body portion, rounded at the ends, rods attached to the body portion at points outside of the center of the body portion.

2. In an earth-anchor, a body portion, rods having diverging ends secured to the body and outside its central portion, and means at the upper ends of said rods to which a cable or rope may be attached.

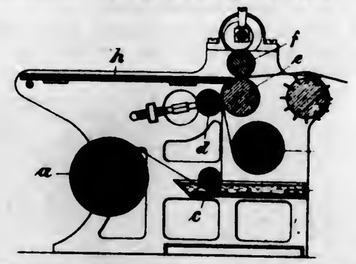
3. In a device of the class described, a curved body portion, loops on each side and at each end of the body portion, a strap passing around each end of the body portion and through the loops, each of said straps having a loop at each end of it, and rods secured to the loops in the ends of the straps having loops at their free ends.

4. In a device of the class described, a curved body portion, loops on each side and at each end of the body portion, a strap passing around each end of the body portion and through the loops, each of said straps having a loop at each end of it, rods secured to the loops in the ends of the straps having loops at their free ends, and means for securing the loops at the free ends of their rods in position relative to each other and for connecting the device to a post or other object.

5. In an anchor-post, a curved body portion, rods attached to the body portion at points outside the center of it.

6. In an anchor-post, a curved body portion, rods attached to the body portion at points outside the center of it, and means connected with said rods to which a cable or rope may be attached.

809,375. COPYING-PRESS. Ferdinand E. Jagenberg, Düsseldorf, Germany. Filed May 12, 1905. Serial No. 260,165.



Claim.—1. A copying-press provided with means for feeding a length of copying-paper through the press, means for copying a writing on one side of the paper, and means for simultaneously gumming a reinforcing-strip along the longitudinal edge on the other side of the paper, substantially as specified.

2. A copying-press provided with a copying-cylinder, a pressure-roller above the same, a feed-table, a paper-carrying reel, and a strip-carrying reel beneath the cylinder, substantially as specified.

809,376. DESK-TABLE. Henry Johnson, Detroit, Mich., assignor to Cadillac Cabinet Company, Detroit, Mich., a Corporation of Michigan. Filed Sept. 28, 1904. Serial No. 226,694.

Claim.—1. The combination with a table comprising a top, side rails, and legs, of a drawer beneath said top having its sides adjacent to said side rails, and slides engaging complementary grooves in the sides of said drawer and the side rails of the said table, and roller-disks engaging kerfs in said slides and adapted to retain the same in engagement with said side rails when said drawer is withdrawn.

3. The combination with a table comprising a top, side rails, and legs, of a drawer arranged beneath said top adjacent to said side rails, slides engaging complementary grooves in said drawer and side rails, shoulders on said slides adapted to impinge against the forward legs to limit the outward movement of said slides, pins in said drawer engaging slots in said slides for limiting the outward movement of the former in relation to the latter, and roller-disks engaging kerfs in said slides and adapted to retain the same in engagement with said side rails when said drawer is withdrawn.

809,377. CONDUCTOR'S CASH-FARE-RECEIPT REGISTER. William W. Kay, St. Louis, Mo. Filed Nov. 12, 1903. Serial No. 181,089.

Claim.—1. In a conductor's cash-fare-receipt register, a suitable casing, means for advancing therein an original record strip or tape and a duplicate strip corresponding thereto, means for simultaneously imprinting the cash fare upon both the original and duplicate strip, and mechanism for recording the time of said imprint upon the duplicate strip only, substantially as set forth.

2. In a conductor's cash-fare-receipt register, a suitable casing, means for advancing therein an original record strip or tape and a duplicate strip corresponding thereto, means for imprinting the cash fare upon both the original and duplicate, and mechanism for imprinting the station or destination to which said fare corresponds upon said duplicate strip only, substantially as set forth.

3. In a conductor's cash-fair-receipt register, a suitable casing, means for advancing therein an original record strip or tape and a duplicate strip corresponding thereto, means for imprinting the cash fare upon both the original and duplicate, and mechanism for recording the time of said imprint and the station or destination to which said fare corresponds, upon said duplicate strip only, substantially as set forth.

4. In a conductor's cash-fare-receipt register, a suitable casing, means for advancing therein an original record strip or tape and a duplicate strip corresponding thereto, the latter being wholly confined within the casing, means for simultaneously imprinting the cash fare upon both the original and duplicate, and mechanism for recording the time of said imprint upon the duplicate strip only, the original being adapted to be withdrawn from the casing after the record has been impressed thereon, substantially as set forth.

5. A conductor's cash-fare-receipt register, comprising a suitable casing, a roll carrying two strips of paper within said casing, an ink-ribbon extending alongside of one of said strips of paper after it has been withdrawn from said roll, another ink-ribbon of limited width extending across and between said strips of paper, suitable feed-rolls between which said strips pass, a printing or stamping device for inditing upon one strip of paper only the amount of cash fare received from each passenger, means for inditing upon the other strip of paper the time of receipt of cash fare from passengers, and means for inditing the station identification-marks upon the last-mentioned strip of paper, substantially as described.

6. In a conductor's cash-fare-receipt register, a suitable casing, means for advancing therein an original and duplicate record strip or tape, the original being adapted to be progressively withdrawn from the casing, an inking-ribbon for the duplicate strip, an inking-ribbon for the original strip disposed at an angle to the first-mentioned ribbon, means for imprinting the cash fare upon both the original and duplicate strips, and mechanism for recording the time of such imprint upon the duplicate strip only, and likewise the station or destination to which said fare corresponds, substantially as set forth.

7. In a conductor's cash-fare-receipt register, a casing, means for advancing, in parallel, an original and a duplicate record-strip, cash-fare-printing wheels which are independently adjustable to set up different amounts in the printing-line, means for making a printing impression upon both of said strips from the same type in the printing-line of the cash-fare-printing wheels, time-printing wheels, for making a printing impression upon one of said strips coincidently with the recording of the amount of the cash fare received, and a time-train for driving said time-printing wheels; substantially as described.

8. In a machine of the character described, the combination with printing-wheels which are independently adjustable to set up characters representing varying amounts in the printing-line, time-printing wheels, a clock-motor for driving said time-printing wheels, means for advancing two strips past the printing-lines of both sets of printing-wheels, and an operating-handle for making a printing impression on both of said strips from said cash-fare-printing wheels and an impression upon only one of said strips from the time-printing wheels; substantially as described.

9. In a machine of the character described, the combination with printing-wheels which are independently adjustable to set up characters representing station-numbers, in the printing-line, time-printing wheels, a clock-motor for driving said time-printing wheels, means for advancing an original record-strip and a parallel duplicate strip past the printing-lines of both sets of printing-wheels, both of said strips being fed together past said printing-wheels, and an operating-handle for making a printing impression on said stripe from said printing-wheels; substantially as described.

10. In an apparatus of the character described, the combination with time-printing wheels, a clock-motor for driving the same, independently-adjutable cash-fare-printing wheels, independently-adjustable station-number-printing wheels, means for advancing an original record-strip and a duplicate strip past the printing-lines of all of said printing-wheels, both of said stripe being fed together past said printing-wheels, and means for making printing impressions on said strips from said printing-wheels; substantially as described.

11. In a conductor's register, the combination with means for supporting a record-strip, of printing mechanisms for recording cash fares on said strip, printing mechanisms for recording the time on said strip, a clock mechanism in connection with the type-wheels of said last-mentioned printing mechanism, means for making printing impressions on said record-strip, and a printing-wheel for printing the numbers of the stations between which the cash fare recorded on the strip is applicable, the operation of said station-printing wheel operating a line-spacing mechanism for feeding the record-strip; substantially as described.

12. In a conductor's cash-fare register, the combination with printing-wheels, means for operating said printing-wheels to set up the amount of fare received in the printing-line, printing-wheels located adjacent to said first-mentioned printing-wheels, clock mechanism for driving the last-mentioned printing-wheels, a platen, means for initially moving said platen to make a printing impression, and means which are effective after said initial movement, for moving the platen to and from contact with the printing-type; substantially as described.

13. In a conductor's register, the combination with two sets of printing-wheels, one of said sets being driven by a clock mechanism, and the other manually adjusted to indicate the amount of fare received, means for supporting a record-strip, a printing-platen, a cam for operating said platen, and means whereby the initial rotation of said cam will not effect a printing impression, said cam being caused to complete its rotative movement independently of the control of the operator so as to instantly make the printing impression and raise the platen from the printing-type after the printing impression is made; substantially as described.

14. In a conductor's register, the combination with printing-type, of a platen having a reciprocatory movement, a cam for vibrating said platen, a drive-wheel for said cam, and a pawl-and-ratchet connection cooperating with said drive-wheel whereby a portion of the revolution of the cam is independent of the control of the operator; substantially as described.

15. In a conductor's register, the combination with printing-type, of a reciprocatory platen for making the printing impression from said type, a cam for reciprocating said platen, a gear carrying said cam, the second gear in mesh with the first-mentioned gear, an operating-handle, and a pawl-and-ratchet mechanism interposed between the operating-handle and said second gear; substantially as described.

16. In a conductor's register, the combination with printing-type, of a platen for making a printing impression therefrom, a cam for operating said platen, a spring connected to said cam for holding the platen in an elevated position, and a ratchet-and-pawl mechan-

lem for partially rotating said cam and placing said spring under tension so that the spring will make a printing impression; substantially as described.

17. In a conductor's register, the combination with printing-type, of a reciprocatory platen, a cam for operating said platen, a crank-arm connected to said cam, a spring connected to said crank-arm, and a ratchet-and-pawl mechanism for driving said cam and crank-arm around until the crank-arm passes the position of dead-centers whereby the power stored in said spring will act to move the crank-arm and cam to complete the rotative movement thereof and effect an instantaneous printing impression; substantially as described.

18. In a conductor's register, the combination with printing-type, of a platen-actuating mechanism, a paper-feed roll, means for locking the paper-feed roll after a limited peripheral distance has been traversed, and means operated by the platen-actuating mechanism for releasing the paper-feed roll; substantially as described.

19. In a conductor's register, the combination with printing-type, a platen, platen-actuating mechanism comprising a gear with a projection thereon, a paper-feed roll, and a lock coöperating with said paper-feed roll, said lock having a tailpiece which is located in the path of said projection when the feed-roll is locked, whereby the operation of the platen-actuating mechanism will operate said lock to release the paper-feed roll; substantially as described.

20. In a conductor's register, the combination of a paper-feed roll having a friction-pulley at one end, locking projections adjacent said friction-pulley, a locking-plate in engagement with said friction-pulley and provided with a complementary locking projection designed to coöperate with the locking projections on the paper-feed roll, and means for moving said locking-plate out of locking position; substantially as described.

21. In a conductor's register, the combination of a paper-feed roll, means for supporting a record-strip, a friction-pulley on the end of said paper-feed roll, locking projections also carried by said paper-feed roll, a locking-plate in frictional engagement with said pulley, said plate having a complementary locking projection to arrest the movement of the feed-roll, printing mechanism for making the printing impression on the record-strip, and means whereby upon the actuation of said printing mechanism said locking-plate is operated to release the paper-feed roll; substantially as described.

22. In a conductor's register, the combination of means for supporting a record-strip, of a printing-wheel for printing the numbers of stations on said record-strip, a shaft upon which said printing-wheel is mounted, a universal coupling for supporting one end of said shaft, and an operating-handle on the other end of said shaft for moving the same to cause its carried printing-wheel to make a printing impression on the record-strip; substantially as described.

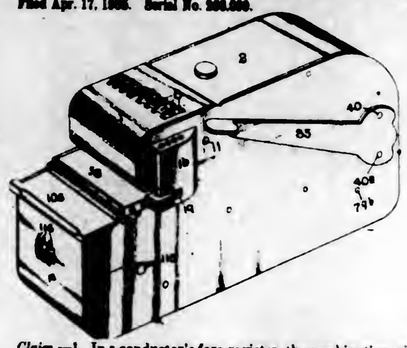
23. In a conductor's register, the combination with nested indicator-wheels, a shaft capable of longitudinal and rotary motion, said shaft having a projection designed to engage and successively operate the said indicator-wheels, printing-wheels mounted on said shaft, and a complementary projection on said shaft for engaging and operating the printing-wheels corresponding to the position occupied by the indicator-wheels; substantially as described.

24. In a conductor's register, the combination with nested cup-shaped indicator-wheels, of spring-pressed devices for holding them in adjusted positions, a shaft capable of longitudinal and rotary movement and provided with a projection for separately operating said disks, printing-wheels mounted on said shaft, and a complementary projection on the shaft for engaging and operating the printing-wheels to correspond with the positions of their respective disks; substantially as described

25. In a conductor's register, the combination with two sets of printing-type, one for impressing the cash fares on the record-strip and the other for impressing the time upon said record-strip, a platen for making a printing impression from said type, an independently-operable printing-wheel for printing the numbers of the stations between which the cash fare recorded is applicable, a receiving-spool for the record-strip, and means operated by the last-mentioned printing mechanism for driving said receiving-spool to wind up the record-strip; substantially as described.

26. In a conductor's register, the combination with cash-fare-printing wheels, time-printing wheels, a platen for making a printing impression on said wheels, means for supporting a permanent record-strip, means for printing the numbers of the stations on said permanent record-strip between which stations the cash fare paid is applicable, means operated by the last-mentioned printing mechanism for winding up the record-strip, means for supporting a second record-strip which is issued from the machine, a paper-feed roll therefor, and means for locking said paper-feed roll against movement after a predetermined length of said record-strip is paid out by the machine; substantially as described.

809,378. FARE-REGISTER. WILLIAM W. KAY, St. Louis, Mo. Filed Apr. 17, 1905. Serial No. 256,080.



Claim.—1. In a conductor's fare-register, the combination with a totalizer, means for registering in said totalizer and recording on a strip of paper the number of tickets or cash-fare receipts canceled by the machine, canceling devices operable in connection with said registering and recording means, time-printing wheels, and means for impressing the time on the record-strip in connection with each ticket or cash-fare receipt registered, recorded and canceled; substantially as described.

2. In a conductor's fare-register, the combination with means for registering and recording the number of tickets or cash-fare receipts lifted, time-printing wheels, means for impressing the time on the record-strip in connection with the registration and recordation of each ticket or cash-fare receipt lifted, station-number-printing wheels, and means for making a printing impression upon said record-strip from said station-number-printing wheels; substantially as described.

3. In a conductor's fare-register, the combination with means for advancing a record-strip, of means for advancing a hat-check strip, station-number-printing wheels, register-printing wheels, time-printing wheels, and means for impressing the station-numbers and register-numbers on said stripe, said means impressing the time on the record-strip only; substantially as described.

4. In a conductor's fare-register, the combination with each-fare-printing wheels, of time-printing wheels, means for advancing a record-strip past said cash-fare-printing wheels and said time-printing wheels, means for impressing the time on the record-strip in connection with each cash-fare item recorded, and independent mechanism for impressing the cash-fare-printing wheels on said record-strip; substantially as described.

5. In a conductor's fare-register, the combination with means for supporting a record-strip, printing mechanism for recording cash fares on said strip, independent printing mechanism for recording the time on said strip, a time-train for driving the type-wheels of said last-mentioned printing mechanism, and independently-operable means for making printing impressions from said wheels on said record-strip; substantially as described.

6. In a conductor's fare-register, the combination with printing mechanism for recording and registering tickets and cash-fare receipts collected by the conductor, means for feeding a record-strip, a clock mechanism, printing-wheels driven by said clock mechanism, and means whereby said clock-driven printing-wheels are caused to make a printing impression; substantially as described.

7. In a conductor's fare-register, the combination with printing mechanism for recording and registering the serial numbers of tickets and cash-fare receipts collected by the conductor, means for feeding a record-strip, a clock mechanism, printing-wheels driven by said clock mechanism, banks of independently-rotatable station-number-printing wheels, and means whereby said clock-driven printing-wheels and said station-number-printing wheels are caused to make a printing impression; substantially as described.

8. In a conductor's fare-register, the combination with register-printing wheels, station-number-printing wheels, time-printing wheels, and cash-fare-printing wheels, of means for feeding a record-strip, and independently-operable means for making a printing impression from the cash-fare-printing wheels upon said record-strip; substantially as described.

9. In a conductor's fare-register, the combination with a register-printing mechanism, a cash-fare-receipt-printing mechanism, and a time-printing mechanism, of means for supporting a record-strip, and a hat-check strip, one of which is retained in the register, means for issuing the other of said stripe from the register, an operating-handle, and means for effecting a printing impression upon said stripe from said handle and moving both of said stripe together past the printing-wheels; substantially as described.

10. In a conductor's fare-register, the combination with ticket-canceling devices, of a printing register and recorder operating in conjunction therewith, means for effecting a printing impression from said register to make said record coincidently with the cancellation of a ticket, time-printing wheels, and means for feeding a record-strip past said time-printing wheels and said register-printing wheels; substantially as described.

11. In a conductor's fare-register, the combination with ticket-canceling devices, of register-printing wheels, station-number-printing wheels and time-printing wheels, means for feeding a record-strip past said printing-wheels, and means for making a printing impression from said printing-wheels upon said record-strip; substantially as described.

12. In a conductor's fare-register, the combination with ticket-canceling devices, of register-printing wheels, time-printing wheels, and cash-fare-printing wheels, means for feeding a record-strip past said printing-wheels, means for impressing the register and time printing wheels upon said record-strip, and independent means for impressing the cash-fare-printing wheels upon said record-strip; substantially as described.

13. In a conductor's fare-register, the combination with means for recording cash fares, of clock mechanism, means operable independently of the said cash-fare-recording mechanism for impressing the time on the record-strip in connection with each cash-fare item recorded, and printing-wheels for printing the numbers of the stations between which the cash-fare item recorded on said strip is applicable; substantially as described.

14. In a conductor's fare-register, the combination with means for advancing the record-strip, cash-fare-printing wheels for making a record of the cash fare received upon said strip and upon another strip, which other strip is issued from the machine, register-printing wheels, station-number-printing wheels, time-printing wheels, and means for making a printing impression from said last three mentioned printing-wheels upon said record-strip; substantially as described.

15. In a conductor's fare-register, the combination with a cash-fare-printing wheels for making a record of cash fares received upon two stripe of paper, one of which is issued from the machine and the other of which is retained in the machine to make a permanent record of the transaction, register-printing wheels, station-number-printing wheels, time-printing wheels, means for making a printing impression from said last-mentioned printing-wheels upon said permanent record-strip but not upon the cash-fare receipt issued from the machine, and a spool for supporting a roll of hat-checks, upon which hat-checks the station-numbers and register-number are printed by the said station-number-printing wheels, and the said register-printing wheels; substantially as described.

16. In a conductor's fare-register, the combination with ticket or cash-fare-receipt canceling devices, means for marking said tickets or cash-fare receipts with numbers to identify the order of their cancellation, time-printing wheels, a time-train for driving said printing wheels, and means for operating said canceling and marking devices coincidently with making a printing impression with said time-printing wheels; substantially as described.

17. In a conductor's fare-register, the combination with ticket or cash-fare-receipt canceling devices, means for marking said tickets or cash-fare receipts with numbers to identify the order of their cancellation, means for recording the time of such cancellation, and means for marking the station-number in connection with the time of cancellation; substantially as described.

18. In a conductor's fare-register, the combination with ticket-canceling devices, of register-printing wheels, means for effecting a printing impression from said wheels upon said ticket and also upon a hat-check, coincidently with the operation of said canceling devices, means for feeding the hat-check from a roll past the register-printing wheels, and means for automatically setting said register-printing wheels after each printing impression; substantially as described.

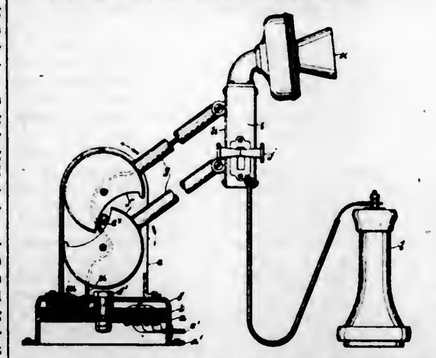
19. In a conductor's fare-register, the combination with ticket and cash-fare-receipt canceling devices, means for marking said tickets or cash-fare receipts which are canceled with identifying-numbers, means for similarly marking a check to be issued for the ticket or cash-fare receipt canceled, and means for recording the time of issuance of said check; substantially as described.

20. In a conductor's fare-register, the combination with cash-fare-receipt-printing mechanism for printing the amount of a cash-fare receipt on a receipt to be issued and canceled, said printing mechanism also printing said amount on a record retained in the machine, means for canceling said receipt, and means for recording the time of such cancellation; substantially as described.

21. In a conductor's fare-register, the combination with cash-fare-receipt-printing mechanism for printing the amount of a cash-fare receipt on a receipt to be issued and canceled, said printing mechanism also printing said amount on a record retained in the machine, means for canceling said receipt, means for recording the time of such cancellation, and means for recording the station-numbers between which the cash fare is applicable; substantially as described.

22. In a conductor's fare-register, the combination with cash-fare-receipt-printing mechanism for printing the amount of a cash-fare receipt on a receipt to be issued and canceled, said printing mechanism also printing said amount on a record retained in the machine, means for canceling said receipt, means for recording the time of such cancellation, and means for recording the station-numbers between which the cash fare is applicable, said means also printing said station-numbers on a check to be issued for said canceled receipt; substantially as described.

809,379. ADJUSTABLE SUPPORT FOR TELEPHONES. HERBERT L. KNIGHT and BURTON W. SWEET, Cleveland, Ohio, assignors to The Williams-Abbott Electric Company, Cleveland, Ohio, a Corporation of Ohio. Filed Apr. 15, 1905. Serial No. 256,774.



Claim.—1. In an adjustable support for a telephone, the combination with friction-blocks pivotally mounted in a vertical plane, means for opposing the movement thereof upon their pivotal mountings, supporting-arms extending from said friction-blocks, and a telephone-support carried by said supporting-arms in any desired position of vertical adjustment, substantially as set forth.

2. In an adjustable support for a telephone, the combination with friction-blocks pivotally mounted in a vertical plane, means for opposing the movement thereof upon their pivotal mountings, supporting-arms extending from said friction-blocks, a telephone-support carried by said supporting-arms in any desired position of vertical adjustment, a base portion, and a horizontally-adjustable mounting for the friction-blocks, whereby a supported telephone may be actuated into the desired positions of vertical and horizontal adjustment, substantially as set forth.

3. In an adjustable support for telephones, the combination with a stationary base portion, of a rotatable base portion pivotally mounted thereon, pivotally-mounted friction-blocks and means for opposing their rotation in vertical planes, supporting-arms carried by said friction-blocks, and a supporting plate or bracket mounted upon said arms for carrying the telephone, whereby said instrument is made adjustable in vertical and horizontal positions and is retained in place, substantially as set forth.

4. In an adjustable supporting device for telephones, the combination with rotatably-mounted friction-blocks, of side pieces bearing against the same and normally retaining said blocks against rotation, clamping means associated with said side pieces, parallel arms extending from said friction-blocks, and a bracket or supporting-plate for the telephone pivotally secured to the outer extremities

of said supporting-arms whereon the telephone is adapted to be

---

862,882

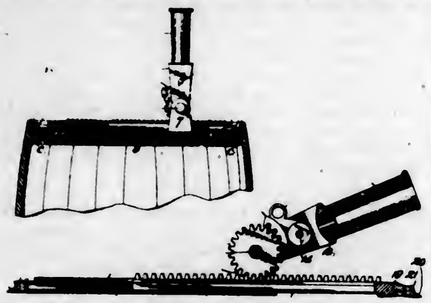
between the retainers, and devices actuated by the ejector for posi-

sure-controlling device for admitting a fluid under pressure into the

of said supporting-arms wherein the telephone is adapted to be mounted, substantially as set forth.

5. The combination in an adjustable supporting device with a stationary base portion, of a pivotally-mounted carrying part thereon, two coacting friction-blocks pivotally supported upon the carrying part, friction-surfaces engaging the same, clamping means for forcibly engaging the latter with the friction-blocks, parallel supporting-arms extending from said friction-blocks, and a bracket or supporting-plate for a telephone instrument pivotally connected at the extremities of said supporting-arms, substantially as set forth.

809,380. **BARREL-OPENER.** JAMES S. KNIGHT and MYRON B. RUSS, Kansas City, Mo. Filed May 20, 1905. Serial No. 261,949.



Claim.—1. A barrel-opener, comprising a pair of members fitting slidingly together and terminating at their outer ends in heads having wedges at their outer margins, a lever pivotally supported from one of said members, and means whereby pivotal movement of said lever in one direction shall slide said members and thereby increase the distance between their heads.

2. A barrel-opener, comprising a pair of members fitting slidingly together and terminating at their outer ends in heads having wedges at their outer margins and shoulders inward of and above said wedges, a lever pivotally supported from one of said members, and means whereby pivotal movement of said lever in one direction shall slide said members and thereby increase the distance between their heads.

3. A barrel-opener, comprising a pair of members fitting slidingly together and terminating at their outer ends in segmental heads having wedges at their outer margins, a lever pivotally supported from one of said members, a gravity-dog carried by said lever, and means actuated by said dog as the lever is swung forward to slide said members and increase the distance between their heads.

4. A barrel-opener, comprising a pair of members fitting slidingly together and terminating at their outer ends in heads having wedges at their outer margins, one of said members being provided with cog-teeth, a cog-wheel engaging said teeth and having rotary movement only, a lever pivoted to rotate around the axis of the wheel, and a gravity-dog carried by said lever and adapted as the latter is swung forward to engage and rotate said wheel.

809,381. **SOLDERING-FLUX.** OSCAR J. LANIGAN, Chicago, Ill. Filed Mar. 3, 1903. Serial No. 146,269.

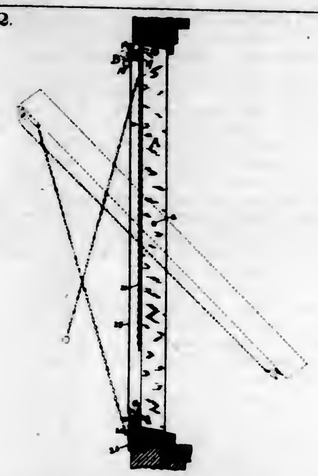
Claim.—A soldering-flux comprising red oil, resin and ammoniated water, substantially as described.

809,382. **WINDOW-LOCKING MEANS.** THOMAS LEE, Horse City, Ohio. Filed Aug. 9, 1905. Serial No. 273,226.

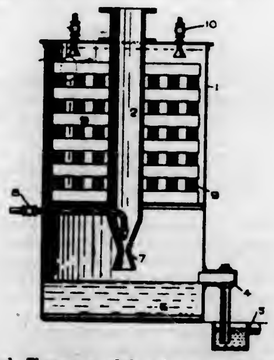
Claim.—1. In combination with a window, an upper window-locking catch consisting of a bolt, a keeper for it, a weighted lever to hold this bolt normally in locking engagement with its keeper, a lower window-locking catch, a link connecting it with the weighted lever of the upper catch and means to manipulate this latter to unlock it and simultaneously also the lower catch.

2. In combination with a window, a locking-bolt at its upper edge, a keeper for it, a weighted lever to hold it normally in locking engagement with its keeper, a weighted hook at the lower edge of the window, a keeper for it, a link to connect this hook with the weighted lever of the upper catch and means to manipulate this latter.

809,382.



809,383. **METHOD OF CLEANSING MANUFACTURED GASES.** LEON P. LOWE, San Francisco, Cal. Filed June 17, 1903. Serial No. 161,795.



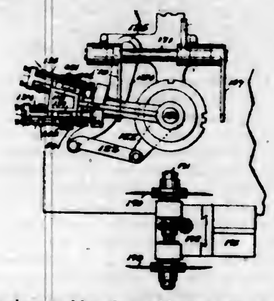
Claim.—1. The process of cleansing gas which consists in subjecting it to compression and frictional resistance and simultaneously saturating it with steam, thereby greatly increasing the several masses of the impurities, and projecting the mixture of gas and impurities downward toward the surface of a continuous body of water with sufficient velocity to throw said impurities into contact with the water, the lighter gas escaping said contact, and withdrawing the purified gas, substantially as described.

2. The process of cleansing gas which consists in subjecting it to compression and frictional resistance and simultaneously saturating it with steam, thereby greatly increasing the several masses of the impurities, and projecting the mixture of gas and impurities downward toward the surface of a continuous body of water with sufficient velocity to throw said impurities into contact with the water, the lighter gas escaping said contact, withdrawing the purified gas, and removing the steam, substantially as described.

809,384. **CIGAR-MACHINE.** WILLIAM S. LOCKETT, East Orange, N. J., assignor to International Cigar Machinery Company, New York, N. Y., a Corporation of New Jersey. Filed Apr. 14, 1904. Serial No. 203,196.

Claim.—1. In a cigar-machine, the combination with a carrier adapted to carry bunches or cigars, said carriers having sets of retainers, of ejectors one for each set, the ejector for each set being located between the retainers of that set, and means for positively swinging the sets of retainers to open and close them.

2. In a cigar-machine, the combination with a carrier having a set of retainers for carrying bunches or cigars, of an ejector located between the retainers, and devices actuated by the ejector for positively opening and closing the retainers.



3. In a cigar-machine, the combination with a carrier adapted to carry bunches or cigars, said carriers having two sets of retainers, of two ejectors, one for each set, the ejector for each set being located between the retainers of that set, and devices operated by the ejectors for positively opening and closing the retainers.

4. In a cigar-machine, the combination with a carrier having two sets of pivoted retaining-fingers for carrying bunches or cigars, two ejectors one for each set of fingers, and means actuated by the ejectors for positively opening and closing the fingers.

5. In a cigar-machine, the combination with a carrier having retainers adapted to carry bunches or cigars, of an ejector located between the retainers, operating means for the ejector, means carried by the ejector and operating on the interior of the retainers to open the same, and means carried by the ejector and operating on the exterior of the retainers to close the same.

6. In a cigar-machine, the combination with a carrier having retainers for carrying bunches or cigars, of an ejector mounted between the retainers, operating means for the ejector, a cross-bar mounted on the ejector and operating on the interior of the retainers to open the same, and a cross-bar mounted on the ejector and operating on the exterior of the retainers to close the same.

7. In a cigar-machine, the combination with a carrier adapted to carry bunches or cigars, said carrier having two sets of retainers, of two ejectors, one for each set, the ejector for each set being mounted between the retainers of that set, and positively-operated means actuated by the ejectors for closing the retainers.

8. In a cigar-machine, the combination with a carrier adapted to carry bunches or cigars, said carrier having a set of retainers, an ejector mounted between the retainers, means for opening the retainers, and a cross-bar carried by the ejector and operating on the exterior of the ejector to close the same.

9. In a cigar-machine, the combination with a carrier adapted to carry bunches or cigars, said carrier having two sets of retainers, two ejectors, one for each set of retainers, the ejector for each set being mounted between the retainers of that set, cross-bars carried by the ejectors and operating on the interior of the retainers, cross-bars carried by the ejectors and operating on the exterior of the retainers, and cam-surfaces on the exterior of the retainers with which said cross-bars coöperate.

10. In a cigar-machine, the combination with a movable bunch-carrier, a cutter in the path of the carrier, and coöperating yielding cutting-plates mounted on the carrier, substantially as described.

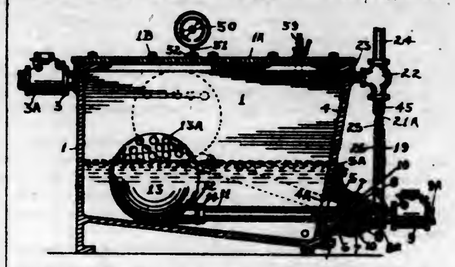
11. In a cigar-machine, the combination with a movable bunch-carrier, of a rotating cutter in the path of movement of the carrier, and coöperating yielding cutting-plates mounted on the carrier, substantially as described.

12. In a cigar-machine, the combination with a movable bunch-carrier, of a cutter in the path of movement of the carrier, and recessed spring-plates mounted on each end of the carrier and coöperating with the cutter, substantially as described.

13. In a cigar-machine, the combination with a movable bunch-carrier, of a rotating cutter in the path of movement of the carrier, and recessed spring-plates mounted on each end of the carrier and coöperating with the cutter, substantially as described.

809,385. **APPARATUS FOR DISCHARGING LIQUIDS IN VACUO.** JARARD W. LETTON, Portsmouth, Va. Filed Oct. 28, 1904. Serial No. 230,263.

Claim.—1. A vacuum-trap comprising a casing having a pressure-controlling device for admitting a fluid under pressure into the casing a vacuum-controlling device for exhausting the casing of pressure, and mechanism controlling the said devices to alternately connect the casing with a pressure-supply and a vacuum apparatus.



2. A vacuum-trap comprising a casing having an inlet and a discharge, a pressure-controlling device for admitting a fluid under pressure into the said casing, a vacuum-controlling device for exhausting the casing of pressure, and a float-controlled mechanism actuated by the rising and falling of the liquid in the said casing and controlling the said devices.

3. A vacuum-trap comprising a casing having an inlet and a discharge, a pressure-controlling device for admitting a fluid under pressure into the said casing, a vacuum-controlling device for exhausting the casing of pressure, and a float-controlled mechanism actuated by the rising and falling of the liquid in the said casing and controlling the safety devices, to alternately connect the said casing with pressure-supply and a vacuum apparatus.

4. In an apparatus of the class described comprising a liquid-receptacle, means for connecting the said receptacle to a vacuum, valve means forming an outlet for the receptacle to the atmosphere, means for alternately closing the said vacuum connection and the outlet, and exterior controlling means for governing the period of opening and closing to the vacuum source and the outlet to the atmosphere; as described.

5. In an apparatus for receiving and discharging liquids from separators and the like comprising a receptacle having a normally open connection to the vacuum and closed to the atmosphere, means for closing the vacuum connection when discharging to the atmosphere and in a reverse order, and float-actuated exterior means connected to the vacuum source and the atmosphere for controlling the said opening and closing of the receptacle to the vacuum and the exterior thereof; as described.

6. In an apparatus of the class described, of a closed receptacle having a normally open inlet connection to a vacuum and liquid source, a normally closed outlet connection to the atmosphere, automatic means for closing the vacuum and liquid connection when the said atmospheric connection is open, means for closing the said connections in a reverse order, means for closing one connection before opening the other, exterior-disposed vacuum and atmospheric-pressure communicating means actuated by the float for controlling the receptacle connections, and pressure means for forcing the receptacle contents to the atmosphere; as described.

7. In an apparatus of the class described comprising a closed vacuous receptacle, means for receiving liquids from oil separators and extractors under a vacuum from and discharging the same to the atmosphere, a vacuum-communicating connection to the vacuum source and the liquid, a discharge connection normally closed to the receptacle interior, float-controlled valve means connected to the vacuous-receptacle interior and the atmosphere and governing the said connections, means for opening the receptacle interior to the vacuum during the filling thereof, means for admitting atmospheric pressure to the said receptacle when discharging, and exterior means for causing a discharge of the receptacle independent of the float; as described.

8. In an apparatus of the class described comprising a closed liquid-receptacle having connection to a source of vacuum and the liquid, an outlet connection normally closed by atmospheric pressure, a liquid-level-actuated exteriorly-disposed valve means connected to the vacuum and the atmosphere, means controlled by the said valve for excluding the atmosphere when the receptacle is filling with the liquid, means for admitting the atmosphere when the receptacle is discharging, and automatic means controlled by the float for closing one receptacle connection before another is open; as described.

9. In an apparatus of the class described comprising a vacuous

receptacle having a normally open vacuum-communicating liquid-inlet, an outlet to the exterior of the receptacle normally closed by atmospheric pressure, equalizing means connected to the vacuum source and the receptacle interior, means controlled by the said equalizing means for maintaining a vacuum when the receptacle is filling with the liquid, means controlled by the equalizing means to close the vacuum connection and admit atmospheric air when the receptacle is discharging to the exterior of the said receptacle, liquid-level controlling means for automatically operating the equalizing means and means exterior to the receptacle for actuating the equalizing means independent of the liquid-level in the receptacle; as described.

10. In an apparatus for discharging liquids *in vacuo*, comprising a closed receptacle having an outlet connection and a normally open vacuum-communicating inlet-valve, a float-controlled snifting-valve normally open to the vacuum, means for simultaneously closing the said snifting-valve to the vacuum and opening thereof to the atmosphere; as described.

11 In an apparatus for discharging liquids under a vacuum comprising a vacuum-chamber having inlet and outlet valves normally closed by atmospheric pressure, an exteriorly-disposed snifting-valve having a normal communication with the said chamber and the vacuum source, float controlling means for simultaneously closing the said snifting-valve to the vacuum connection and opening the same to the atmosphere when discharging the chamber, and means for delaying the full opening of the snifting-valve; as described.

12. In an apparatus for discharging liquids *in vacuo* comprising a closed vacuous receptacle, a vacuum-connected inlet-valve normally discharging into the said vacuous receptacle, a discharge-valve normally closed by atmospheric pressure, a float-actuated controlling-valve normally in communication with the vacuum and the receptacle interior, means for simultaneously closing the said controlling-valve to the vacuum and the receptacle and admitting the atmosphere thereto during a discharge of the liquid, and means for forcing the discharge of the receptacle by pressure; as described.

13. In an apparatus for collecting and discharging liquids under a vacuum comprising a vacuous receiving-chamber having a liquid-inlet valve normally open to the said chamber and the vacuum source, means for closing the said inlet-valve when air is admitted to the chamber, a periodic-discharge valve normally closed to the interior of the chamber by the atmosphere, a float-actuated controlling-valve connected to the vacuum source and the interior of the chamber, means for causing the said controlling-valve to remain open to the vacuum and the chamber during the filling thereof, and means for closing the controlling-valve to the vacuum and admitting air to the chamber during its discharge; as described.

14. In an apparatus for discharging accumulated liquids under a vacuum the combination with a normally vacuous receptacle, a vacuum-connected normally open inlet-valve, a normally closed receptacle discharge-valve, a float-controlled normally open angle-valve for connection to the vacuum source and the receptacle interior, means for simultaneously closing the said angle-valve to the vacuum and the said receptacle interior and admitting the atmosphere thereto, means for closing the said inlet-valve to the vacuum and liquid by atmospheric pressure, and means for opening the said discharge-valve by the weight of the liquid for emptying the receptacle when the atmosphere is admitted; as described.

15. In an apparatus for discharging liquids under a vacuum, the combination with a vacuous-closed receptacle, a vacuum-connected normally open inlet-valve, a normally closed discharge-valve, an angle controlling snifting-valve connected to and normally open to the vacuum and the interior of the receptacle, means for simultaneously closing the said controlling-valve and admitting the atmosphere to the receptacle, float means for regulating the opening and closing of the controlling-valve, and means for closing the vacuum connections of the receptacle by automatic means when discharging; as described.

16. In an apparatus for automatically discharging liquids under a vacuum, comprising a closed chamber having a vacuum-connected liquid-inlet valve, a normally closed outlet-valve, an opening at one end of the receptacle, a flanged exteriorly-disposed plug-casing having an inward divergent cavity, a plug-seat centrally located in the said cavity, a float-actuated apertured plug normally oscillating in the seat during changes in the liquid-level in the receptacle, the said plug adapted to rest upon the seat partially on its circumference, a discharge-orifice at the smaller end of the divergent cavity for the said outlet-valve, and means for keeping the liquid in the receptacle in contact with the outlet-valve until the opening thereof; as described.

17 In an apparatus for discharging liquids in a vacuum, the combination with a closed vacuum-chamber having an inlet and outlet valve connection, an aperture in the said chamber, a plug-casing exteriorly fixed over the said aperture, the said casing having an inwardly-divergent cavity, a raised seat therein, a float-controlled perforated cylindrical plug adapted for rotary movement in the raised seat, means for discharging the chamber through the plug to the outlet-valve; as described.

18. In an apparatus for discharging liquids in a vacuum, the combination comprising a vacuous receptacle having an inlet connected to the source of liquid and the vacuum, a discharge-valve, a plug-casing disposed upon the exterior of the receptacle, a transversely-disposed partly-cylindrical seat inclosed therein, a cylindrical plug in the seat having a diametrical perforation therethrough, an interiorly-divergent cavity within the said plug-casing on both sides of the plug-seat to the interior of the receptacle and the outlet-valve, a float-connected stem secured in the said plug perforation, means for causing a semirotary movement of the plug by the said stem when actuated by the liquid-level in the receptacle, means for effecting a discharge of the liquid through the stem to the outlet-valve and the atmosphere, and means for opening the said outlet-valve by the hydrostatic head of the liquid when a plenum is established in the receptacle; as described.

19. In an apparatus for discharging liquids under a vacuum, the combination with a vacuous liquid-receiving chamber having an inlet and outlet connection, an angle air and vacuum controlling valve, a detachable cover on the said chamber, an exteriorly-disposed plug-casing connected to the said chamber and outlet-valve, a rotary perforated plug seated centrally within the casing, a hollow discharge-stem fitted at one end to the said plug perforation, a perforated float connected to the other end of the stem, means for discharging the chamber and float through the perforations thereof to the outlet, means for maintaining a channel-way for the liquid to the outlet-valve at any inclination of the said float-stem, means for breaking the vacuum in the chamber during a discharge thereof, and means for automatically restoring the vacuous condition in the chamber after the said discharge; as described.

20. In an apparatus for discharging liquids under a vacuum, the combination with a vacuous receptacle having inlet and outlet connection, an exteriorly-connected flanged partly-cylindrical casing upon the said receptacle, a rotary plug provided with an axial spindle on both sides thereof, centrally located in the said casing, the said plug having a diametrical aperture therethrough, a hollow stem secured in the said aperture, an angular perforated float connected to one end of the stem, an angle vacuum and air valve controlling the passage from the vacuum and the interior of the receptacle, a lever on one of the said plug-spindles, connecting means from the said lever for controlling the said angle-valve by the float; as described.

21. In an apparatus for receiving and discharging liquids under a vacuum, the combination with a normally closed vacuous receptacle having inlet and outlet connection, an outside connected flanged plug-casing having the said outlet-valve thereon, a rotary apertured spindle-provided plug centrally disposed within the said casing, a hollow stem fixed at one end to the plug, a hollow liquid-receiving discharge-float attached to the said stem at a tangent thereof, the said float having perforations placed at an angle and adapted to assume an approximate horizontal position when elevated, an angle-valve connected to the source of vacuum and the interior of the receptacle, an arm on one of the plug-spindles, means for operating the angle-valve by the said arm, and a wheel on the other plug-spindle for manually raising and lowering the float from the exterior of the receptacle; as described.

22. In an apparatus for discharging liquids in a vacuum, the combination with a collecting vacuous chamber having inlet and outlet valves, an outside connected flanged plug-casing, a rotary movable perforated plug having axial spindles on both ends thereof working air-tight in the casing, a series of compression-nut stuffing-boxes on the casing for the said spindles, an angular perforated hollow float, a hollow discharging-stem connected to the said float and plug, a lever on one of the said plug-spindles, an angle-valve controlling the opening to the source of vacuum and the interior of the chamber, an operating-stem for opening and closing the angle-valve connections, a connecting-rod having a perforated offset end at right angles to the rod, means for yieldably connecting the said angle-valve spindle to the said rod and through the offset portion, means for opening the said angle-valve to the vacuum by the said yieldable connection and the connecting-rod, a ratchet-toothed hand-wheel on one of the plug-spindles, a spring-pressed pawl engaging with the teeth of the said wheel, means for operating the float from the exterior of the chamber, means for holding the float and stem with the attached mechanism at any point by the said wheel and pawl, and means for disengaging the float and stem by the pawl and spring thereof through the buoyancy of the inclosed float; as described.

23. In an apparatus for discharging liquids *in vacuo*, the combination with a vacuous receptacle having inlet and outlet connection, an exteriorly-disposed plug-casing attached thereto, a rotary perforated plug having spindles thereon and seated in the said casing, a stem connected at one of its ends to the plug, a hollow float having angular perforations connected to the other end of the stem, an angle combined air-inlet and vacuum cut-off valve for the said receptacle, a partly-threaded working spindle for the angle-valve, an operating-lever on one of the plug-spindles, a connecting-rod having an apertured bracket pivoted to the said lever and resiliently connected to the angle-valve, a spring encompassing the said spindle of the angle-valve below the said bracket, means for opening the receptacle interior to the vacuum against the pressure of the atmosphere by the said spring and connecting-rod, a series of adjusting and locking nuts for regulating the spring compression, a buffer-spring encircling the said angle-valve spindle above the connecting-rod bracket, and means for cushioning the impact of the float upon the bottom of the receptacle by the said buffer-spring; as described.

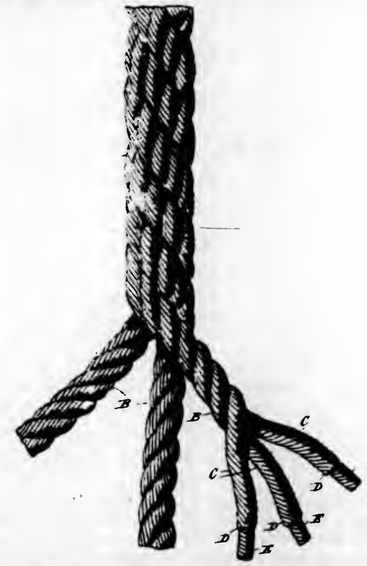
24. In an apparatus for receiving and discharging liquids *in vacuo*, the combination with a vacuous receptacle having inlet and outlet connection for the liquid, an angle snifting-valve comprising a valve-casing provided with a connection to the vacuum and a connection to the interior of the receptacle, a bonnet having an inner hollow cylindrical portion and an outer rounded end perforated air-inlet portion, a partly-threaded stem for float-operating the valve mechanism, a beveled valve-seat, a bevel flanged puppet-valve screw-connected to the inner part of the valve-stem, a threaded sleeve forming a part of the said puppet-valve, an expansible piston movably closing the bore of the hollow cylindrical bonnet portion when the puppet-valve is unseated for communication with the vacuum, a fixed and movable collar on the said puppet-valve sleeve, screw-and-nut means for compressing the collars to expand the piston to fill the bore of the cylindrical or sleeved bonnet portion, connecting-rod-actuated spring means for simultaneously unseating the said puppet-valve against atmospheric pressure and closing the said cylindrical bonnet portion to exclude the atmosphere as described.

25. In an apparatus for discharging liquids *in vacuo*, the combination of a vacuous receptacle having inlet and outlet connection, an angle controlling-valve comprising a valve-casing having connection to the vacuum and the interior of the receptacle at right angles to each other, a partly-threaded valve-stem, a beveled valve-seat in the said valve-casing, a convex-flange winged puppet-valve opening to the said receptacle interior and the vacuum, a threaded sleeve portion on the said puppet-valve, a bearing-collar on the sleeve, an expansible perforated piston encircling the valve-stem, a nut-adjusted collar on the said valve-stem, means for compressing the said piston by the collar, a nut-secured interiorly-sleeved bonnet on the said valve-casing, means for causing a sliding closure of the said sleeve by the piston when the puppet-valve is unseated, a perforated outer portion of the said bonnet, means for drawing air through the said perforations to the interior of the receptacle when the puppet-valve is seated, and spring means for the quick opening of the said puppet-valve against the atmospheric pressure; as described.

26. In an apparatus for discharging liquids *in vacuo*, the combination of a vacuous receptacle having inlet and outlet connection, a controlling-valve comprising a valve-casing, a vacuum connection and a connection to the said receptacle interior, a float-operated stem, a tapering valve-seat, a convex-flanged puppet-valve secured to the said stem, a threaded sleeve on the said puppet-valve, a piston enlargement on the valve-stem, a plug removably fitted to the said valve-casing and provided with a pressure-chamber, a cylindrical bore in the said plug for the piston movement, a balancing cylindrical enlargement on the lower end of the valve-stem and fitting air and steam tight in the plug, a compressed-air and steam inlet in the said plug, means for causing a pressure to enter the receptacle when the puppet-valve is seated for discharging its contents, and means for causing the piston to close the said cylindrical bore when the puppet-valve is open, to exclude the pressure; as described.

27. In an apparatus for discharging liquids *in vacuo*, the combination with a vacuous receptacle having inlet and outlet connection, of an angle control and snifting valve comprising a valve-casing having a vacuum and a receptacle connection, a float-operated spindle, a plug in the said casing having a cylindrical bore and a pressure-chamber, a perforation in the plug for admitting pressure therein and to the receptacle, a beveled flanged puppet-valve normally open to the vacuum, a piston slidably fitting in the said bore, means for simultaneously closing the said puppet-valve and admitting pressure into the receptacle to discharge its contents, means for closing the said bore by the piston when the puppet-valve is open to the vacuum and the interior of the receptacle, means for releasing an excess of pressure in the receptacle, and spring means for resiliently connecting the said puppet-valve, piston and the spindle to the float mechanism; as described.

809,886. ROPE. EDWIN D. METCALF, Auburn, N. Y., assignor to Columbian Rope Company, Auburn, N. Y., a Corporation of New York. Filed Oct. 19, 1905. Serial No. 283,455.



Claim.—1. A rope consisting of strands each twisted about the other and each strand formed of yarns arranged in a core and a sheath therefor, both twisted in the same direction and the core being twisted a greater number of turns than the sheath in a given length of the strand.

2. A cable-laid rope embodying strands, each composed of a core and a sheath formed of yarns, and both core and sheath twisted in the same direction, the core having a greater number of turns than the sheath in an equal length of rope.

3. A rope composed of twisted yarns, the yarns being arranged in cores, and a sheath surrounding each core, said cores and sheaths all being twisted in the same direction but with a greater number of turns in the cores than in the sheaths, to form strands, said strands being twisted about each other and in direction opposite the twists of the strands to form hawser-laid ropes and said ropes being twisted about each other in direction opposite the twists in the hawser-laid ropes to form a cable-laid rope.

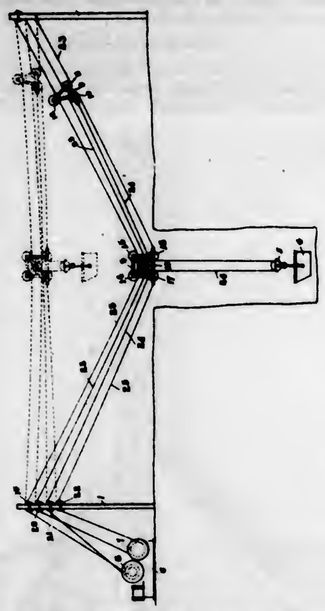
4. The process of making rope-strands which consists in twisting a bundle of yarns to form a core then applying a sheath of yarns to the twisted core and twisting said core and sheath in the same direction, whereby the twists in the core and sheath will be in the same direction but with a greater number of turns in the core.

809,387. CABLEWAY. THOMAS S. MILLER, South Orange, N. J. Filed Dec. 16, 1902. Serial No. 135,943.

Claim.—1. In a ropeway in combination, a carriage-supporting rope, a load-carriage supported therefrom, a hoisting-rope having a loop pendent from the load-carriage and extending therefrom toward the head and tail, a traction-rope having a loop extending toward the tail-support, a movable block to which one end of the hoisting-rope is secured, and a winding mechanism controlling the other end of said hoisting-rope, said movable block forming a connection between the loop of the traction-rope and the main rope.

2. In a ropeway, in combination, two winding mechanisms having independent clutches and brakes, a traction-rope connected with

one, a load-carriage having both a traction and a supporting engagement with said traction-rope, two ropes connected with the other winding mechanism, one being the hoisting-rope and the other controlling the deflection of said traction-rope.



3. In a ropeway, in combination, a load-carriage, a rope participating both in its traction and support, a movable pulley in a loop of said rope, winding mechanism, a rope whereby the tension of said winding mechanism is applied to said movable pulley and a hoisting-rope extending from the same winding mechanism to the fall.

4. In a ropeway, in combination, a load-carriage, a rope participating both in its traction and support, a movable pulley in a loop of said rope, winding mechanism, a rope whereby the tension of said winding mechanism is applied to said movable pulley, and a hoisting-rope extending from the same winding mechanism over load-carriage sheaves and forming a loop at the fall.

5. In a ropeway, in combination, a load-carriage, a rope participating both in its traction and support, a movable pulley in a loop of said rope, winding mechanism, a rope whereby the tension of said said winding mechanism is applied to said movable pulley and a hoisting-rope extending from the same winding mechanism to the same movable pulley and forming a loop at the fall.

6. In a ropeway, in combination, a main rope, a traction-rope, means for controlling the deflection of the same, means whereby the deflection is automatically transmitted from one to the other, a load-carriage containing a running supporting engagement with said main rope and with one run of said traction-rope and a traction engagement with the other run of said traction-rope and a hoisting-rope having a running connection with said carriage and extending thence toward the head and tail.

7. In a ropeway, in combination, a load-carriage, ropes supporting the same, means whereby the deflection of the same is controlled, a winding mechanism and a hoisting-rope having one end connected with said winding mechanism and the other end with said supporting-ropes.

8. In a ropeway, in combination, a load-carriage, a traction-rope containing a loop at the tail end, a main rope extending between the head and tail supports, and a movable sheave-block extending between the loop and the main rope and coupling said loop with said main rope.

9. In a ropeway, in combination, a load-carriage, ropes whereby it is supported, a fall-rope and operatively-connected means whereby the deflection of said supporting-ropes and the length of the fall are correlatively controlled.

10. In a ropeway, in combination, a load-carriage, ropes whereby it is supported, a hoisting-rope, a prime mover and means whereby the deflection of all of said ropes is correlatively controlled by the power of said prime mover.

11. In a ropeway, in combination, a load-carriage, a hoisting-rope and means whereby the deflection of said hoisting-rope and the length of the fall are concurrently controlled.

12. In a ropeway, in combination, a load-carriage, ropes by which it is supported, a fall and means whereby said supporting and fall ropes are concurrently moved at a differential speed to control the deflection of the supporting-ropes and the length of the fall.

13. In a ropeway, in combination, a load-carriage, ropes by which it is supported, a fall and means whereby the elevation of the load is controlled by a concurrence of ropeway deflection and the length of fall-rope movements.

14. In a ropeway, in combination, a load-carriage, ropes by which it is supported, an actuator whereby the deflection of said ropes is controlled; the maximum power of said actuator being less than that which will produce a breaking strain on said ropes.

15. In a ropeway, in combination, a load-carriage, two drums, a rope operated by each of said drums participating in the support of said carriage and a fall-rope operated by one of said drums.

16. In a ropeway, in combination, a load-carriage, a fall-block, ropes by which said load-carriage is supported, a fall-rope and a rope-drum by which both the elevation of the load-carriage and the length of the fall are concurrently controlled.

17. In a ropeway, in combination, a load-carriage, a fall-block, ropes whereby the load-carriage is supported and traversed, a fall-rope and two rope-drums one of which controls the traverse and the other of which concurrently controls both the elevation of the load-carriage and the length of the fall.

18. In a ropeway, in combination, a load-carriage, ropes by which it is supported, a hoisting-rope, operatively-connected means whereby the deflection of said supporting-ropes and the length of fall are concurrently controlled and means whereby the speed of operating said supporting-ropes is reduced below that of operating said hoisting-rope.

19. In a ropeway, in combination, a load-carriage, a hoisting-rope having a loop suspended from the carriage and extending thence toward the head and tail, winding mechanism for one end of said hoisting-rope, a rope-support for the other and thereof between the head and tail of the ropeway, means whereby the position of said rope-support may be controlled and means whereby the deflection of said ropeway may be controlled.

20. In a ropeway, in combination, a load-carriage, two drums one of which contains parts of different diameters, a rope operated by each of said drums participating in the support of said carriage and a fall-rope operated by one of said drums at a different diameter.

21. In a ropeway, in combination, a load-carriage, a rope-drum containing parts of different diameters, a carriage-supporting rope operated at one diameter of said drum and a fall-rope operated by the other diameter thereof.

22. In a ropeway, in combination, a load-carriage, a rope-drum, a carriage-supporting rope operated by said drum and a fall-rope also operated by said drum.

809,388. CONVERTIBLE WAGON-BOX AND HAY-RACK. GEORGE B. MILLS, South Bend, Ind. Filed May 9, 1905. Serial No. 259,879.

Claim.—1. A bed-frame including sills and cross-bars, an end-gate permanently supported upon the front cross-bar, an end-gate hingedly connected with the rear cross-bar, side members hingedly connected with the sills, a shaft journaled longitudinally in the bed-frame, drums upon said shafts, and flexible supporting means connected with said drums and guided to the upper corners of the hinged side members over guide means including pulleys upon the lower corners of the end-gates and pulleys upon the inner sides of the end sills.

2. A bed-frame including sills and cross-pieces, hinge-leaves upon the outer sides of the sills, side members, hinge-leaves upon the inner sides of said side members, and hinge members each including a pair of parallel pintles and a cross-bar connecting the same and constituting a link.

3. A bed-frame including sills and cross-bars, side members supported in an upright position upon the upper edges of the sills and connected with the latter by hinges including links, and angular brace members upon the side members adapted to abut upon the outer sides of the sills when the side members are extended.

4. A bed-frame including sills and cross-bars, side members supported in an upright position upon the upper edges of the sills and connected with the latter by hinges including links, angular brace members upon the side members adapted to abut upon the outer sides of the sills when the side members are extended, flexible supporting means connected with the upper corners of the side members, and winding-drums for said flexible supporting means.

5. In a device of the class described, the combination with a bed-frame including sills, of side members including stakes, angular brace members at the lower ends of said stakes, and brace-rods connecting the outer ends of said angular braces with the upper ends of the stakes; and means for hingedly connecting said sills and side members.

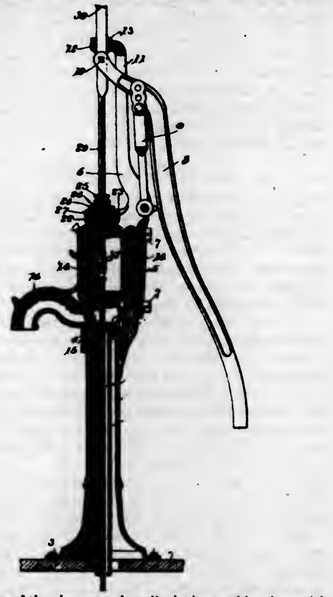
6. In a device of the class described, the combination with a bed-frame including sills, of side members including stakes, angular box-like brace members at the lower ends of said stakes having recesses in their under sides near their outer ends, and brace-rods having heads seated in said recesses the upper ends of said brace-rods being connected with the upper ends of the stakes; and means for hingedly connecting said sills and side members.

7. In a device of the class described, a bed-frame, front and rear end-gates, side members connected hingedly with the sills of the bed-frame, a boom-ladder supported slidingly upon the front end-gate, and a post supported slidingly upon the rear end-gate and having a loop at its upper end; in combination with flexible supporting means for the hinged side members, winding-drums for said flexible supporting means, and means for retaining said winding-drums at various adjustments.

809,389. PUMP. PHILIP A. MYERS, Ashland, Ohio, assignor to F. E. Myers and Brother, Ashland, Ohio, a Copartnership. Filed June 13, 1905. Serial No. 264,782.

Claim.—1. A pump comprising a standard, a fulcrum-support detachably connected therewith and having a supporting-ring, a reservoir-head removably supported at its lower end on the standard and having at its upper end a reduced portion or neck to fit within said ring, and a stuffing-box carried by said neck and having a diameter less than the internal diameter of the ring, a pipe detachably connected to the lower end of the reservoir-head, and a pump-rod comprising two separable sections, the upper section being unitary and comprising a lower part circular in cross-section, fitting the stuffing-box, and adapted for connection with the lower section of the pump-rod, and an upper part in the form of a flattened bar of a maximum diameter greater than the lower part, fitting the guide, and adapted for connection with the windmill, and a pump-handle carried by said fulcrum-support, substantially as described.

2. A pump comprising a standard, a fulcrum-support detachably connected therewith and having a supporting-ring and pump-rod guide, a reservoir-head removably supported at its lower end on the standard and having at its upper end a reduced portion or neck to fit within said ring, and a stuffing-box carried by said neck and having a diameter less than the internal diameter of the ring, a pipe detachably connected to the lower end of the reservoir-head, and a pump-rod comprising two separable sections, the upper section being unitary and comprising a lower part circular in cross-section, fitting the stuffing-box, and adapted for connection with the lower section of the pump-rod, and an upper part in the form of a flattened bar of a maximum diameter greater than the lower part, fitting the guide, and adapted for connection with the windmill, and a pump-handle carried by said fulcrum-support, substantially as described.



3. In a pump of the character described, the combination, with a standard having a supporting-seat at the upper end of its body, of a fulcrum-support detachably connected with said standard and provided with a supporting-ring, a reservoir-head supported vertically in the standard-seat at its lower end and having a reduced neck at its upper end which fits and is laterally supported by the ring, said neck carrying a stuffing-box, of a diameter such as to pass freely through said ring, substantially as described.

4. In a pump of the character described, the combination, with a standard and a reservoir-head removably supported thereon and provided with a stuffing-box, of a detachable fulcrum-support having a ring fitting over the upper end of the reservoir-head and its stuffing-box, said ring being of greater diameter than the upper end of the reservoir-head and stuffing-box, so as to be freely removable by an upward motion relatively thereto, and a pump-rod section having a round lower part adapted to pass through the stuffing-box, and a flattened upper part, the maximum diameter of which is greater than that of the lower part, substantially as described.

5. In a pump of the character described, the combination, with a reservoir-head internally threaded at its lower end, of a bushing externally threaded to fit the internal thread of the reservoir-head, and having a passage therethrough with threaded portions of different diameters, substantially as described.

809,390. PULLEY-MOUNTING. WILLIAM T. MCDERMOTT and WILLIAM P. BUTZEL, Baltimore, Md. Filed Jan. 11, 1905. Serial No. 240,883.

Claim.—1. In a pulley-mounting, the combination with a retaining-plate to be secured to a window-frame or analogous support, said plate having an opening, of a pulley-support having portions that engage both the inner and outer sides of the plate, a part of the support extending through the opening and said support being removable outwardly through said opening, a pulley journaled on the

support, and means on the outside of the plate for detachably securing the support against movement to the retaining-plate, said securing means thus being accessible when the plate is secured to a window-frame to permit the removal of the pulley-support and the pulley carried thereby.

2. In a pulley-mounting, the combination with a retaining-plate to be secured to a window-frame or analogous support and having an opening, of a pulley-boxing fitting in the opening and having a face-plate that engages both the inner and outer sides of the retaining-plate, said boxing being removable outwardly through the opening a pulley journaled in the boxing, means for detachably fastening the boxing to the outer side of the retaining-plate, said means being accessible when the plate is secured to a window-frame to permit the detachment of the boxing and pulley carried thereby and means for fastening the retaining-plate to a support.

3. In a pulley-mounting, the combination with a retaining-plate to be secured to a window-frame or analogous support, said plate having a seat in its outer face and an opening that communicates with said seat, of a pulley-support that passes through the opening, said support having a face-plate that fits in the seat, a tongue carried by the face-plate and engaging the rear face of the retaining-plate, means for securing the retaining-plate to a frame or other support, means for detachably securing the face-plate in the seat, and a pulley journaled in the support.

4. In a pulley-mounting, the combination with a retaining-plate having a seat in its inner side and an opening located at one end of the seat, of a pulley-support that passes through the opening, said support engaging over the front face of the plate and being provided with a tongue that passes through the opening and engages in the rear seat, means for securing the retaining-plate to a frame or other support, means passing through the face-plate and engaging the retaining-plate for detachably securing the pulley support in place, and a pulley journaled in the support.

5. In a pulley-mounting, the combination with a retaining-plate to be secured to a window-frame, said plate having a longitudinally-disposed opening, a seat in its front face that substantially surrounds the opening, and a seat in its rear face located at one end of the opening, of means for fastening the retaining-plate to the frame, a face-plate that fits in the front seat of the retaining-plate, a tongue carried by one end of the face-plate, passing through the opening, and engaging in the rear seat, a screw passing through the other end of the face-plate and engaging the retaining-plate for holding said face-plate in position, a boxing carried by the rear side of the face-plate and passing through the opening in the retaining-plate, and a pulley journaled in the boxing.

6. In a pulley-mounting, the combination with a window-frame wall having an opening, of a retaining-plate secured thereto and having an opening alined with the wall-opening, a pulley-boxing passing through the plate-opening and having a tongue engaging the rear portion of said plate, said boxing also having a portion located over the front face of the plate, holding means passing through said latter portion, and a pulley in the boxing.

7. In a pulley-mounting, the combination with a frame-wall having an opening, of a retaining-plate secured to the rear face of the frame-wall, said plate having an opening alined with the wall-opening and a seat in its outer side, a flange carried by the frame-wall and engaging in the seat, a pulley-boxing passing through the plate-opening and having a tongue engaging the rear portion of the plate, a face-plate carrying the boxing and fitting in the seat of the retaining-plate alongside the flange, a pulley located in the boxing, and means for detachably fastening the face-plate to the retaining-plate.

8. In a pulley-mounting, the combination with a metallic frame-wall having an opening and rearwardly-extending flanges surrounding the said opening, of a retaining-plate secured to the rear face of the wall and having a seat that receives the flanges, said retaining-plate being also provided with an opening, a face-plate fitting snugly in the seat within the flanges, means for detachably securing said plate in place, a pulley-support carried by the face-plate and extending through the opening in the retaining-plate, and a pulley journaled on the support.

809,891. TYPE-WRITING MACHINE. LOUIS C. HERY, New York, N. Y. Filed Mar. 14, 1904. Serial No. 198,068.

Claim.—1. In a type-writing machine, a carriage-feed mechanism comprising a carriage-controlling mechanism, a vibratory member, a detaining member and a rotary spacing member carried thereby, the axis of said spacing member being substantially at right angles to the contact-face thereof, means whereby pressure from the engagement of the carriage-controlling mechanism with said spacing member during the direct movement of said vibratory member holds said spacing member stationary and said spacing member is permitted to rotate instantly upon the initial reversal of movement of said vibratory member, such rotation of said spacing member permitting axial movement thereof, means whereby said spacing member is restored to its normal position after each spacing and connections between said vibratory member and the several key-levers whereby said detaining member and said spacing member are caused to successively engage said carriage-controlling mechanism.

2. In a type-writing machine, a carriage-feed mechanism comprising a carriage-controlling mechanism, a vibratory member, a detaining member and a rotary spacing member consisting of a flange and an axle or shaft therefor extending at substantially right angles to the contact-face thereof, carried by said vibratory member, opposed bearings carried respectively by said vibratory member and said shaft whereby pressure from the engagement of the carriage-controlling mechanism with said spacing member during the direct movement of said vibratory member, holds said spacing member stationary, and said spacing member is permitted to rotate instantly upon the initial reversal of movement of said vibratory member, such rotation of said spacing member permitting axial movement thereof, a spring whereby said spacing member is restored to its normal position after each spacing, and connections between said vibratory member and the several key-levers whereby said detaining member and said spacing member are caused to successively engage said carriage-controlling mechanism.

3. In a type-writing machine, a carriage-feed mechanism comprising a carriage-controlling mechanism, a vibratory member, a detaining member and a rotary spacing member consisting of a flange and an axle or shaft therefor extending at substantially right angles to the contact-face thereof, carried by said vibratory member, opposed bearings carried respectively by said vibratory member and said shaft whereby pressure from the engagement of the carriage-controlling mechanism with said spacing member, during the direct movement of said vibratory member, holds said spacing member stationary, and said spacing member is permitted to rotate instantly upon the initial reversal of movement of said vibratory member, said rotation of said spacing member permitting axial movement thereof, means whereby the axial movement of said spacing member is limited to a portion of a letter-space, a spring whereby said spacing member is restored to its normal position after each spacing, and connections between said vibratory member and the several key-levers whereby said detaining member and said spacing member are caused to successively engage said carriage-controlling mechanism.

4. In a type-writing machine, a carriage-feed mechanism comprising a carriage-controlling mechanism, a vibratory member, a detaining member and a rotary spacing member consisting of a flange and an axle or shaft therefor extending at substantially right angles to the contact-face thereof, carried by said vibratory member, opposed bearings carried by said vibratory member and said shaft respectively whereby pressure from the engagement of the carriage-controlling mechanism with said spacing member during the direct movement of said vibratory member holds said spacing member stationary and said spacing member is permitted to rotate instantly upon the initial reversal of movement of said vibratory member, such rotation of said spacing member permitting axial movement thereof, a spring adapted to rotate said shaft whereby said spacing member is restored to its normal position after each spacing and said opposed bearings are forced into intimate contact with each other, and connections between said vibratory member and the several key-levers whereby said detaining member and said spacing member are caused to successively engage said carriage-controlling mechanism.

5. In a type-writing machine, a carriage-feed mechanism comprising a carriage-controlling mechanism, a vibratory member, a detaining member and a rotary spacing member consisting of a flange and an axle or shaft therefor extending at substantially right angles to the contact-face thereof, carried by said vibratory member, opposed bearings carried respectively by said vibratory member and said shaft whereby pressure from the engagement of the carriage-controlling mechanism with said spacing member during the direct movement of said vibratory member, holds the spacing member stationary, and said spacing member is permitted to rotate instantly upon the initial reversal of movement of said vibratory member, such rotation permitting axial movement thereof, a spring whereby said spacing member is restored to its normal position after each spacing, said carriage-controlling mechanism comprising a rack member, the teeth of which present contact-faces to said spacing member on different planes whereby engagement of said parts will be at different radii during the printing and the spacing intervals, and connections between said vibratory member and the several key-levers, whereby said detaining member and said spacing member are caused to successively engage said carriage-controlling-mechanism rack member.

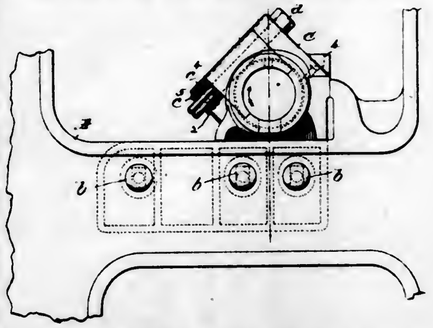
6. In a type-writing machine, a carriage-feed mechanism comprising a carriage-controlling mechanism, a vibratory member, a yoke carried thereby having oppositely-disposed bearings therein, a detaining member mounted on said vibratory member, a spacing member comprising a flange and an axle or shaft having a winding way therein mounted in said bearings and extending at substantially right angles to the contact-face of said flange, a guide carried by said yoke and engaging said way whereby pressure from the engagement of the carriage-controlling mechanism with said spacing member during the direct movement of said vibratory member holds said spacing member stationary, and said spacing member is permitted to rotate instantly upon the initial reversal of movement of said vibratory member, such rotation of said spacing member permitting axial movement thereof, a spring whereby said spacing member is restored to its normal position after each spacing, and connections between said vibratory member and the several key-levers whereby said detaining member and said spacing member are caused to successively engage said carriage-controlling mechanism.

7. In a type-writing machine, a carriage-feed mechanism comprising a carriage-controlling mechanism, a vibratory member, a yoke carried thereby having oppositely-disposed bearings therein, a detaining member mounted on said vibratory member, a spacing member comprising a flange and an axle or shaft therefor having a winding way therein, mounted in said bearings and extending at substantially right angles to the contact-face of said flange, a guide comprising a screw-threaded point-bearing carried by said yoke and engaging said way whereby pressure from the engagement of the carriage-controlling mechanism with said spacing member during the direct movement of said vibratory member holds said spacing member stationary, and said spacing member is permitted to rotate instantly upon the initial reversal of movement of said vibratory member, such rotation of said spacing member permitting axial movement thereof, a spring whereby said spacing member is restored to its normal position after each spacing, and connections between said vibratory member and the several key-levers, whereby said detaining member and said spacing member are caused to successively engage said carriage-controlling mechanism.

8. In a type-writing machine, a carriage-feed mechanism comprising a carriage-controlling mechanism, a vibratory member, a yoke carried thereby having oppositely-disposed bearings therein, a detaining member mounted on said vibratory member, a spacing member comprising a flange and an axle or shaft having a winding way therein mounted in said bearings and extending at substantially right angles to the contact-face of said flange, a guide carried by said yoke engaging said way whereby pressure from the engagement of said carriage-controlling mechanism with said spacing member during the direct movement of said vibratory member holds said spacing member stationary and said spacing member is permitted to rotate instantly upon the initial reversal of movement of said vibratory member, such rotation of said spacing member permitting axial movement thereof, means whereby axial movement of said spacing member is limited to a portion of a letter-space, a spring whereby said spacing member is restored to its normal position after each spacing, and connections between said vibratory member and the several key-levers whereby said detaining member and said spacing member are caused to successively engage said carriage-controlling mechanism.

9. In a type-writing machine, a carriage-feed mechanism comprising a carriage-controlling mechanism, a vibratory member, a detaining member and a rotary spacing member consisting of a flange and an axle or shaft therefor extending at substantially right angles to the contact-face thereof, carried by said vibratory member, opposed bearings carried respectively by said vibratory member and said shaft whereby pressure from the engagement of the carriage-controlling mechanism with said spacing member during the direct movement of said vibratory member holds said spacing member stationary, and said spacing member is permitted to rotate instantly upon the initial reversal of movement of said vibratory member, such rotation of said spacing member permitting axial movement thereof, a spring whereby said spacing member is restored to its normal position after each spacing and connections between said vibratory member and the several key-levers whereby said detaining member and said spacing member are caused to successively engage said carriage-controlling mechanism, said detaining member being provided with an extension alined with and following the top periphery of said spacing member.

809,892. CRANK-SHAFT SUPPORT FOR LOOMS. ANTHONY J. O'REILLY, Worcester, Mass., assignor to Crompton-Thayer Loom Company, Worcester, Mass. Filed June 13, 1904. Serial No. 212,300.



Claim.—1. The combination with a crank-shaft, of a box having two arms, one of said arms crossing a vertical plane passing through the longitudinal axis of said crank-shaft, said arms being provided with holes extending in alinement transversely of the crank-shaft, a cap disposed between the two arms, and a bolt passing through the cap and entering the alined holes in the said arms.

2. A crank-shaft bearing comprising a box having two arms, said arms being extended to one side of a vertical plane passing through the longitudinal axis of said bearing, a cap disposed between the two arms, and a single bolt passing transversely of the bearing through said arms and holding the cap in place between the extended arms.

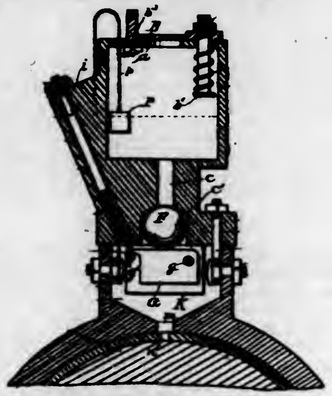
3. A bearing comprising a box having two arms, the uppermost one of which is extended across a vertical line intersecting the longitudinal axis of said shaft, a cap entering the space between said arms, said cap being bored through from one to its opposite edge and a bolt extended through the hole in said cap and also through the hole in that one of said arms that crosses a vertical line intersecting the longitudinal axis of said shaft, the opposite end of said bolt being extended through the lowermost arm of said box, the bolt retaining the cap in working position.

809,893. LUBRICATOR. WILLIAM S. PATTERSON, Salt Lake City, Utah. Filed Mar. 3, 1905. Serial No. 248,280.

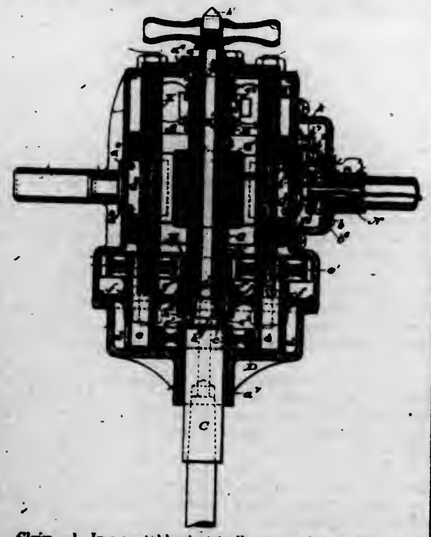
Claim.—1. A lubricator whose oil-cup, neck, base, adjuster-housing and lugs on the lower side of said base are integral, an adjustable lever journaled in said lugs, an intake for the oil and an adjustable cover therefor as described.

2. A lubricator comprising an oil-cup, provided with an oil-inlet in its top, an oil-channel extending downward from said cup and opening into a chamber, a ball-valve in said chamber to close said channel, and an adjustable lever to support and vertically move said ball for the purpose specified.

3. A lubricator comprising an oil-cup provided with an oil-inlet, an oil-channel extending downward from said cup and opening into a chamber, a ball-valve in said chamber to close said channel, a lever to support said ball-valve, there being a finger on said lever, a spring engaged by said finger, an adjusting-bolt attached to said spring, there being a housing exterior to the oil-cup (in which said bolt is longitudinally movable) provided with teeth on its upper surface, and a nut on said bolt having notches to engage said teeth as described.



809,394. ELECTRICALLY-OPERATED PORTABLE DRILL. ADOLPH PFLUMMER, Cleveland, Ohio, assignor to The Van Dorn-Elliott Electric Co., Cleveland, Ohio, a Corporation of Ohio. Filed Sept. 19, 1904. Serial No. 224,963.



Claim.—1. In a portable electrically-operated drill, the combination of a multipolar motor provided with a casing and a hollow shaft; a drill-spindle mounted in said casing; intermediate gearing connecting said motor-shaft and spindle; and a feed-screw located within said hollow shaft and provided with an end portion projecting therefrom and having a bearing adapted to receive the inner end of said drill-spindle.

2. In a portable electrically-operated drill, the combination of a multipolar motor provided with a casing and mounted within the latter and having a hollow shaft; a feed-screw mounted within said shaft and coaxial therewith; a drill-spindle mounted in one end of the casing and having its axis in the same straight line with the motor's axis; a removable head secured to the other end of said casing; intermediate gearing connecting said motor and spindle; a diaphragm located transversely of said line of the motor-axis, one end of said diaphragm; and binding-bolts passing through said head between the separate field-sections and having their inner ends secured to said diaphragm.

3. In a portable electrically-operated drill, the combination of a multipolar motor provided with a casing and mounted within the latter and having a hollow shaft; a feed-screw mounted within and coaxial with said shaft; a drill-spindle mounted in one end of the casing and having its axis in the same straight line with the motor's axis; a removable head secured to the other end of said casing; intermediate gearing connecting said motor and spindle; a diaphragm located transversely of said line of the motor-axis, one end of said shaft being supported by said head and the other by said diaphragm; binding-bolts passing through said head and between the separate field-sections and having their inner ends secured to said diaphragm; and a controller for said motor having its resistance-coils mounted upon said binding-bolts.

4. In a portable electrically-operated drill, the combination of a multipolar motor provided with a casing and a shaft; a drill-spindle mounted in said casing; a removable head secured to said casing, provided with a bearing for one end of the motor-shaft, and including an annular ring adjustable around the axis of the motor-shaft; brush-holders mounted upon said ring; intermediate gearing connecting said motor and spindle; a diaphragm located transversely of the motor-shaft and providing a bearing for the other end of the latter; and binding-bolts passing through said head between the separate field-sections and having their inner ends secured to said diaphragm.

5. In a portable electrically-operated drill, the combination of a motor provided with a casing and a shaft; a drill-spindle mounted in said casing; gearing connecting said motor-shaft and drill-spindle; and a feed-screw located within said casing centrally relatively to said motor and arranged with one end in juxtaposition to the inner end of said drill-spindle.

809,395. LOCK FOR CROSSED WIRES. ELMER T. POCKLINGTON, Clayton, Mich. Filed Jan. 6, 1905. Serial No. 239,954.

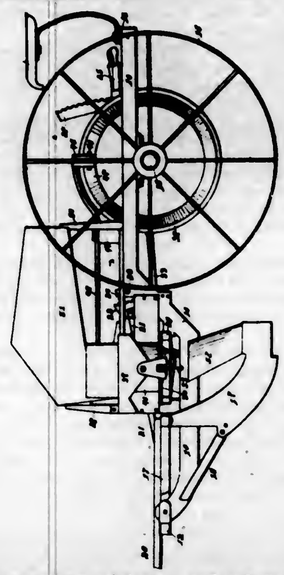
Claim.—1. The combination with a pair of crossed wires, of a substantially U-shaped lock therefor having its bend straddling one of the wires with its sides substantially parallel therewith and crossing the other wire at the opposite side of the first wire, the end portion of one of the sides of the lock being bent transversely across the first-mentioned wire upon the same side thereof as the original bend of the lock and engaged with the other side of the lock, the end of said other side of the lock being bent transversely across the adjacent side of the first-mentioned wire and hooked around the same.

2. The combination with a pair of crossed wires, of a substantially U-shaped lock having its bend placed astraddle of one of the wires with its sides extending across the other wire at the opposite side of the first-mentioned wire, one side of the lock lying entirely upon one side of the first-mentioned wire with its extremity hooked about the same, and the other side of the lock bent transversely across the first-mentioned wire and engaged with the first-mentioned side of the lock.

3. The combination with a pair of crossed wires, of a substantially U-shaped lock having its bend straddling one of the wires with its sides crossing the other wire at the opposite side of the first-mentioned wire, the sides of the lock being bent inwardly across the adjacent wire upon opposite sides thereof, one side of the lock being hooked about the adjacent wire and the other side being hooked about the first-mentioned side of the lock at the opposite side of the wire.

809,396. AUTOMATIC POTATO CUTTER AND PLANTER. JOHN J. PUTNEY, Stuart, Iowa. Filed Feb. 20, 1905. Serial No. 247,044.

Claim.—1. In a potato cutter and planter, a carriage-frame composed of rigid parallel side pieces and cross-pieces mounted upon a rotatable axle, a runner-frame hinged to its front end, a pole fixed to the runner-frame, an arm fixed to the rear end of the pole, a toothed sector fixed to the rear end of the arm, a rotatable shaft mounted on the carriage-frame, a hand-lever fixed to the end of the shaft, a rack fixed to the side of the frame and a pawl carried by the hand-lever to engage the rack, arranged and combined to operate in the manner set forth, for the purposes stated.



2. In a potato cutter and planter, a carriage-frame composed of rigid parallel side pieces and cross-pieces mounted upon a rotatable axle, a runner-frame hinged to its front end, a pole fixed to the runner-frame, an arm fixed to the rear end of the pole, a toothed sector fixed to the rear end of the arm, a rotatable shaft mounted on the carriage-frame, a gear-wheel on said shaft and means for actuating the shaft, standards fixed to the carriage-frame and a hopper having an inclined bottom fixed to the standards, arranged and combined to operate in the manner set forth for the purposes stated.

3. In a potato cutter and planter, a carriage-frame composed of rigid parallel side pieces and cross-pieces mounted upon a rotatable axle, a runner-frame hinged to its front end, a pole fixed to the runner-frame, an arm fixed to the rear end of the pole a toothed sector fixed to the rear end of the arm, a rotatable shaft mounted on the carriage-frame, a gear-wheel on said shaft and means for actuating the shaft, standards fixed to the sides of the carriage-frame, a hopper having an inclined bottom fixed to the standards and platforms fixed to the sides of the carriage-frame to extend outward from the standards, arranged and combined to operate in the manner set forth for the purposes stated.

4. In a potato cutter and planter, a horizontal reciprocating cutter-carrier having fixed cutters, a grooved cam-wheel on a rotatable axle, a lever pivoted to the carriage-frame and the short arm of the lever extended into the cam and the long arm slidably and pivotally connected with the cutter-carrier, arranged and combined to operate in the manner set forth for the purposes stated.

5. In a potato cutter and planter, a horizontal reciprocating cutter-carrier having fixed cutters, a grooved cam-wheel on a rotatable axle, a lever pivoted to the carriage-frame and the short arm of the lever extended into the cam and the long arm slidably and pivotally connected with the cutter-carrier, and plates fixed to the end portions of the cutter-carrier to retain potatoes in position to be engaged by the fixed cutters on the end portions of the said carrier, arranged and combined to operate in the manner set forth for the purposes stated.

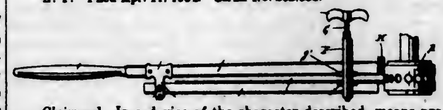
6. In a potato cutter and planter, a horizontal reciprocating cutter-carrier having fixed cutters, a grooved cam-wheel on a rotatable axle, a lever pivoted to the carriage-frame and the short arm of the lever extended into the cam and the long arm slidably and pivotally connected with the cutter-carrier, plates fixed to the end portions of the cutter-carrier to retain potatoes in position to be engaged by the fixed cutters on the end portions of the said carrier and platforms having open-ended potato-conveyers fixed above the said potato-cutters, arranged and combined to operate in the manner set forth for the purposes stated.

7. In a potato cutter and planter, a horizontal reciprocating cutter-carrier having fixed cutters, a grooved cam-wheel on a rotatable axle, a lever pivoted to the carriage-frame and the short arm of the lever extended into the cam and the long arm slidably and pivotally connected with the cutter-carrier, plates fixed to the end portions of the cutter-carrier to retain potatoes in position to be engaged by the fixed cutters on the end portions of the said carrier, platforms having open-ended potato-conveyers fixed above the said fixed potato-cutters, arranged and combined to operate in the manner set forth for the purposes stated.

8. In a potato cutter and planter, a horizontal reciprocating cutter-carrier having fixed cutters, a grooved cam-wheel on a rotatable axle, a lever pivoted to the carriage-frame and the short arm of the lever extended into the cam and the long arm slidably and pivotally connected with the cutter-carrier, plates fixed to the end portions of the cutter-carrier to retain potatoes in position to be engaged by the fixed cutters on the end portions of the said carrier, platforms having open-ended potato-conveyers fixed above the said fixed potato-cutters, a reciprocating potato-carrier mounted on top of said platform and means for actuating said potato-carrier and a hopper above the said potato-carrier for feeding potatoes to said potato-carrier, arranged and combined to operate in the manner set forth for the purposes stated.

9. In a potato cutter and planter, a reciprocating potato-carrier, a cam-wheel fixed to the rotatable axle of a carriage, a lever pivotally connected with the carriage-frame and its front end connected with the reciprocating potato-carrier and its rear end provided with a cross-head and rollers journaled to the end of the cross-head to engage cam-surfaces at the sides of the cam-wheel, arranged and combined to operate in the manner set forth for the purposes stated.

809,397. SPOKE-EXTRACTOR. GEORGE RAITHEL, Middleville, N. Y. Filed Apr. 11, 1904. Serial No. 202,533.



Claim.—1. In a device of the character described, means provided to clutch a spoke, said means provided with an outwardly-extended handle and a block adapted to provide a fulcrum for the handle in its operation to and fro across the normal line of the spoke, substantially as described.

2. In a spoke-extractor, clutching means comprising two bars adjustably pivotally connected toward their outer end and adjustably connected at their inner end, adjustable means provided between the end of the bars and the hub for applying side movement of the bars in extracting the spoke, in combination, substantially as shown.

3. In a device of the character described, a member provided with means to clutch a spoke and extended substantially parallel with the spoke and adapted to receive and transmit an increased leverage applied thereto crosswise of the spoke and a block adapted to provide a fulcrum for the said member, in swinging it to and fro across the normal line of the spoke.

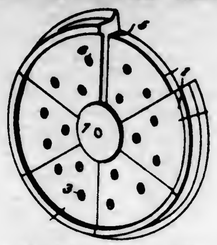
4. In a device of the character described, a member having means adjustable to clamp a spoke and being adapted to receive and apply to the spoke increased leverage applied to the said member beyond the end and transverse the line of said spoke and a hand-block adapted to be placed between the hub and the said clamping member, for applying side movement of the member in extracting the spoke.

5. In a device of the character described, a member adapted to clutch various sizes of spokes lengthwise thereof and secure an extended leverage for the application of side pressure to the spoke and a fulcrum-block adapted to provide a fulcrum for the said member in swinging to and fro in extracting the spoke.

6. In a device of the character described, a member adapted to clutch various sizes of spokes lengthwise thereof and extending beyond the end of the spoke to transmit side pressure to the spoke and a hand-block adapted to be placed on alternate sides of the spoke between the clutching member and the hub to provide a fulcrum for the clutching member in swinging it to and fro to withdraw the spoke.

7. In a spoke-extractor, a clamp and a key, the former being adapted to extend beyond the spoke for use of high leverage in applying reciprocating lateral pressure to the spoke and the latter being adapted to be inserted between the clamp and the hub to employ said pressure in extracting the spoke, substantially as described.

809,398. SECTIONAL CAR-WHEEL. GEORGE W. RICHARDS, Mountaintop, Pa. Filed Apr. 14, 1905. Serial No. 255,562.



Claim.—1. A car-wheel comprising a body, a sectional tread composed of a plurality of segments, each segment embodying an extension overlapping the body at one side thereof, a plate removably secured centrally of the side of the body upon which the extensions of the segments aforesaid are arranged, engaging the inner ends of the extensions to coact therewith to prevent displacement of the same, and means at the outer portion of the body of the wheel for fastening the outer portions of the segments thereto.

2. A car-wheel comprising a body and a sectional tread, the tread-sections having extensions overlapping the body, and a plate attached to the body and interlocking with the extensions aforesaid.

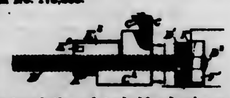
3. A sectional car-wheel comprising a body and a sectional tread, the tread-sections having shoulders interlocking with the outer edge of said body, extensions projected from the tread-sections, and a plate removably attached to a side of the body centrally thereof and interlocking with the extensions of the tread-sections.

4. A car-wheel comprising a body, a sectional tread composed of a plurality of segments, each segment embodying an extension overlapping the body at one side thereof, a threaded extension projected from the central portion of the body, a plate secured to said extension, said plate being disposed at the side of the body upon which the extensions of the segments are arranged and engaging the inner ends of said extensions to coact to prevent displacement thereof, and means at the outer portion of the body of the wheel for fastening the outer portions of the segments thereto.

5. In a sectional car-wheel, the combination of a disk having a raised seat on one side thereof, a sectional tread having a shoulder adapted to fit against the edge of said disk and having a flange extending along one face of the disk and bearing against the sides of said raised seat and having recesses therein, a plate fitting over said raised seat and extending over said flanges and having a projection to engage in the before-mentioned recesses in the flanges to prevent radial movement of the sections, and means for securing the disk and tread-sections together.

6. In a sectional car-wheel the combination of a disk having beveled edges and a raised seat on one side thereof, a sectional tread having a shoulder rabbeted or undercut upon its under side to receive the beveled edge of the disk to prevent lateral movement and also having a flange extending along one face of the disk and bearing against the sides of said raised seat and having recesses therein, and a plate fitting over said raised seat and extending over said flanges and having projections to engage the before-mentioned recesses in the flanges to prevent radial movement of the sections.

809,399. STEREOTYPE-PLATE HOLDER. CHARLES F. ROCKWOOD, Brooklyn, N. Y., assignor to Rockwood Manufacturing Company, Brooklyn, N. Y., a Corporation of New Jersey. Filed Oct. 28, 1903. Serial No. 178,695.



Claim.—1. A printing-plate holder having a series of clamp-slots and each slot corresponding in width at the surface of the plate-holder and at the base of the slot, and intermediately and oppositely undercut and shouldered with downward-converging walls from the undercut portions.

2. A printing-plate holder having a series of clamp-slots therein, and each slot having opposite parallel walls immediately below the surface of the plate-holder that are undercut and shouldered and inclined walls from the limits of the undercut portions that converge downward toward the bottom of the slot.

3. A clamp device for a printing-plate holder, consisting of the clamp, C, having the threaded portion, C^3, the tumbler, E, threaded and its upper surface having the grooves, E^2, E^2, the screw, D, connecting the clamp and tumbler together, and provided with the pinion-head, D', the washer, F, and the journal-box, F', and all combined, substantially as specified.

4. The combination with a clamp for a printing-plate holder, of the tumbler, E, having the grooves, E^2, E^2, in its upper surface and being connected with the clamp mechanism, substantially as specified.

5. The clamp device for a printing-plate holder having clamp-slots therein consisting of a pair of clamps, C, C, the screw, D, having right-hand and left-hand threaded sections which are fitted to the clamps that are correspondingly threaded, one for each section and the screw being provided with means for its rotation and journaling in said slots, and the tumbler device, E, fitted to the screw in connection with each of the clamps, and all combined, substantially as specified.

6. In combination with a curved printing-plate holder, a clamp device provided with a lateral adjusting-screw and tumbler mechanism, the head of the screw and the edge of the tumbler being curved to make them operative in the slots in the holder, substantially as specified.

7. A clamp device for a curved printing-plate holder having slots therein having a clamp with its under surface convex, a tumbler with its upper surface convex and its adjusting-screw having the under portion of its pinion and the outer portion of its washer convex, and all combined, substantially as specified.

8. A printing-plate holder having a series of clamp-slots therein each one pica wide and each slot having opposite parallel walls immediately below the surface of the plate-holder that are undercut and shouldered and inclined walls from the limits of the undercut portions that converge downward toward the bottom of the slot.

9. A printing-plate holder having a series of clamp-slots therein and each slot having opposite parallel walls for an appreciable distance below the surface of the plate-holder that are undercut and shouldered, and inclined walls from the limits of the undercut portions that converge downward toward the bottom of the slot.

10. A printing-plate holder having a series of clamp-slots therein and each slot having opposite parallel walls for an appreciable distance below the surface of the plate-holder that are undercut and shouldered and also opposite parallel walls at the bottom of the slot which agree in width with the aforesaid walls, and intermediate inclined walls from the limits of the undercut portions that converge downward to conjunction with the parallel walls at the bottom of the slot.

11. A printing-plate holder having a series of clamp-slots therein and each slot having opposite parallel walls for an appreciable distance below the surface of the plate-holder that are undercut and shouldered, the groove being of V form below the limits of the undercut shouldered portion.

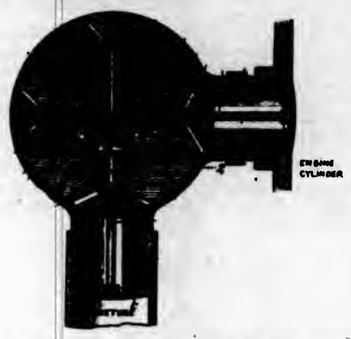
12. A printing-plate holder having a series of clamp-slots and each slot corresponding in width at the surface of the plate-holder and at the base of the slot and intermediately and oppositely undercut and shouldered with downward-converging walls from the undercut portions, and a clamp device adapted to fit down into the groove and having a revoluble screw-stem and swinging tumbler threaded upon and longitudinally movable by said screw-stem, said tumbler having substantially parallel side walls and an upper edge adapted to pass beneath either undercut and shouldered portion with one side wall in close proximity with one converging wall of the plate-holder.

13. A printing-plate holder having parallel series of clamp-slots at right angles to and intersecting one another, and each slot corresponding in width at the surface of the plate-holder and at the base of the slot, and intermediately and oppositely undercut and shouldered with downward-converging walls from the undercut portions.

14. A printing-plate holder having parallel series of clamp-slots at right angles to and intersecting one another each one pica wide, with the intervening squares of the plate-holder each three picas wide, and each slot having opposite parallel walls for an appreciable distance below the surface of the plate-holder that are undercut and shouldered, and inclined walls from the limits of the undercut portions that converge downward toward the bottom of the slot.

809,400. VALVE MECHANISM FOR INTERNAL-COMBUSTION ENGINES. WILLIAM H. SCHOONMAKER, Montclair, N. J. Filed Feb. 11, 1904. Serial No. 193,693.

Claim.—1. The combination of a valve-stem mounted to reciprocate and to turn and having annular or part-annular rack-teeth thereon, and a pinion meshed with the rack-teeth, to impart reciprocal movement thereto.



2. The combination of a casing comprising two communications, valves commanding said communications, crossing valve-stems located in the casing and having annular rack-teeth formed thereon, a rock-shaft extending into the casing, and a pinion or pinions attached to the shaft and meshed with the rack-teeth of the valve-stems.

3. The combination of two crossing valve-stems having annular rack-teeth thereon, and a toothed gear meshed with the said rack-teeth to operate the valve-stems.

4. The combination of a casing having inlet and outlet communications, valves respectively commanding the said communications, crossing stems connected with the valves, a rock-shaft extending into the casing, and means within the casing for simultaneously and positively operating the valves and stems from the rock-shaft.

5. The combination of a casing having inlet and outlet communications, outwardly-opening valves commanding the same, a rock-shaft extending into the casing, and means within the casing for simultaneously and positively operating the valves from said rock-shaft.

6. The combination of a casing having inlet and outlet nipples, outwardly-opening valves seated on the outer end of said nipples, valve-stems connected respectively to the valves and extending into the casing, and a means projecting into the casing and connected with the stems to simultaneously and positively operate the valves.

809,401. RAILROAD-TIE. FRANK SEYMOUR, Lead, S. D., assignor of one-fourth to John Lapp, Rochford, S. D., and one-fourth to Robert H. Driscoll, Lead, S. D. Filed Oct. 4, 1905. Serial No. 281,823.

Claim.—1. A metallic tie-frame including a base provided near the ends thereof with lugs, and head-plates supported thereby.

2. A metallic tie-frame including a base provided near its ends with head-plate-supporting lugs and having an intermediate upward reinforcement.

3. A metallic tie-frame including a base concaved in its under side and provided on its upper side with head-plate-carrying lugs, and an intermediate reinforcement.

4. A metallic tie-frame including a base provided on its upper side with head-plate-carrying lugs and an intermediate reinforcement, said base being provided with a plurality of apertures.

5. A base having lugs and head-plates supported by said lugs, said head-plates having recessed upper corners.

6. A base-plate having lugs, head-plates supported by said lugs, and bolts extending upwardly through the head-plates.

7. A base-plate having lugs, head-plates supported upon said lugs, and bolts extending upwardly through the head-plates and having non-circular heads seated in recesses in the head-plates.

8. A base-plate having lugs, head-plates supported by the lugs, bolts extending upwardly through the head-plates, and a plastic body molded upon the base-lugs and head-plates.

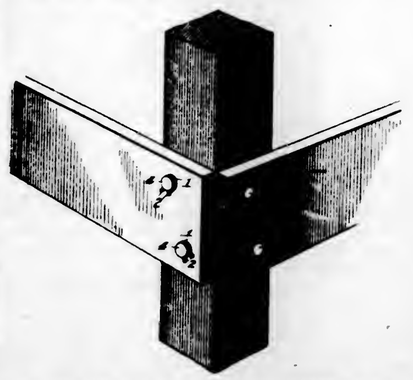
9. A metallic tie-frame including a base having head-plate-supporting lugs, end plates abutting upon the base, and wires connecting said end plates.

10. A metallic tie-frame including a base having head-plate-supporting lugs, end plates abutting upon the base and having slots and outturned flanges, and wires connecting the end plates.

11. A metallic tie-frame including a base-plate having head-plate-supporting lugs, end plates abutting upon the base, wires connecting the end plates, and cross-wires connecting the end-plate-connecting wires.

12. A metallic tie-frame including a base having head-plate-supporting lugs, end plates abutting upon the base, end-plate-connecting wires, and cross-wires connecting the latter, in combination with a plastic body molded upon the frame.

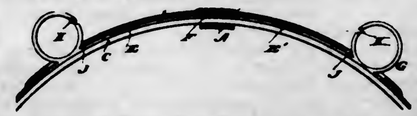
809,402. SCAFFOLD-NAIL. CHARLES E. SPRINGER, Chicago, Ill. Filed Dec. 10, 1904. Serial No. 236,575.



Claim.—1. The combination with a scaffold-nail, of a collar open at one side and arranged beneath the head of the nail to prevent surface contact between the timber and the head of the nail when driven and so that when said collar is removed laterally a space will be provided for the entrance of a tool to readily pull the nail.

2. The combination with a scaffold-nail, of a collar open at one side and arranged beneath the head of the nail to prevent surface contact between the timber and the head of the nail when driven and so that when said collar is removed laterally a space will be provided for the entrance of a tool to readily pull the nail, the said collar having lateral prongs along its side opening for the convenient dislodgment of the collar from underneath the nail-head.

809,403. LINE-HOLDER. CHRISTIAN STRAUBEL, Peoria, Ill. Filed Dec. 22, 1904. Serial No. 238,015.



Claim.—1. As an article of manufacture a long flat metal member curved in the arc of a circle and having near one end a ring, there being a slit in said ring opening upward and inward into the ring, said slit being in the side of the ring nearest the longest extremity of the member carrying it.

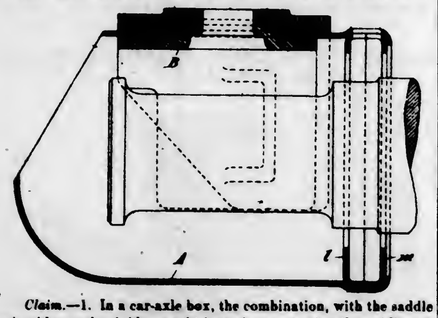
2. In a line-support, a pair of curved rigid members placed end to end in line with one another, a ring carried by each said member, the openings thereof being at right angles to the length of the said

members, there being upwardly and inwardly extending slits in the rings for the passage of the driving-reins in combination with the hip-strap of a harness to which the members are secured, as set forth.

3. In a line-support, a pair of members in line with one another, a ring on each said member, each said ring having an upwardly and inwardly extending slit or opening for the passage of the line, in combination with the hip-strap of a harness, a covering member through which the rings extend, said covering member covering the ring-carrying members, and a member at the adjoining ends of the said ring-carrying members for securing those ends against movement as set forth.

4. The combination with the hip-strap C of a harness, of the flat and long members E and E' lying upon said strap, the housing D inclosing the adjacent ends of the members, the rings G G formed with the said members, there being openings in said rings, and the covering H for covering all but the rings from view.

809,404. **AXLE-BOX FOR RAILWAY-CARS.** HEINRICH STÜTZNE, Witten, Germany. Filed Mar. 17, 1903. Serial No. 148,166.



Claim.—1. In a car-axle box, the combination, with the saddle and guides, and a rigid wrought-iron piece secured to the saddle and guides, of a comparatively light wrought-iron casing secured to said piece and serving to inclose the axle.

2. In a car-axle box, the combination, with the saddle and guides, and a rigid piece secured to the saddle and guides, of a wrought-iron casing secured on the outer side of said piece and serving to inclose the axle.

3. In a car-axle box, the combination, with the saddle and guides, and a rigid piece secured to the saddle and guides, of a comparatively light casing secured between the guides and said piece and serving to inclose the axle.

4. In a car-axle box, the combination, with the saddle and guides, and a rigid piece secured to the saddle and guides by means of a flange, of a comparatively light casing secured between the guides and said piece and serving to inclose the axle.

5. In a car-axle box, the combination, with the saddle and guides, and a rigid wrought-iron piece secured to the saddle and guides and adapted to sustain the shocks transmitted thereby, of a comparatively light casing of wrought-iron arranged between the guides and said piece and serving to inclose the axle, the connection between the rigid piece and the saddle and guides being by a flange in such manner as to rigidly clamp the casing between the piece and guides.

6. In a car-axle box, the combination, with the saddle and guides, and a rigid piece secured to the saddle and guides, of a comparatively light casing secured to said piece and serving to inclose the axle, and a partition arranged within the casing in such manner as to form a packing-chamber.

7. In a car-axle box, the combination, with the saddle and guides, and a rigid piece secured to the saddle and guides, of a comparatively light casing secured to said piece and serving to inclose the axle, said casing having an enlargement at one end, and spaced plates arranged within said enlargement in such manner as to form a packing-chamber.

8. In a car-axle box, the combination, with the saddle and guides, and a rigid piece secured to the saddle and guides, of a comparatively light casing secured to said piece and serving to inclose the axle, said casing having its inner end enlarged and bent inwardly, and a plurality of bent plates disposed within said casing in such manner as to form a packing-chamber.

9. In a car-axle box, the combination, with the saddle and guides, and a rigid wrought-iron piece secured to the saddle and guides, of a comparatively light casing secured to said piece and serving to inclose the axle, said casing having upon its inner end an enlargement, and perforated plates having flanged edges opposed to each other and arranged within the enlargement in such manner as to form a packing-chamber.

10. In a car-axle box, in combination, with the saddle and guides, and a rigid wrought-iron piece secured to the saddle and guides by means of a flange, of a comparatively light wrought-iron casing arranged between the guides and said piece and serving to inclose the axle, and spaced perforated plates disposed within said casing near the inner end in such manner as to embrace the axle and serve as a packing-chamber.

809,405. **METHOD OF SKIMMING SLAG FROM MOLTEN METAL.** MAXIMILIAN M. SUPPES, Elyria, Ohio. Filed July 1, 1903. Serial No. 163,953.

Claim.—1. The herein-described method of skimming slag from liquid metal, which consists in displacing the slag by the immersion, or partial immersion, therein, of a displacing mass or body, having a specific gravity higher than that of the slag and lower than that of the underlying metal.

2. The herein-described method of skimming slag from liquid metal, which consists in displacing the slag by the immersion, or partial immersion, therein of a body of refractory material, having a specific gravity higher than that of the slag and lower than that of the underlying metal.

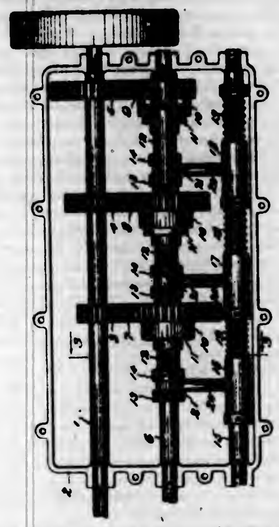
809,406. **VARIABLE-SPEED GEAR.** MORTON C. TALCOTT, Hartford, Conn. Filed Oct. 14, 1905. Serial No. 282,791.

Claim.—1. A gearing having a motor-shaft, gears of different diameters on the motor-shaft, a transmission-shaft, gears of different diameters on the transmission-shaft and meshing with the gears on the motor-shaft, the gears on one shaft being keyed and the gears on the other shaft being loose, clutches adapted to connect the loose gears with their shaft, a reciprocatory bar, dogs carried by the bar and adapted when moved in one direction to cause the closing of the clutches successively, and a wedge-bar arranged to cause a disengagement of the dogs and allow the clutches to successively release, substantially as specified.

2. A gearing having a motor-shaft, gears of different diameters keyed on the motor-shaft, a transmission-shaft, gears of different diameters loose on the transmission-shaft and meshing with the gears on the motor-shaft, clutches adapted to connect the loose gears with the transmission-shaft, a reciprocatory bar, dogs carried by the bar and adapted when moved in one direction to cause the closing of the clutches successively, and a wedge-bar arranged to cause a disengagement of the dogs and allow the clutches to successively release, substantially as specified.

3. A gearing having a motor-shaft, gears of different diameters keyed on the motor-shaft, a transmission-shaft, gears of different diameters loose on the transmission-shaft and meshing with the gears on the motor-shaft, clutches adapted to connect the loose gears with the transmission-shaft, a fixed shaft, sleeves movable on the fixed shaft and adapted to move the clutches, a reciprocatory bar, dogs carried by the bar and adapted when moved in one direction to successively engage and move the sleeves, and a wedge-bar arranged to cause a successive disengagement of the dogs from the sleeves, substantially as specified.

4. A gearing having a motor-shaft, gears of different diameters keyed on the motor-shaft, a transmission-shaft, gears of different diameters loose on the transmission-shaft and meshing with the gears on the motor-shaft, clutches adapted to connect the loose gears with the transmission-shaft, a fixed shaft, sleeves movable on the fixed shaft, arms projecting from the sleeves and arranged to move the clutches, a reciprocatory bar, dogs carried by the bar and adapted when moved in one direction to successively engage and move the sleeves, and a wedge-bar arranged to cause a successive disengagement of the dogs from the sleeves, substantially as specified.



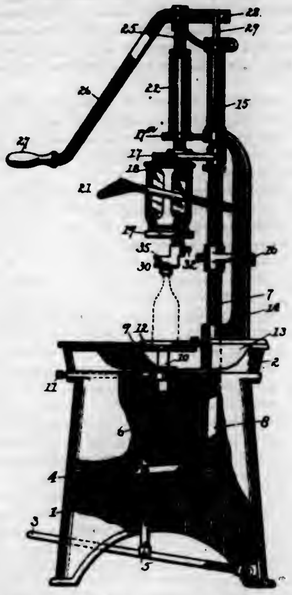
5. A gearing having a motor-shaft, gears of different diameters keyed on the motor-shaft, a transmission-shaft, gears of different diameters loose on the transmission-shaft and meshing with the gears on the motor-shaft, clutches adapted to connect the loose gears with the transmission-shaft, sleeves on the transmission-shaft, springs between the sleeves and the clutches, collars on the sleeves, antifriction-bearings between the collars and the sleeves, a fixed shaft, sleeves movable on the fixed shaft, arms extending outwardly from the sleeves on the fixed shaft, forks connected with the arms and engaging the collars on the sleeves on the transmission-shaft, a reciprocatory bar, dogs carried by the bar and adapted when moved in one direction to successively engage and move the sleeves, and a wedge-bar arranged to cause a successive disengagement of the dogs from the sleeves, substantially as specified.

809,407. **BOTTLE-FILLING MACHINE.** FREDERICK B. THATCHER, Providence, R. I. Filed Dec. 6, 1902. Serial No. 134,161.

Claim.—1. In a bottle-filling machine, in combination with a support and a housing, a filling-tube projecting into the housing, a stopper-engaging device borne on the tube and having means to engage and entirely disconnect the stopper from the bottle and lift and carry it in the lateral movement of the stopper-engaging device, and means for imparting independent longitudinal and lateral movement to said device to disconnect and swing the stopper clear of the mouth of the bottle.

2. In a bottle-filling machine, in combination with a support and a housing appurtenant thereto, a filling-tube projecting into the housing, a stopper-engaging device located on the tube and having means to engage and entirely disconnect the stopper from the bottle and lift and carry it in the lateral movement of the stopper-engaging device, and means for independently lifting and turning said tube to disconnect and remove the stopper from the bottle.

3. In a bottle-filling machine, in combination with a support and a housing appurtenant thereto, a filling-tube projecting into the housing and located eccentrically therein, a foot secured to the tube and adapted to engage a stopper, and means for entirely and independently lifting and turning said tube to remove the stopper from the mouth of a bottle.



4. In a bottle-filling machine, in combination with a support and a housing therefor, a filling-tube projecting into the housing and located eccentrically therein, a foot secured to the tube and having stopper-engaging means to engage and entirely lift and carry the stopper in the lateral movement of the stopper-engaging device and having a fluid-outlet, and means for lifting and axially turning the tube to remove the stopper and locate the fluid-outlet over the mouth of a bottle.

5. In a bottle-filling machine, in combination with a support and a housing appurtenant thereto, a filling-tube projecting into the housing and having a recess located and arranged to entirely lift and carry a stopper, and means for axially turning the tube to remove the stopper from the mouth of a bottle.

6. In a bottle-filling machine, in combination with a support and a housing appurtenant thereto, a filling-tube projecting into the housing and having a recess located and arranged to entirely lift and carry a stopper, and means for lifting and axially turning the tube to remove the stopper from the mouth of a bottle.

7. In a bottle-filling machine, in combination with a support and a housing appurtenant thereto, a filling-tube projecting into the housing, a foot offset from the tube and containing a recess located and arranged to entirely lift and carry a stopper, and means for lifting and axially turning the tube to remove the stopper from the mouth of a bottle.

8. In a bottle-filling machine, in combination with a support and a housing appurtenant thereto, a filling-tube projecting into the housing, a foot offset from the tube and having a recess located and arranged to entirely lift and carry a stopper, and a fluid-outlet, and means for axially turning the tube to remove the stopper and locate the outlet over the mouth of a bottle.

9. In a bottle-filling machine, in combination with a support and a housing, means for reciprocating the housing, a filling-tube extending into the housing, a foot offset from the end of the tube and having a recess located and arranged to entirely lift and carry a stopper, and means for raising and axially turning the tube to remove the stopper from a bottle.

10. In a bottle-filling machine, in combination with a support and a housing, means for reciprocating the housing, a filling-tube, a fluid connection to the filling-tube, a foot offset from the end of the tube and having a recess located and arranged to entirely lift and carry a stopper, and a fluid-outlet, and means for axially turning the tube to remove the stopper and locate the fluid-outlet over the mouth of a bottle.

11. In a bottle-filling machine, in combination with a support and a housing, means for reciprocating the housing, a filling-tube projecting into and located eccentrically to the axis of the housing, a fluid connection with the filling-tube, a foot offset from said tube and having a recess located and arranged to entirely lift and carry a stopper, and a fluid-outlet, and means for axially turning the tube to remove the stopper and locate the fluid-outlet over the mouth of a bottle.

12. In a bottle-filling machine, in combination with a support and a housing, a filling-tube projecting into the housing and having means located and arranged to entirely lift and carry a stopper, and a handle-lever secured to the tube to turn it to remove the stopper from the mouth of a bottle.

13. In a bottle-filling machine, in combination with a support and a housing, a filling-tube projecting into the housing and having means located and arranged to entirely lift and carry a stopper, a handle-lever secured to the tube to turn it, and a guide for said lever.

14. In a bottle-filling machine, in combination with a support and a housing, a filling-chamber located above the housing, a filling-tube extending through said chamber into the housing, a fluid connection to said fluid-chamber, means on the end of a tube located and arranged to entirely lift and carry a stopper, and means for axially turning the tube to carry the stopper from the mouth of a bottle.

15. In a bottle-filling machine, in combination with a support and a housing appurtenant thereto, a filling-tube projecting into the housing, a stopper-holding device having a recess for the entrance of a stopper and an enlarged recess for holding the stopper in the final placing of the bottle before movement of the stopper-holding device to remove the stopper, and means for operating the stopper-engaging device to entirely lift and carry the stopper.

16. In a bottle-filling machine, in combination with a support and a housing therefor, a filling tube projecting into the housing, a foot on the end of the tube having a lipped recess extending lengthwise of the foot, and a holding-recess located in the upper surface of the lips for the final placing of a stopper before movement of the foot to remove the stopper.

17. In a bottle-filling machine, in combination with a support and a housing appurtenant thereto, a filling-tube projecting into the housing, a stopper-engaging device having a lipped recess and an enlarged recess at the back portion thereof for the final reception of a stopper before movement of the stopper-engaging device to remove the stopper, and means for operating the stopper-engaging device.

18. In a bottle-filling machine, in combination with a support and a housing appurtenant thereto, a filling-tube projecting into the housing, a foot on the end of a tube having a lipped recess extending lengthwise of the foot and a lateral recess for the final reception of a stopper before movement of the foot to remove the stopper opening out of the lengthwise recess, and means for operating the tube.

19. In a bottle-filling machine, in combination with a support and a housing therefor, a filling-tube, a foot secured to the end of the tube and having a recess for the reception of a stopper and an enlarged recess at the back portion thereof for finally receiving a stopper before movement of the foot to remove it, and means for operating the tube.

20. In a bottle-filling machine, in combination with a support and a housing appurtenant thereto, a filling-tube projecting into the housing, stopper-engaging means located on the tube to entirely lift and carry a stopper, and means for lifting and axially turning said tube.

21. In a bottle-filling machine, in combination with a support and a housing appurtenant thereto, a filling-tube projecting into the housing and eccentrically located therein, stopper-engaging means on the end of the tube to entirely lift and carry a stopper and means for lifting and axially turning said tube.

22. In a bottle-filling machine, in combination, a support, a housing appurtenant to the support, a filling-tube extending into and located eccentrically of the housing, an offset foot from said tube having means for receiving a stopper to entirely lift and carry it, and means for operating the tube.

23. In a bottle-filling machine, in combination with a support and a housing appurtenant thereto, a filling-tube projecting into the housing and having a recess located and arranged to entirely lift and carry a stopper, and means for axially turning the tube to remove the stopper in a lateral direction from the mouth of a bottle.

24. In a bottle-filling machine, in combination with a support and a housing appurtenant thereto, a filling-tube projecting into the housing and having a recess located and arranged to entirely lift and carry a stopper, and means for lifting and axially turning the tube to remove the stopper in a lateral direction from the mouth of a bottle.

25. In a bottle-filling machine, in combination with a support and a housing appurtenant thereto, a filling-tube projecting into the housing, a foot offset from the tube and containing a recess located and arranged to entirely lift and carry a stopper, and means for lifting and axially turning the tube to remove the stopper in a lateral direction from the mouth of a bottle.

26. In a bottle-filling machine, in combination with a support and a housing appurtenant thereto, a filling-tube projecting into the housing, a foot offset from the tube and having a recess located and arranged to entirely lift and carry a stopper and a fluid-outlet, and means for axially turning the tube to remove the stopper in a lateral direction and locate the outlet over the mouth of the bottle.

27. In a bottle-filling machine, in combination with a support and a housing, means for reciprocating the housing, a filling-tube extending into the housing, a foot offset from the end of the tube and having a recess located and arranged to entirely lift and carry a stopper, and means for raising and axially turning the tube to remove the stopper in a lateral direction from the mouth of the bottle.

28. In a bottle-filling machine, in combination with a support and a housing, means for reciprocating the housing, a filling-tube, a fluid connection to the filling-tube, a foot offset from the end of the tube and having a recess located and arranged to entirely lift and carry a stopper and a fluid-outlet, and means for axially turning the tube to remove the stopper in a lateral direction from and locate the fluid-outlet over the mouth of the bottle.

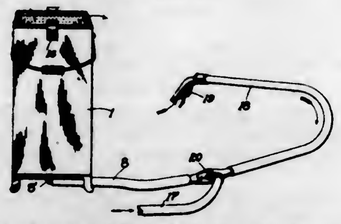
29. In a bottle-filling machine, in combination with a support and a housing, means for reciprocating the housing, a filling-tube projecting into and located eccentrically to the axis of the housing, a fluid connection with the filling-tube, a foot offset from said tube and having a recess located and arranged to entirely lift and carry a stopper and having a fluid-outlet, and means for axially turning the tube to remove the stopper in a lateral direction from and locate the fluid-outlet over the mouth of the bottle.

30. In a bottle-filling machine, in combination with a support and a housing appurtenant thereto, a filling-tube projecting into the housing, stopper-engaging means located on the tube to entirely lift and carry a stopper, and means for axially turning said tube and lifting it independently of its turning movement.

31. In a bottle-filling machine, in combination with a support and a housing appurtenant thereto, a filling-tube projecting into the housing and eccentrically located therein, stopper-engaging means on the end of the tube to entirely lift and carry a stopper, and means for axially turning said tube and for lifting it independent of its turning movement.

32. In a bottle-filling machine, in combination, a filling-tube having a foot on the end thereof containing a lipped recess extending lengthwise of the foot and a holding-recess located in the upper surface of the lips for the final reception of a stopper before movement of the foot to remove the stopper.

809,408. **DUST-COLLECTOR.** JOHN S. THURMAN, St. Louis, Mo. Filed May 6, 1905. Serial No. 259,248.



Claim.—1. A dust-collector comprising a suitable receptacle open at the top, a strainer-hood confined within and snugly embraced by the walls of the same, means for conveying a current of dust-laden air into the receptacle beneath the hood, a shield interposed in the path of the current for arresting the dust, and means providing for the escape of the filtered air through the top of the receptacle, substantially as set forth.

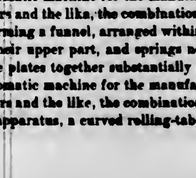
2. A dust-collector comprising a suitable receptacle open at the top, a removable strainer-hood supported within the same a suitable distance above the bottom thereof, means for conducting a current of dust-laden air into the bottom of the receptacle, a shield confined within the receptacle beneath and contiguous to the hood for intercepting the dust, and means providing for the escape of the filtered air through the top of the receptacle, substantially as set forth.

3. In a dust-collector, a strainer-hood comprising a box open at opposite ends, a strainer composed of a dust-intercepting web disposed in a series of folds between said open ends, the sides of the folded sections being secured to the adjacent walls of the box, a receptacle embracing the walls of the box, and a dust-intercepting layer interposed between the box and receptacle, substantially as set forth.

In a dust-collector, a strainer-hood comprising a box open at opposite ends, a strainer composed of a web of cloth disposed in a series of folds between said open ends, strips inserted on opposite sides between the folds, the edges of the latter being folded against the strips between the latter and the adjacent walls of the box, and the strips secured to the said walls, the ends of the web being secured to the walls opposite thereto and a receptacle snugly embracing the walls of the box, substantially as set forth.

5. In a dust-collector, a strainer-hood comprising a box open at opposite ends, a strainer composed of a web of cloth disposed in a series of folds between said open ends, the sides of the folded sections being secured to the adjacent walls of the box, and the ends of the web being secured to the walls opposite thereto, a covering of felt for the box and a receptacle snugly embracing the walls of the box, substantially as set forth.

809,409. **PNEUMATIC TIRE.** PARDON W. TILLINGHAST, Edgewood, R. I. Filed Mar. 5, 1903. Serial No. 146,396.



Claim.—1. A pneumatic tire, having an air-tube constructed of caoutchouc the surfaces of which are rendered non-viscous and un vulcanizing for the purpose of facilitating repairs.

2. A pneumatic tire including an unsulfurized atmospherically-treated air-tube said air treatment being for the purpose of rendering the surface of said tube non-viscous, an outer covering of vulcanized rubber and a ply or plies of fabric between the said covering and the tube.

3. A pneumatic tire including an air-tube, an outer tube of rubber and a ply or plies of fabric, said air-tube having its overlapping joints and parts made of unsulfurized caoutchouc and having its exposed surface atmospherically treated to facilitate repairs.

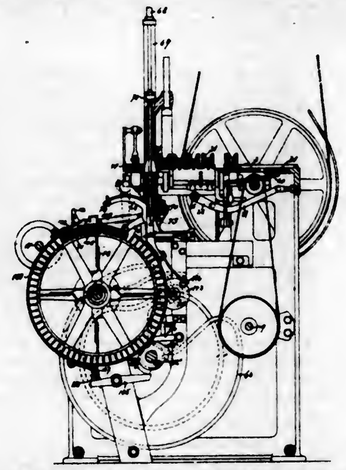
4. A pneumatic tire composed of the following elements, an unsulfurized, atmospherically-treated air-tube said treatment being for the purpose of rendering non-viscous the surfaces only of said tube for the purpose of facilitating repairs means connected to said tube whereby air may be supplied to the same, an outer covering of vulcanizable rubber a ply or plies of fabric which together with said covering is vulcanized into an integral mass inclosing said air-tube.

809,410. **MACHINE FOR THE MANUFACTURE OF CIGARS, CIGARETTES, CIGAR-FILLERS, AND THE LIKE.** MAX VAN GULPEN, Mülheim-on-the-Rhine, Germany. Filed Jan. 14, 1905. Serial No. 240,614.

Claim.—1. In an automatic machine for the manufacture of cigars, cigarettes, cigar-fillers, and the like, which during one revolution of the main shaft completes one cigar, cigarette, cigar-filler, or the like, the combination of filler-molds; means for transferring bunches from the molds to the rolling mechanism, rolling apparatus arranged underneath said molds consisting of a bunching-roller and a presser-roller, a rolling-table, a recess in said table, a rolling-apron covering said table and recess; a forming apparatus receiving the cigars from the rolling apparatus; a fan in said forming apparatus; and circular knives to trim the ends of the cigars or the like, substantially as set forth.

2. In an automatic machine for the manufacture of cigars, cigarettes, cigar-fillers and the like, the combination of a frame and two thin flat plates forming a funnel, arranged within said frame mounted on pivots at their upper part, and springs normally holding the lower parts of the plates together substantially as set forth.

3. In an automatic machine for the manufacture of cigars, cigarettes, cigar-fillers and the like, the combination of a mechanically-operated rolling apparatus, a curved rolling-table with a recess and a funnel into which the tobacco is pushed by a plunger, a bunching and a pressure roller carried to and fro over the rolling-table during the rolling action and mounted rigidly in a single common firm frame so that no difference in the pressure and rolling action is possible, and means for imparting a shaking motion to said bunching and pressure rollers as they are carried to and fro over the rolling-table substantially as set forth.



4. In an automatic machine for the manufacture of cigars, cigarettes, cigar-fillers, and the like, the combination of a rotatable drum, forming-molds on its circumference, a fan within said drum, and a cutting apparatus arranged to cut the ends of the cigars or the like while in said molds, substantially as set forth.

809,411. **BOOKBINDER'S GAGE.** ALWIN VON AUW, New York, N. Y. Filed Aug. 8, 1904. Serial No. 220,026.

Claim.—1. A bookbinder's gage presenting a sheet-supporting surface provided with elevations at two or more margins forming sheet-positioning devices, and having means for accurately positioning a plurality of strips of material in relation to a sheet resting upon said sheet-supporting surface.

2. A bookbinder's gage having a bed-plate provided with marginal elevations and presenting a sheet-supporting surface provided with strip-receiving channels.

3. In a bookbinder's gage, the combination with a bed-piece having a plurality of strip-receiving channels, of means for simultaneously removing the strips from all of said channels.

4. In a bookbinder's gage, the combination with a sheet-supporting member provided with means for positioning a plurality of strips, of devices for lifting the sheet and the strips off the sheet-supporting member.

5. In a bookbinder's gage, the combination with a bed-piece presenting a sheet-supporting surface provided with a plurality of strip-receiving channels, of a lifter comprising a plurality of arms normally resting in said channels.

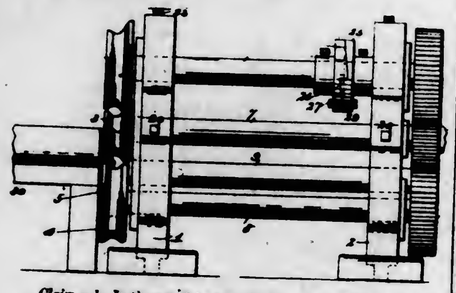
6. In a bookbinder's gage, the combination with a bed-plate presenting a sheet-supporting surface provided with strip-receiving channels, of a lifting device comprising a plurality of arms somewhat narrower than said channels and normally resting in said channels.

7. In a bookbinder's gage, the combination with a bed-plate presenting a sheet-supporting surface provided with strip-receiving channels having narrower channels formed in the bottoms thereof, of a plurality of lifter-arms secured at one end and normally resting in said narrower channels.

8. In a bookbinder's gage, the combination with means for supporting a sheet of material and means for accurately positioning a

plurality of strips in relation thereto, of a device for lifting the sheet and the strips simultaneously from the gage, and means for limiting the movement of said lifting device.

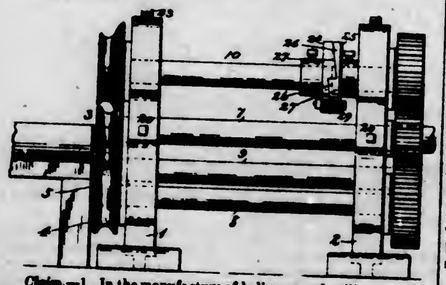
809,412. ART OF FORMING HELICES FOR CHAIN-LINKS. ISAAC D. WEAVER, Lebanon, Pa., assignor of one-half to Samuel B. Light, Lebanon, Pa. Filed June 10, 1903. Renewed June 10, 1905. Serial No. 264,734.



Claim.—1. In the art of forming helices, the method which consists in heating the metal, forcibly condensing or staving up the metal on the inside of the helix and maintaining the fiber of the metal on the outside thereof in substantially normal and uniform condition.

2. In the art of forming helices, the method which consists in heating the metal, forcibly condensing or staving up the metal on the inside of the helix by retarding the flow of the metal, and maintaining the fiber of the metal on the outside thereof in substantially normal and uniform condition.

809,413. MANUFACTURE OF HELICES FOR CHAIN-LINKS. ISAAC D. WEAVER, Lebanon, Pa., assignor of one-half to Samuel B. Light, Lebanon, Pa. Filed June 10, 1903. Renewed June 10, 1905. Serial No. 264,736.

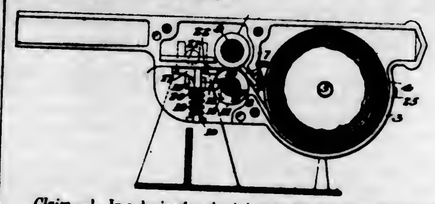


Claim.—1. In the manufacture of helices, a rod-coiling machine having rolls or disks provided with grooved perimeters, said rolls being of different diameters and adapted to receive a rod of metal and move the same, and means for rotating the rolls in opposite directions and constructed to rotate one of the rolls at a slower speed than the other roll, whereby the metal on the inside of the helix is condensed or staved up, and the fiber of the metal of the outside maintained in substantially normal and uniform condition.

2. In the manufacture of helices, a rod-coiling machine having rolls or disks provided with grooved perimeters, said rolls being of different diameters and the smallest one of which is arranged central to the other rolls, and the center of the upper roll a greater distance from the center of the smallest roll than the center of the lower roll, and means for rotating the rolls in opposite directions and constructed to rotate the perimeter of the upper roll at a slower speed than the lower roll, whereby the metal on the inside of the helix is condensed or staved up, and the fiber of the metal on the outside thereof maintained in substantially normal and uniform condition.

3. In the manufacture of helices, a rod-coiling machine having rolls or disks provided with grooved perimeters, said rolls being of different diameters and the smallest one of which is arranged central to the other rolls, and the upper roll provided with an extensible and contractible shaft for varying the spaces between the coils.

809,414. TOY CANNON. JAMES B. WEAVER, Allegheny, Pa. Filed Nov. 28, 1904. Serial No. 234,467.



Claim.—1. In a device for obtaining explosions in rapid succession, a pair of feed-rolls arranged to feed forward a strip provided with separated portions of an explosive, means for continuously rotating said rolls, a reciprocating hammer, and mechanism for reciprocating said hammer as the separated portions of explosive are brought into registry therewith; substantially as described.

2. In a device for obtaining explosions in rapid succession, a pair of feed-rolls having gripping portions and cut-away portions to allow the passage of separated portions of an explosive on a flexible strip, means for continuously rotating said rolls, a reciprocating hammer, and a rotary crank device having connections arranged to move the hammer in at least one direction of its reciprocation; substantially as described.

3. In a device for obtaining explosions in rapid succession, a pair of feed-rolls, means for continuously rotating said rolls, a spring-actuated reciprocating hammer, an opposite anvil, and means for retracting the hammer to deliver a blow upon the successive portions of explosive; substantially as described.

4. In a device for obtaining explosions in rapid succession, a magazine-chamber arranged to contain a reel of flexible material carrying separated portions of an explosive, an exploding-chamber connected with the magazine-chamber by a channel through which the strip is fed, a feeding device in the exploding-chamber, means for continuously moving the feeding device, a reciprocating hammer therein arranged to deliver successive blows upon the successive separated portions of the explosive and means for reciprocating said hammer; substantially as described.

5. In a device for obtaining explosions in rapid succession, a magazine-chamber, an exploding-chamber connected to the magazine-chamber by a narrow channel through which the strip of material carrying the explosive is fed, a pair of feed-rolls in the exploding-chamber, means for continuously rotating the feed-rolls, a reciprocating hammer, and connections arranged to reciprocate said hammer; substantially as described.

6. In a device for obtaining explosions in rapid succession, a magazine-chamber arranged to receive a coil of flexible material carrying separated portions of an explosive, an exploding-chamber connected to the magazine-chamber by a channel through which the strip is fed, a pair of feed-rolls in the exploding-chamber having grooves or cut-away portions to allow passage of the explosive, one of said feed-rolls having cam portions, a reciprocating spring-pressed hammer arranged to be actuated by the cam, and a crank or similar device for turning the feed-rolls; substantially as described.

7. In a device for obtaining explosions in rapid succession, a magazine-chamber arranged to receive a coil of flexible material carrying separated buttons of an explosive, an exploding-chamber connected therewith by a narrow channel through which the strip is fed, feed-rolls, means for continuously rotating said rolls, a reciprocating hammer within the exploding-chamber, and means for closing the channel into the magazine-chamber when the explosion takes place; substantially as described.

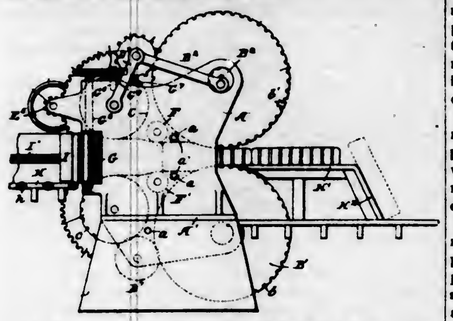
8. In a device for obtaining explosions in rapid succession, a pair of feed-rolls, means for turning the same continuously, a reciprocating hammer, connections between the feed-rolls and hammer arranged to retract said hammer, and means for returning it to strike the explosive; substantially as described.

809,415. ROLLER-COMPRESS. SAMUEL J. WEBB, Hinden, La. Filed Jan. 16, 1903. Serial No. 1,089.

Claim.—1. In an apparatus for compressing bales of cotton, the combination of grooved rollers between which the bale is compressed, and means for forcing the bale between the rollers, substantially as described.

2. In an apparatus for compressing bales of cotton, the combination with rollers between which the bale is compressed, of means for rotating said rollers, substantially as described.

3. In an apparatus for compressing bales of cotton, the combination of rollers between which the bale is compressed, the rollers being constructed and arranged to permit the tying of the bale while under pressure, substantially as described.



4. In an apparatus for compressing bales of cotton, the combination of rollers between which the bale is compressed, the rollers being provided with slots in their peripheries through which the bale-ties may be passed, substantially as described.

5. In an apparatus for compressing bales of cotton, the combination of rollers between which the bale is compressed, the rollers being provided with longitudinally-removable peripheral sections leaving slots between them for the reception of the bale-ties, substantially as described.

6. In an apparatus for compressing bales of cotton, the combination with rollers between which the bale is compressed with respect to thickness, of rollers between which the bale is compressed laterally with respect to breadth, and means for preventing the lateral extension of the bale while being compressed with respect to thickness, substantially as described.

7. In an apparatus for compressing bales of cotton, the combination with rollers between which the bale is compressed with respect to thickness, of means for positively operating the rollers and means for limiting the longitudinal extension of the bale while being compressed, substantially as described.

8. In an apparatus for compressing bales of cotton, the combination with rollers between which the bale is compressed with respect to thickness, of rollers for compressing the bale with respect to breadth, means for positively operating both sets of said rollers and means for limiting the longitudinal extension of the bale while being compressed, substantially as described.

9. In an apparatus for compressing bales of cotton, the combination with rollers between which the bale is compressed with respect to thickness, of rollers for compressing the bale with respect to width, means for positively operating both sets of said rollers and means for forcing the bale between the rollers and limiting the longitudinal extension of the bale, substantially as described.

10. In an apparatus for compressing bales of cotton, the combination with main compress-rollers between which the bale is compressed with respect to thickness, of preliminary compress-rollers, and rollers between which the bale is compressed with respect to width, and means for positively operating all of said rollers, substantially as described.

11. In an apparatus for compressing bales of cotton, the combination with main compress-rollers between which the bale is compressed with respect to thickness, of preliminary compress-rollers, rollers between which the bale is compressed with respect to breadth, means for positively operating all of said rollers and means for forcing the bale between the rollers, substantially as described.

12. In an apparatus for compressing bales of cotton, the combination with main compress-rollers between which the bale is compressed, of preliminary compress-rollers, means for positively operating all of said rollers and guides arranged between the two sets of rollers, substantially as described.

13. In an apparatus for compressing bales of cotton, the combination with main compress-rollers between which the bale is compressed, of preliminary compress-rollers, means for positively operating all of said rollers and connections between the two sets of rollers whereby they are driven at proper speeds with relation to each other, substantially as described.

14. In an apparatus for compressing bales of cotton, the combination with preliminary compress-rollers, of main compress-rollers, the latter being provided with grooves transverse to the peripheries of the rollers whereby the bale can be tied while the bale is under full compression between the rollers, substantially as described.

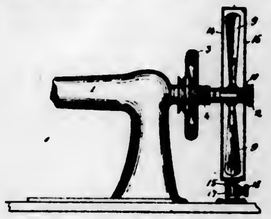
15. In an apparatus for compressing bales of cotton, the combination with main compress-rollers between which the bale is compressed, of preliminary compress-rollers operating at right angles to the main compress-rollers, means for positively operating all of said rollers and a feeding-platform provided with rollers arranged to deliver the bale to the preliminary compress-rollers, substantially as described.

16. In an apparatus for compressing bales of cotton, the combination with main compress-rollers between which the bale is compressed, means for positively operating said rollers, means for preventing the lateral extension of the bale while being pressed, and means whereby the ties may be applied for securing the bale in its compressed form, substantially as described.

17. In an apparatus for compressing bales of cotton, the combination with main compress-rollers between which the bale is compressed, means for positively driving said rollers, said rollers being provided with grooves transverse to their periphery, and a frame supporting said compress-rollers, the frame being shaped to permit access to the bale while being compressed, substantially as described.

18. In an apparatus for compressing bales of cotton, the combination with rollers between which the bale is compressed with respect to thickness, of rollers between which the bale is compressed laterally with respect to breadth, means for preventing the lateral extension of the bale while being compressed with respect to thickness, means for limiting the longitudinal extension of the bale while being compressed, and means whereby the ties may be applied for securing the bale while under final compression, substantially as described.

809,416. FAN ATTACHMENT FOR SEWING-MACHINES. LEOPOLD WEINSTEIN and JOSEPH PERLSTEIN, Chicago, Ill. Filed Feb. 25, 1905. Serial No. 247,236.



Claim.—1. In a fan attachment for sewing-machines, an axle provided with a collar and having screw-threaded ends, a fan rotatably mounted on the axle, means for regulating the frictional engagement between the fan and collar on the axle substantially as described.

2. In a fan attachment, an axle provided with a screw-thread at each end and having a collar secured thereto, a fan having a hub provided with an annular recess at one end rotatably mounted on said axle, a thumb-nut threaded on the outer end of the axle whereby the fan is prevented from accidental displacement with said axle as and for the purpose described.

3. The combination with the fly-wheel of a sewing-machine, of an axle provided with a collar and having one end threaded in an aperture in the fly-wheel, and a fan rotatably mounted on the axle and means for holding the fan on the axle substantially as set forth.

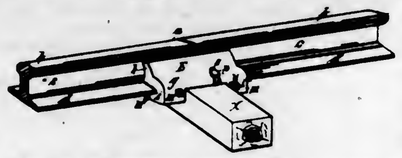
4. The combination with a sewing-machine of an axle carried by the fly-wheel of the sewing-machine and a fan rotatably mounted on said axle, a thumb-nut threaded on the axle and a spring inserted between the thumb-nut and hub of the fan as and for the purpose set forth.

5. In a device of the character described, an axle provided with a stationary collar threaded in the hub of a fly-wheel of a sewing-machine, a fan on the axle end provided with an annular recess in the outer end of its hub, a spiral spring seated in said annular recess, a thumb-nut threaded on the outer end of the axle whereby the tension of the spring is regulated, as and for the purpose set forth.

6. In a fan attachment for sewing-machines, an axle having a stationary collar and provided with screw-threaded ends secured to the fly-wheel of a sewing-machine, a fan having a hub provided with an annular recess at one end rotatably mounted on said axle, a spiral spring seated in the annular recess of the fan-hub, a thumb-nut

threaded against the spiral spring on the axle, substantially as described.

809,417. CONTINUOUS-RAIL JOINT AND CLAMP. WILLIAM J. WILLIAMS, Terre Haute, Ind. Filed Oct. 2, 1905. Serial No. 280,915.



Claim.—In a continuous-rail joint and clamp, the combination of two rails, provided with corresponding beveled ends adapted to coincide and with notched bases, adapted to engage lugs provided therefor, with a two-section clamp, consisting of two opposing jaws adapted to engage the sides of the rails, a recess in said jaws adapted to receive the base-flanges of the rails and pendent feet provided with inwardly-projecting arms, adapted to oppose one another beneath said rails, and two bolts adapted to bind the sections of the clamp together upon the rails all substantially as shown and for the purpose set forth.

809,418. ART OF MANUFACTURING WINDOW-GLASS. LÉON APPERT, Paris, France. Filed Mar. 22, 1905. Serial No. 251,411.

Claim.—1. An improvement in the art of producing plates of glass, which consists, in first forming a hollow closed-top blank of glass in the shape of a conic frustum, next in transforming the blank thus produced into a bulbous or ovoid shaped body by subjecting it to the action of heat until it is rendered sufficiently plastic, and, while in that condition, imparting to it a rotary motion upon its axis, at the same time that a current of air is being forced into its interior, and next, in changing the position of the bulbous or ovoid shaped body thus produced end for end and transforming it into a plate or disk by reheating it, and, when sufficiently plastic, imparting to it a rotary motion upon its axis, substantially as described.

2. An improvement in the art of producing plates of glass, which consists, in first casting a hollow closed-top blank of glass in the form of a conic frustum, next in transforming this blank into a bulbous or ovoid shaped body, by subjecting it to the action of heat until it is rendered sufficiently plastic, and, while in that condition, imparting to it a rotary motion upon its axis, at the same time that a current of air is forced into its interior, and next, in changing the position of the bulbous or flattened-ovoid shaped body thus produced end for end and transforming it into a plate or disk by reheating it, and, when sufficiently plastic, imparting to it a rotary motion upon its axis, substantially as described.

3. An improvement in the art of producing plates of glass, which consists, in first casting a hollow closed-top blank of glass in the form of a conic frustum, next in transforming this blank into a bulbous or ovoid shaped body by subjecting it to the action of heat until it is rendered sufficiently plastic, and, while in that condition, imparting to it a rotary motion upon its axis at the same time that a current of air is forced into its interior, next in changing the position of the bulbous or ovoid shaped body thus produced end for end and transforming it into a plate or disk by reheating it, and, when sufficiently plastic, imparting to it a rotary motion upon its axis, and next in annealing the plate or disk thus formed, substantially as described.

4. An improvement in the art of producing plates of glass, which consists, in first casting a hollow closed-top blank of glass in the form of a conic frustum, next in transforming this blank into a bulbous or flattened-ovoid body by subjecting it to the action of heat until it is rendered sufficiently plastic, and, while in that condition, imparting to it a rotary motion upon its axis, as well as an up-and-down movement, at the same time that a current of air is forced into its interior, next in changing the position of the bulbous or flattened-ovoid shaped body thus produced end for end and transforming it into a plate or disk by reheating it, and, when sufficiently plastic, imparting to it a rotary motion upon its axis, and next in annealing the plate or disk thus formed, substantially as described.

5. An improvement in the art of producing plates of glass, which consists, in first casing a hollow closed-top blank of glass in the form of a conic frustum, next in clamping this blank with its open end downward upon a rotary platform, next in transforming this blank into a bulbous or flattened-ovoid shaped body by subjecting it to the action of heat in an oven until it is rendered sufficiently plastic, and, while in that condition, imparting to it a rotary motion upon its axis, as well as a vertical up-and-down movement at the same time that a current of air is being forced into its interior, next in cooling the same and securing it to a second rotary platform with its open end upward, next in transforming the bulbous or flattened-ovoid shaped body thus produced into a plate or disk by reheating it in an oven, and, when sufficiently plastic, imparting to it a rotary motion upon its axis, and next in annealing the plate or disk thus produced, substantially as described.

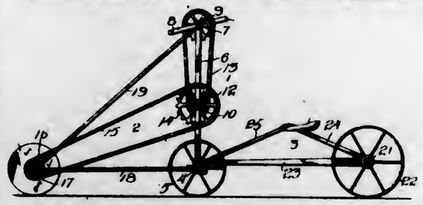
809,419. DISPENSING DEVICE. GILBERT L. BELCHER, San Francisco, Cal. Filed Jan. 25, 1905. Serial No. 242,640.

Claim.—1. A dispensing device comprising a longitudinally-slitted tubular holder having a discharge-orifice at one end, a friable wafer on the inside of the tube and covering the slit therein, a follower operating in a tube, and means separate from the follower and movably mounted on the outside of the tube and having a member operating through said slit to operate the follower.

2. A dispensing device comprising a longitudinally-slitted inflexible tube having a discharge-orifice at one end, a closure for the slit, a follower in the tube, and means separate from the follower and movably mounted on the outside of the tube and having a member operating through the slit, to open the closure and to actuate the follower.

3. A tubular holder having a discharge-orifice, a follower therein, a cutting device movable in the direction of the length of the holder and a sleeve on the outside of the holder and carrying the cutting device, said cutting device engaging the follower to advance it to eject the contents of the holder.

809,420. SMOOTHING AND POLISHING MACHINE. LEROY A. BERRY, Hartford, Mo. Filed Feb. 15, 1904. Serial No. 193,720.

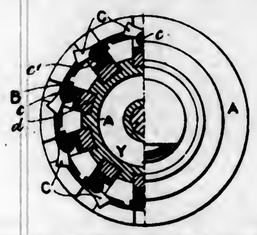


Claim.—A smoothing and polishing machine, comprising an ambulant carriage, a frame connected to and projecting from the front end thereof, an abrasive roll mounted in the frame, and driving means for said roll comprising hand-cranks and sprockets also mounted in said frame, said roll and driving means being adjustable in a vertical plane by the pivotal movement of said frame.

809,421. EXPANSIBLE SPROCKET. ARTHUR W. BOON, Brixton, England. Filed Jan. 27, 1904. Serial No. 190,842.

Claim.—1. In a variable sprocket-wheel the combination with a drum having a series of radially-arranged slots, of a series of adjustable blocks forming a variable circumference to said drum, of teeth pivoted in recesses in said blocks, and of springs operating to retain said teeth in their operative positions but allowing them to give way when they are inoperative, as set forth.

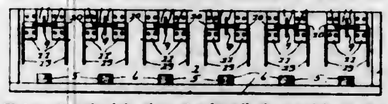
2. A variable sprocket-wheel comprising a drum A, a series of blocks B adjustably mounted in radial slots in said drum, teeth C pivoted transversely in recesses in said blocks, springs C' operating to retain said teeth in their active positions, and means for varying the positions of the blocks in the radial slots in the drum, as set forth.



3. In a variable sprocket-wheel comprising a drum A, a series of blocks B arranged to slide in radial slots in said drum and means for varying the positions of said blocks in said drum, sprocket-teeth C pivoted to said blocks having one face shaped to engage the links of the sprocket-chain so as to receive from it or impart to it motion in one direction, the other face of the teeth being so shaped that it will not engage with the sprocket-chain but turn on its pivot and so become inoperative, as set forth.

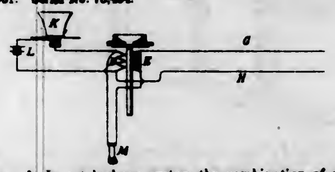
4. The combination in a variable sprocket-wheel of a drum A having a series of radial slots, a series of blocks B mounted to slide in the slots in said drum, teeth C pivoted transversely to the blocks B, springs C' operating to keep the teeth C in their operative positions with reference to the circumference of the wheel, and means for varying the positions of the blocks in the radial slots in the drum, as set forth.

809,422. LANTERN-GLOBE RACK. CHARLES F. BOWMASTER, Litchfield, Ill. Filed June 20, 1905. Serial No. 267,602.



Claim.—A rack of the character described comprising a support consisting of a base and a back, a cushioned projection upon said base adapted to engage a lantern-globe or the like, bearings upon said back, a bracket constructed of bent wire and consisting of a globe-engaging loop, a finger-piece, pivot-arms mounted in said bearings and stops at the ends of said arms, and a spring upon said bracket for holding said stops normally in engagement with said back, substantially as described.

809,423. TELEPHONE. CHARLES G. BURKE, Brooklyn, N. Y., assignor of one-half to John Q. A. Whittemore, Boston, Mass. Filed Sept. 16, 1901. Serial No. 75,494.

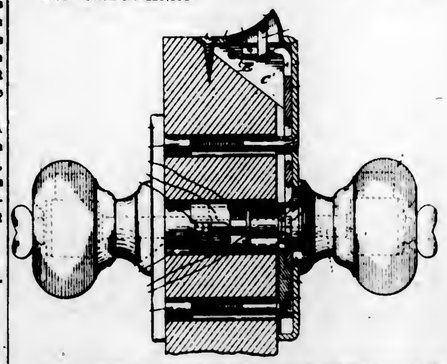


Claim.—1. In a telephone system the combination of a local transmitter comprising a battery and a transmitting-circuit, a main-line circuit, a receiver comprising a diaphragm, a core for operating the said diaphragm, an induction-coil surrounding the said core for magnetically affecting the said core and having two coils, one of said coils formed of coarse wire of few turns and connected in series with the said local circuit, the other of said coils formed of fine wire of many turns and connected in series with the said coil of coarse wire and the main line, as set forth.

2. In a telephone system the combination of a local transmitting-circuit comprising a battery and a transmitter, of main-line circuit, a receiving means comprising two magneto-telephones, one of said telephones having a diaphragm, a magnetic core for operating said diaphragm, an induction-coil surrounding the said core and for magnetically affecting the said core and having two coils, one of said coils being formed of coarse wire of few turns and in series with the said local transmitting-circuit and in shunt of the main-line circuit, the other of said coils formed of fine wire of many turns and connected in series with the main line and the other telephone, as set forth.

3. In a telephone system the combination of a transmitting-circuit comprising a battery and a transmitter, a main-line circuit, a telephone-receiver having a diaphragm, a core for operating the said diaphragm, an induction-coil located on the said core having two coils, one of said coils constituting a transmitting-coil connected in series with the said transmitting-circuit, the other of said coils constituting a receiving-coil and connected in series with the said main-line circuit and in series with two parts of the said transmitting-circuit one of the said parts comprising the said transmitting-coil.

809,424. LOCK. CHARLES J. CALEY and HENRY G. VOIGHT, New Britain, Conn., assignors to The Russell and Erwin Manufacturing Company, New Britain, Conn., a Corporation of Connecticut. Filed Oct. 19, 1904. Serial No. 229,004.



Claim.—1. In a lock, a latch-slide, a knob and connections for operating said slide, a dogging device carried by said slide and means carried by said knob for operating said dogging device to check the movement of said slide.

2. In a lock, a latch-slide, a knob and connections for operating said slide, a dogging device carried by said slide and movable independently thereof and a stop arranged to coact with said dogging device and means operable through said knob for moving said dogging device.

3. In a lock, a reciprocating latch-slide, a knob, a dogging-slide carried by said reciprocating latch-slide said dogging-slide moving in a plane at an angle to that of the latch-slide, a stop coacting with said dogging-slide and means accessible through said knob for operating said dogging-slide.

4. In a lock, a reciprocating latch-slide, means for operating the same to retract it, a dogging device carried by said slide, means for shifting the position of said dogging device into its unlocked or locked position and a spring operating to advance the latch-slide, said spring being arranged to frictionally hold the dogging-slide in either of its operative positions.

5. In a lock, a plate, a latch-slide carried at the inner side thereof, a second plate and means for securing the same to the first-mentioned plate and adjusting said plates to and fro, a knob carried by each of said plates, a lock carried by each of said knobs, means of connection between each of said knobs and said latch-slide, a dogging device, independent roll-backs for operating said dogging device and means of connection between said roll-backs and said locks.

6. In a lock, two plates adjustable to and fro, a latch-slide carried by one of said plates, a knob carried by the same plate in turn carrying a roll-back coöperating with said slide, a knob carried by the other plate, a knob-shank projecting therefrom, a tubular telescopic coupling between said shank and said roll-back.

7. In a lock, a latch-slide, a dogging device carried by the slide and means comprising two independent alined spindles controllable from opposite sides of the door to operate said dogging device to check the movement of said slide.

8. In a lock, two plates adjustable to and fro, a latch-slide carried by one of said plates, a knob carried by the same plate in turn

carrying a roll-back coöperating with said slide, a knob carried by the other plate, a knob-shank projecting therefrom, a tubular telescopic coupling between said shank and said roll-back, a dogging device arranged to coöperate with said latch-slide to engage or disengage the same and independent key-controlled means carried by each of said knobs for operating said dogging device.

9. In a lock, two plates adjustable to and fro, a latch-slide carried by one of said plates, a knob carried by the same plate in turn carrying a roll-back coöperating with said slide, a knob carried by the other plate, a knob-shank projecting therefrom, a tubular telescopic coupling between said shank and said roll-back, a dogging device carried by said latch-slide and independent key-controlled means for operating said dogging device, said means being accessible from each side of the lock.

10. In a lock, a frame-plate arranged to bear against the outer surface of the door said plate being recessed on its inner surface to receive operating parts, a latch-slide and a roll-back located in said recess, a face-plate arranged to bear against the edge of the door and carried by said side plate, a second plate independent of said first-mentioned plate and said face-plate and arranged to be engaged upon the opposite side of the door, knobs carried by each of said plates said knobs being adjustably connected with each other and in turn being connected with said slide.

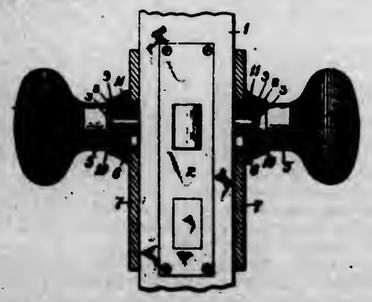
11. In a lock, a pair of escutcheon-plates adjustable to and fro, separate knobs carried by each of said plates and movable therewith, a latch-slide carried by one of said plates and means of connection between said latch-slide and each of said knobs, a dogging device arranged to check the movement of said slide and means on opposite sides of the lock for operating said dogging device one of said means comprising a spindle located concentrically with one of said knob-shanks and controllable independently of said knobs.

12. In a lock, two plates adjustable to and fro, a latch-slide carried by one of said plates, a knob carried by the same plate, a roll-back connected to said knob and coöperating with said slide, a knob carried by the other plate, a knob-shank carried thereby and projecting therefrom, and adjustable means of operative connection between the knob-shank and said latch-slide, whereby said second plate may be adjusted to and fro with said knob and operative connection maintained between both of said knobs and said latch mechanism.

13. In a lock, two plates adjustable to and fro, a latch-slide carried by one of said plates, a knob carried by the same plate, a roll-back operated by said knob and coöperating with said slide, a knob carried by the other plate and in alinement with the first-mentioned knob, a knob-shank projecting from said second knob, and a telescopic connection between the same and the latch-operating mechanism.

14. In a lock, two plates adjustable to and fro, a latch-slide carried by one of said plates, a knob carried by the same plate, a roll-back connected to said knob and coöperating with said slide, a knob carried by the other plate, a knob-shank carried thereby and projecting therefrom, and a telescopic connection between the knob-shank and said latch-slide, whereby said second plate may be adjusted to and fro with said knob and operative connection maintained between both of said knobs and said latch mechanism, and a lock carried by one of said knobs, said lock including a rotatable member and means of connection between said rotatable member and the latch-slide.

809,425. **LOCK AND LATCH FITTINGS.** CHARLES J. CALEY, New Britain, Conn., assignor to Russell & Erwin Manufacturing Company, New Britain, Conn., a Corporation of Connecticut. Filed Oct. 29, 1904. Serial No. 230,469.



Claim.—1. In lock and latch fittings, the combination of a spindle, knobs, with an antifriction device for one of said knobs comprising a ball race and retainer, a series of balls carried thereby and a conical bearing carried by said spindle and affording a longitudinal as well as vertical abutment.

2. A spindle-bearing comprising the combination of a plate forming a housing and support, a ball race and retainer, a series of balls carried therein, a knob-spindle and a conical bearing carried thereby and coacting with said balls for resisting longitudinal as well as vertical movement of said spindle, substantially as described.

3. In a spindle-bearing, the combination of a housing, a series of balls, a knob-spindle and a bearing member carried thereby and adapted to rotate therewith and having a convexly-curved surface for permitting compensation for angular displacement.

4. In a device of the character described, the combination of a thimble or rose-plate, a ball race and retainer secured therein, a series of balls carried in said retainer, a spindle, a knob and a conical bearing member for coacting with said balls.

5. In a device of the character described, the combination of a rose-plate or thimble, a ball race and retainer secured therein, a series of balls in said retainer, a yielding support for said retainer, a knob and a conical bearing for coacting with said parts for the purpose specified.

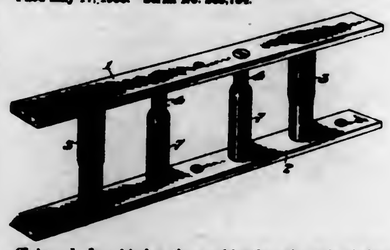
6. In a device of the character described, the combination of a rose-plate or thimble, a ball race and retainer secured therein, a yielding support therefor, a series of balls in said retainer, a knob and a conical bearing having a curved surface for compensation, substantially as described.

7. In a device of the character described, the combination of a spindle having a threaded portion on one end, a housing, a series of antifriction-balls located therein, a bearing carried by said spindle, and a knob and coupling affording means of connection with said threaded portion of said spindle, substantially as described and for the purpose specified.

8. In lock and latch mechanism, the combination of a thimble or rose-plate, a ball race and retainer arranged therein, a series of balls carried by said retainer, a knob, a spindle connected thereto, a conical bearing arranged to coact with said balls and affording a longitudinal as well as vertical abutment for said knob.

9. As an article of manufacture, a lock and latch fitting, comprising, a thimble or rose-plate adapted to be secured to a door and having a vertical inner shoulder, a combined ball race and retainer secured in said thimble or rose-plate, a series of balls contained therein but exposed outwardly and toward the axis for coöperation with a conical bearing, and a spring arranged between said shoulder and said combined retainer and ball-race, affording a yielding abutment therefor.

809,426. **BINDER.** FREDERICK A. CLEVELAND, New York, N. Y. Filed May 17, 1905. Serial No. 260,784.



Claim.—1. In a binder, the combination of a pair of clamping members, a post attached to one of said clamping members, an unattached pawl or dog carried by said post and fulcrumed therein and adapted to engage the inner surface of a casing, a casing secured to the other of said clamping members adapted to telescope over said post, substantially as described.

2. In a binder, the combination of a pair of clamping members, a post having a slot at the lower end thereof attached to one of said clamping members, an unattached pawl or dog carried by said post and fulcrumed therein and adapted to engage the inner surface of a casing, a casing secured to the other of said clamping members adapted to telescope over said post, substantially as described.

3. In a binder, the combination of a pair of clamping members, a post having a slot at the lower end thereof attached to one of said clamping members, an unattached pawl or dog carried by said post and fulcrumed therein in such a manner that the bottom of said slot forms a stop to limit the movement of said pawl or dog, a casing secured to the other of said clamping members adapted to telescope over said post, substantially as described.

4. In a binder, the combination of a pair of clamping members, a post attached to one of said clamping members, an unattached pawl or dog carried by said post and fulcrumed therein and adapted to engage the inner surface of a casing, a casing having a serrated inner surface secured to the other of said clamping members and adapted to telescope over said post, substantially as described.

5. In a binder, the combination of a pair of clamping members, a post attached to one of said clamping members, an unattached pawl or dog carried by said post and fulcrumed therein and adapted to engage the inner surface of a casing, a casing having a threaded inner surface secured to the other of said clamping members and adapted to telescope over said post, means for rotating said post in said casing, substantially as described.

6. In a binder, the combination of a pair of clamping members, a post having a chamber at the lower end thereof attached to one of said clamping members, an unattached pawl or dog carried by said post and fulcrumed therein and adapted to engage the inner surface of a casing, a casing secured to the other of said clamping members adapted to telescope over said post, substantially as described.

7. In a binder, the combination of a pair of clamping members, a post having a slot at the lower end thereof, said slot being partially closed by means of a stop member secured therein, an unattached pawl or dog carried by said post in said slot and fulcrumed against said stop member and adapted to engage the inner surface of a casing, a casing secured to the other of said clamping members adapted to telescope over said post, substantially as described.

8. In a binder, the combination of a pair of clamping members, a post attached to one of said clamping members, an unattached pawl or dog carried by said post and having one end thereof adapted to be fulcrumed therein and the other end thereof adapted to engage the inner surface of a casing, a casing secured to the other of said clamping members adapted to telescope over said post, substantially as described.

9. In a binder, the combination of a pair of clamping members, a post attached to one of said clamping members, an unattached pawl or dog carried by said post and having one end thereof curved to fulcrum therein and the other end thereof adapted to engage the inner surface of a casing, a casing secured to the other of said clamping members adapted to telescope over said post, substantially as described.

10. In a binder, the combination of a pair of clamping members, a post attached to one of said clamping members, an unattached pawl or dog carried by said post and having one end thereof formed on a circular arc to fulcrum therein and the other end thereof adapted to engage the inner surface of a casing, a casing secured to the other of said clamping members adapted to telescope over said post, substantially as described.

11. In a binder, the combination of a pair of clamping members, a post having a slot at the lower end thereof, said slot being partially closed by means of a stop member secured therein, a stop member having a portion thereof adapted to form a fulcrum for a pawl or dog, an unattached pawl or dog carried by said post in said slot and having one end thereof adapted to be fulcrumed against said stop member and the other end thereof adapted to engage the inner surface of a casing, a casing secured to the other of said clamping members adapted to telescope over said post, substantially as described.

12. In a binder, the combination of a pair of clamping members, a post having a slot at the lower end thereof, said slot being partially closed by means of a stop member secured therein, a stop member having a portion thereof curved to form a fulcrum for a pawl or dog, an unattached pawl or dog carried by said post in said slot and having one end thereof curved to adapt it to be fulcrumed against said stop member and the other end thereof adapted to engage the inner surface of a casing, a casing secured to the other of said clamping members adapted to telescope over said post, substantially as described.

13. In a binder, the combination of a pair of clamping members, a post having a slot at the lower end thereof, said slot being partially closed by means of a stop member secured therein, a stop member having a portion thereof formed on a circular arc to provide a fulcrum for a pawl or dog, an unattached pawl or dog carried by said post in said slot and having one end thereof formed on a circular arc to adapt it to be fulcrumed against said stop member and the other end thereof adapted to engage the inner surface of a casing, a casing secured to the other of said clamping members adapted to telescope over said post, substantially as described.

14. In a binder, the combination of a pair of clamping members, a post having a slot at the lower end thereof, said slot being partially closed by means of a stop member secured therein, a stop member having a portion thereof formed on a circular arc to provide a fulcrum for a pawl or dog, an unattached pawl or dog carried by said post in said slot and having one end thereof formed on a circular arc to adapt it to be fulcrumed against said stop member and having at the other end thereof a projection adapted to engage coöperating projections on the inner surface of the casing, a casing having projections from the inner surface thereof adapted to engage said projection on said pawl or dog, said casing being secured to the other of said clamping members and adapted to telescope over said post, substantially as described.

809,427. **BOTTLE-CLOSURE.** JOSEPH C. COMBS, Alexandria, Ind. Filed Dec. 10, 1904. Serial No. 237,504.

Claim.—1. In combination with a bottle, the neck 2 having the annular recess 10 formed at the mouth thereof, the resilient ring 11 seated in the recess 10, the disk 9 above the ring 11, a closure consisting of a tubular body closed at one end and receiving the neck therein, said closed end engaging the disk 9 and having a projection pressed outwardly therefrom and spaced from the disk 9 so as to be readily severed from the closed end of the tubular body, and an annulus coöperating with the tubular body to prevent displacement thereof.

2. In combination with a bottle or like necked receptacle, a closure comprising a tubular body receiving the neck, a second tubular member secured to the neck and preventing displacement of the first-mentioned tubular body, and resilient annuli between the neck and the tubular members aforesaid.

3. In combination with a bottle or like necked receptacle, a closure comprising a tubular body receiving the neck, a second tubular member secured to the neck and preventing displacement of the first-mentioned tubular body, resilient annuli between the neck and the tubular members aforesaid, and means upon the neck interlocking with the tubular member aforesaid.

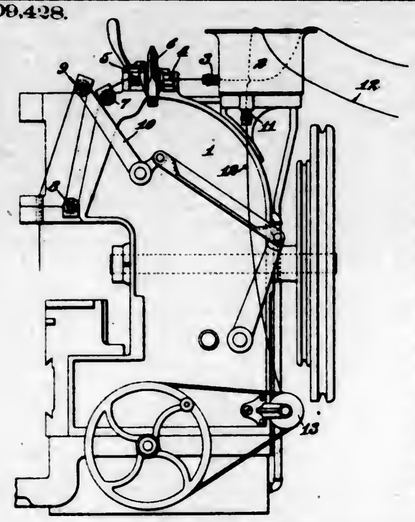
4. In combination with a bottle or like necked receptacle, a sectional closure comprising a tubular body receiving the neck and having a portion pressed therefrom to provide a projection adapted to be severed from said body, a second tubular member adapted to receive the first-mentioned tubular body and the neck, a resilient annulus between the neck and the tubular member, and projections extending from the tubular member and having interlocking connection with the neck.

5. In combination with a bottle or like necked receptacle, a ring surrounding said neck and secured thereto, said ring being provided with an outwardly-projecting flange, and a closure for the neck having a plurality of lugs or extending members provided with projections to engage over the flange of the ring aforesaid, whereby said closure is prevented from displacement.

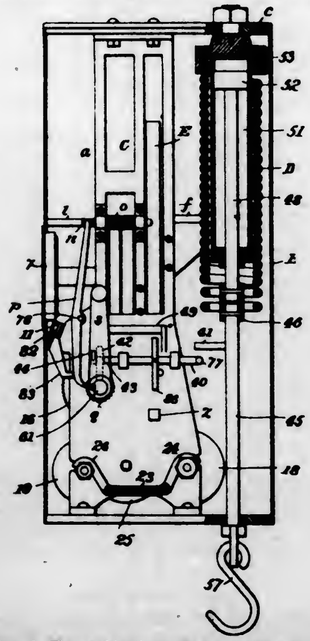
809,428. **WAX-POT FOR SEWING-MACHINES.** GEORGE L. CONCORAN and GEORGE A. DOSTER, St. Louis, Mo., assignors to Champion Shoe Machinery Company, St. Louis, Mo., a Corporation of Missouri. Filed Aug. 4, 1905. Serial No. 272,720.

Claim.—In a machine of the class described, mechanism for measuring and feeding a strand of thread, a wax-pot carried by the frame of the machine and having a thread-opening in its side wall alining with said thread measuring and feed mechanism, mechanism for winding thread onto a bobbin, and a thread-opening in the bottom of the wax-pot for receiving a second strand of thread that passes through the wax-pot and is wound onto the bobbin; substantially as described.

809,428.



809,429. AUTOMATIC RECORDING ICE-SCALE. CHARLES B. CRANE, Seattle, Wash. Filed May 2, 1905. Serial No. 258,429.



Claim.—1. The combination with the casing, printing-wheels, spring-supported rod and connections, and platen of a spring-scale, of a handle outside the casing, connections for operating the printing devices, two recording-strips, a cutter for cutting one of the strips, means for operating it from said handle, and means for delivering the cut portions outside the casing, substantially as set forth.

2. The combination in a spring-scale, of a casing, a helical spring suspended within the same, a rod connected with said spring and extending through the bottom of the casing, a ticket-printing mechanism including means whereby the type indicating the weight is shifted on the movement of the said rod and in proportion thereto, a handle outside the casing, connections whereby the printing mechanism may be actuated while the spring is distended, and a locking device whereby a second movement of the handle is prevented until the spring is again contracted, substantially as set forth.

3. The combination in a weighing-machine, of a suspended helical spring, a rod connected to the lower end of the spring and extending upward within the spring and provided with a piston, and a cylinder within said spring receiving said piston and constituting therewith a dash-pot, substantially as set forth.

4. The combination of the type-disk E, means for turning the same in proportion to the weight of an article to be weighed, said disk provided on its face with a series of tapering sockets, arranged in a circle, a slide having a pointed end adapted to said sockets, means for moving the slide toward the disk to bring each type into proper printing position, an operating-handle, and means for preventing the movement of the latter until the slide is in position in one of the sockets, substantially as set forth.

5. The combination with a type-disk, slide *l*, platen, and operating-handle *s*, of a ratchet *g* connected to said handle, a lever *p* engaging said ratchet at one end, and a pin on the slide engaging the other end of the lever, substantially as set forth.

6. The combination in a weighing-machine, of a suspended spring, a rod suspended therefrom, printing mechanism including a type-disk connected to be turned in proportion to the extent to which the spring is distended, an operating-handle, and means for preventing the operation of the handle until the spring is distended and for restraining the further movement of the handle until the spring again contracts, substantially as set forth.

7. The combination with the spring and rod 45, printing mechanism and operating-handle, of a rock-shaft provided with studs for limiting the movement of the handle and with a projecting arm, and a pin upon the rod 45 for engaging said arm, substantially as set forth.

8. The combination with the spring, rod 45 and its pin 41, of printing devices, an operating-handle, an arm 42 connected to be carried therewith, and a rock-shaft 40 provided with studs 43, 44 at an angle to each other and with an arm 77 in position to be struck by the pin 41, substantially as set forth.

9. The combination with the spring-balance of a weighing-machine, of a printing-disk connected to be moved in proportion to the distension of the spring, dating-disks, means for adjusting the same, a platen beneath the said disks, an operating-handle, means for operating the platen on the turning of said handle, and means for locking the handle until the parts are in position for printing, substantially as set forth.

10. The combination with the type-carrying devices, a movable bar provided with means for supporting a body to be weighed, and connections for operating the type-carriers from said bar, of a movable platen, a shaft, a handle for operating the same, a cam arranged to lift the platen on the turning of the shaft, and means for locking the handle until the type-carriers are in place, substantially as set forth.

11. The combination with the type-carrying devices, a movable bar provided with means for supporting a body to be weighed, and connections for operating the type-carriers from said bar, of a movable platen, a shaft, a handle for operating the same, a cam arranged to lift the platen on the turning of the shaft, a hammer, and means for operating the hammer to carry the platen percussively toward the type after the platen is raised, substantially as set forth.

12. The combination with the type-carrying devices and platen, a movable bar provided with means for supporting a body to be weighed, and connections for operating the type-carriers from said bar, of a cam, connections for raising the platen, a hammer for striking the platen, and means for withdrawing and releasing the said hammer after the platen is raised, substantially as set forth.

13. The combination with the type-carrying devices and platen, a movable bar provided with means for supporting a body to be weighed, and connections for operating the type-carriers from said bar, of a shaft, a cam thereon for raising the platen, a hammer and spring-support therefor, and a pin upon the said shaft arranged to engage and release said hammer, substantially as set forth.

14. The combination with the type-carrying devices and platen, a movable bar provided with means for supporting a body to be weighed, and connections for operating the type-carriers from said bar, of means for carrying a plurality of strips between the platen and type, a cutter for cutting one of the strips, an operating-handle, means whereby the said strips are carried beneath the type, and the cutter operated and the platen carried to and from the type upon the movement of the handle, a casing inclosing the parts, and means for delivering the cut portion of the strip outside the casing, substantially as set forth.

15. The combination with the type-carriers and platen, a movable bar provided with means for supporting a body to be weighed, and connections for operating the type-carriers from said bar, of means for feeding two strips across the platen, a cutter, means for actuating the same to cut sections from one of the strips, and a spool and means for turning it to roll up the other strip, substantially as set forth.

16. The combination with the type-carriers, and platen, a movable bar provided with means for supporting a body to be weighed, and connections for operating the type-carriers from said bar, of means for feeding two strips across the platen, a cutter, means for actuating the same to cut sections from one of the strips, and a spool and a motor for turning it to roll up the other strip, substantially as set forth.

17. The combination with the type-carriers and platen, a movable bar provided with means for supporting a body to be weighed, and connections for operating the type-carriers from said bar, of means for feeding two strips across the platen, a cutter, means for actuating the same to cut sections from one of the strips, a spool, and a spring-actuated drum to turn the same to roll up the other strip, substantially as set forth.

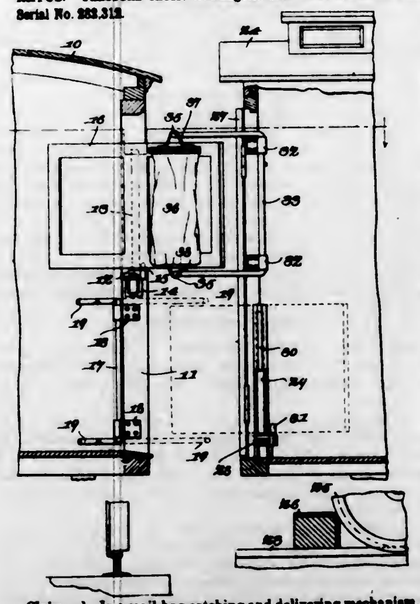
18. The combination with the type-carrying devices and platen, a movable bar provided with means for supporting a body to be weighed, and connections for operating the type-carriers from said bar, of means for carrying superposed strips across the face of the platen, and means for guiding a printing-ribbon transversely across the face of the platen over one of the strips and back over the other, substantially as set forth.

19. The combination with the type-carrying devices and platen, a movable bar provided with means for supporting a body to by weighed, and connections for operating the type-carriers from said bar, of means for feeding a strip across the face of the platen, a printing-ribbon, spools, and a guide-roll arranged to direct the said ribbon across the face of the platen at right angles to the direction of the paper strip, substantially as set forth.

20. The combination with the spring, shaft, type-disk and spring-blade *i*, of a bearing-pin *j* adjustable upon said disk, substantially as set forth.

21. The combination with the frame having slots for the reception of shafts, of oppositely-arranged spools, two hooked levers engaging said shafts, and a spring connecting the ends of both levers, substantially as set forth.

809,430. MAIL-BAG RECEIVING AND DELIVERING APPARATUS. THEODORE CROSS, Washington, Ind. Filed Oct. 11, 1905. Serial No. 282,312.



Claim.—1. In a mail-bag catching and delivering mechanism, a plate having means applied intermediate thereof for swinging in a car-doorway, a supporting structure movable toward and away from the path of the car, and a mail-bag-supporting means attached to said structure.

2. In a mail-bag catching and delivering mechanism, a plate having means applied intermediate thereof for swinging in a car-doorway, guide-tracks arranged at right angles to the line of movement of the car, a supporting structure movable upon said tracks, and mail-bag-supporting means carried by said structure.

3. The combination with a railway-car of a plate having means applied intermediate thereof for swinging in the doorway of said car, means for suspending a mail-bag from said car, guide-tracks arranged at right angles to the line of movement of the cars, a supporting structure movable upon said guide-tracks, a plate having means applied intermediate thereof for swinging in said structure, and means for suspending a mail-bag from said structure.

4. The combination with a railway-car of a plate having means applied intermediate thereof for swinging in the doorway of said car, means for suspending a mail-bag and movably connected to the car and swinging into and projecting from the same, means for suspending a mail-bag in the path of said plate when projected, and means for removing a mail-bag from said suspending means when projected.

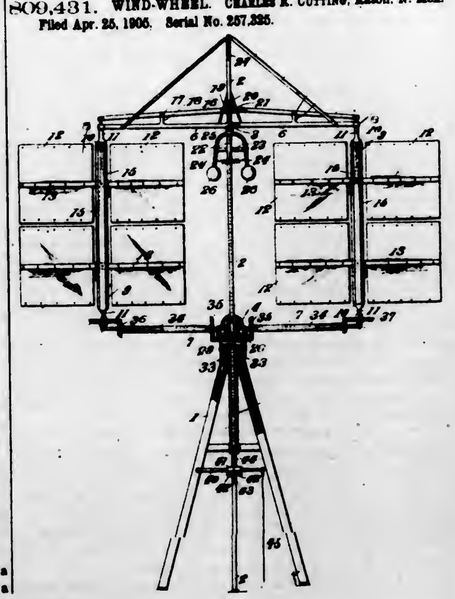
5. The combination with a railway-car of a plate having means applied intermediate thereof for swinging in the doorway of said car, means for suspending a mail-bag and movably connected to the car and swinging into and projecting from the same, a supporting structure movable toward and away from the line of movement of the car, a plate having means applied intermediate thereof for swinging in said structure, means for suspending a mail-bag and movably connected to said structure and swinging into and projecting from the same.

6. The combination with a car of a bar disposed transversely of its doorway-opening, a plate mounted intermediate thereof for swinging upon said bar, and means for suspending a mail-bag in the path of said plate when projected.

7. The combination with a car of a bar disposed transversely of its doorway-opening and provided with a stop member, a plate pivoted intermediately thereof to said bar and limited in its movement by said stop member, and means for suspending a mail-bag in the path of said plate when projected.

8. The combination with a railway-car of a mail-bag-suspending member consisting of a U-shaped bar mounted to swing through the doorway-opening of the car and with oppositely-extending suspension-fingers at the terminals of its arms.

809,431. WIND-WHEEL. CHARLES R. CUTTING, Raton, N. Mex. Filed Apr. 25, 1905. Serial No. 257,335.



Claim.—1. In a wind-wheel, the combination of a wheel-shaft, sets of blades rotatable with said shaft, the blades of each set being movable about horizontal axes, means for feathering the blades, and means for causing the blades of each set to move in opposite directions in feathering about the horizontal axes thereof.

2. In a wind-wheel, the combination of a wheel-shaft, sets of blades rotatable with said shaft, each set of blades being movable about a vertical axis, means for causing each set of blades to make a half-revolution about its vertical axis in one revolution of the wheel, the blades of each set of blades being movable about horizontal axes also, a governor for feathering the blades about their horizontal axes, said governor embodying governor-levers, and independent connections between the governor-levers and the blades of each set aforesaid whereby said blades of each set are caused to move in opposite directions in feathering about the horizontal axes thereof.

3. In a wind-wheel, the combination of a wheel-shaft, a plurality of arms projected from said shaft, vertical frames supported by said arms, blades movable about horizontal axes and carried by the frames aforesaid, and a governor connected with said blades so as to cause the same to move in opposite directions in throwing the latter out of the wind.

809,432. **ADJUSTABLE HOLDER FOR DRAWING MODELS AND THE LIKE.** GUSTAV J. DIRRSCHERBL, Dresden-Plauschen, Germany. Filed Apr. 16, 1904. Serial No. 203,515.

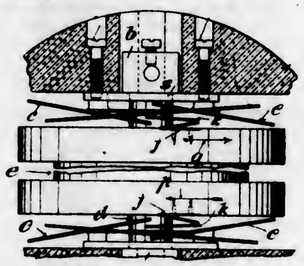
Claim.—1. An adjustable holder for drawing models, comprising a horizontal disk provided with a scale, a vertical disk provided with a scale, pivotally mounted at the center of said horizontal disk, and a holding device pivotally secured to the said vertical disk with capability of turning in a vertical plane, substantially as described.

2. An adjustable holder for drawing models comprising a horizontal disk *d*, a vertical disk *f* pivotally mounted at the center of said horizontal disk *d*, a second horizontal disk *i* pivotally secured to the said vertical disk *f*, a second vertical disk *l* pivotally mounted at the center of said horizontal disk *i*, all the said disks *d f i l* being provided with scales, and a holding device pivotally secured to the said disk *l* with capability of turning in a vertical plane, all substantially as described.

809,433. **ROTARY ELECTRIC SWITCH.** JOHN DUDDELL, Fallsworth, Manchester, England. Filed Mar. 15, 1905. Serial No. 250,226.

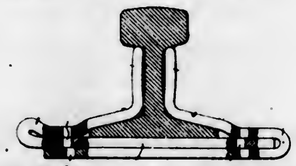
Claim.—1. A rotary switch comprising a spring-drum, a support for the same, contacts on each of said parts and means for permitting said contacts to engage each other when the drum rotates in one direction and for preventing engagement when the drum rotates in the other direction, substantially as described.

2. A rotary switch comprising a spring-drum, a support therefor, a contact on each of said parts, and a shield of non-conducting material carried by said drum said shield covering the contact on the drum and being set at an incline to said drum so that when the drum is rotated in one direction said shield will engage with a contact on the support and force said contact into engagement with the drum-contact, while when the drum is rotated in the opposite direction said shield will prevent engagement of the contacts, substantially as described.



3. A rotary switch consisting of a body of non-conducting material, a spring-drum mounted to rotate therein, a current-consuming apparatus, wires connecting said apparatus with the drum, fixed contact-plates carried by the body, an electric circuit connected to said plates, contact-plates connected to the drum, and means for allowing the side plates to engage with each other on the rotation of the drum in one direction and for preventing the engagement of said plates on the rotation of the drum in the other direction, substantially as described.

809,434. **RAIL-JOINT CHAIR.** AURELIUS M. EWING, Seattle, Wash. Filed Sept. 11, 1905. Serial No. 277,942.



Claim.—1. A rail-joint comprising superimposed plates adapted to be interposed between the rail and a tie and each extending laterally upon both sides of the rail, the upper plate being folded upon itself for engagement with the base-flanges upon one side and the lower plate folded over and embracing one extended side of the upper plate and for engagement with the base-flange of the opposite side.

2. A rail-joint chair comprising superimposed plates adapted to be interposed between the rail and a tie and each extending laterally upon both sides of the rail, the upper plate being folded upon itself for engagement with the base-flanges upon one side and the lower folded over and embracing one extended side of the upper plate and for engagement with the base-flange of the opposite side, the said extended plates being each provided upon both sides with spike-receiving openings normally out of alinement but arranged to be forced to register and the plates to grip the rail by the driving of a fastening.

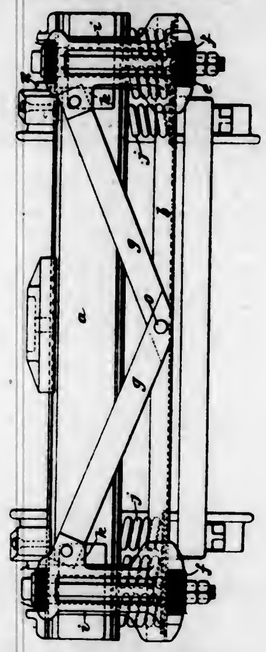
809,435. **RAILWAY-CAR TRUCK.** WALTER PERRIN, South Milwaukee, Wis., assignor to The Bucyrus Company, South Milwaukee, Wis., a Corporation of Wisconsin. Filed Apr. 14, 1905. Serial No. 255,557.

Claim.—1. A railway-car truck, comprising a bolster, upper and lower arch-bars, bolster-columns, a spring-plank secured to the lower arch-bars, means connecting the upper arch-bars to prevent independent lateral movement thereof, and diagonal braces attached at their ends to the upper ends of the bolster-columns and the spring-plank, respectively.

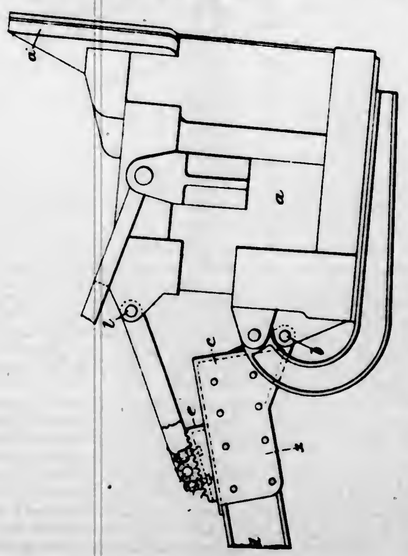
2. A railway-car truck, comprising a bolster, upper and lower arch-bars, bolster-columns, a spring-plank secured to the lower arch-bars, lugs on the bolster ends engaging the upper arch-bars to prevent independent lateral movement of said arch-bars, and diagonal braces attached at their ends to the upper ends of the bolster-columns and the spring-plank, respectively.

3. A railway-car truck, comprising a bolster, upper and lower

arch-bars, bolster-columns, a spring-plank secured to the lower arch-bars, lugs on the bolster ends engaging the upper arch-bars to prevent independent lateral movement of said arch-bars, and diagonal braces attached to the top of the bolster-columns by the through-bolts and to the spring-plank, respectively.



809,436. **DIPPER FOR DREDGES, EXCAVATORS, AND THE LIKE.** WALTER PERRIN, South Milwaukee, Wis., assignor to The Bucyrus Company, South Milwaukee, Wis., a Corporation of Wisconsin. Filed Apr. 14, 1905. Serial No. 255,558.

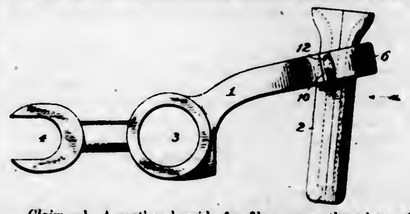


Claim.—1. The combination of a dredge-dipper, a handle to which said dipper is hinged, a brace pivotally connected to the dipper, a journal-bearing in which the other end of said brace is pivoted, and means for adjustably securing said bearing to the dipper-handle; whereby the cutting angle of the dipper may be varied.

2. The combination of a dredge-dipper, a handle to which said dipper is hinged, a brace pivotally connected to the dipper, a serrated lug on the handle, a journal-bearing in which the other end of the brace is pivoted and having serrations meshing with those on the lug, and means for adjustably securing said bearing to the lug.

3. The combination of a dredge-dipper, a handle to which said dipper is hinged, a brace pivotally connected to the dipper, a serrated lug on the handle, a journal-bearing in which the other end of the brace is pivoted and having serrations meshing with those on the lug, and bolts carried by said bearing and engaging a slot in said lug to adjustably secure said bearing to the lug.

809,437. **THREAD-GUIDE.** DAVID C. FINNEY, Huntsville, Ala. Filed July 29, 1903. Renewed Dec. 7, 1905. Serial No. 290,783.



Claim.—1. A sectional guide for fiber, yarn, thread or other material having a flaring end, one section thereof being provided at its flaring end with means for engaging the interior of the flaring end of another section, whereby said sections are held in proper relation to each other.

2. A guide for fiber, yarn, thread or other material, comprising longitudinally-disposed separable sections and having a flaring end, one section thereof being provided at its flaring end with means for engaging the interior of the flaring end of another section, whereby said sections are held in proper relation to each other.

3. A sectional guide for yarn, fiber, thread or other material having a flaring end, one section thereof being provided at its flaring end with means for engaging recesses in the flaring end of another section, substantially as described.

4. A guide for yarn, fiber, thread or other material, comprising longitudinally-disposed separable sections and having a flaring end, one section being provided at its flaring end with means for engaging recesses in the flaring end of another section, substantially as described.

5. A sectional guide for yarn, fiber, thread or other material having a flaring end, one section thereof being provided at its flaring end with projecting leaves for engaging the flaring end of another section, substantially as described.

6. A guide for yarn, fiber, thread or other material, comprising longitudinally-disposed separable sections and having a flaring end, one section being provided at its flaring end with projecting leaves for engaging the flaring end of another section, substantially as described.

7. A sectional guide for yarn, fiber, thread or other material having a flaring end, one section thereof being provided at its flaring end with projecting leaves for engaging recesses in the flaring end of another section, substantially as described.

8. A guide for yarn, fiber, thread or other material, comprising longitudinally-disposed separable sections and having a flaring end, one section being provided at its flaring end with projecting leaves for engaging recesses in the flaring end of another section, substantially as described.

9. A hollow sectional guide for fiber, yarn, thread or other material, one section thereof having fingers near one end arranged to engage the interior of the corresponding end of another section, substantially as described.

10. A hollow guide for fiber, yarn, thread or other material, comprising longitudinally-disposed separable sections, one section thereof having fingers near one end arranged to engage the interior of the corresponding end of another section, substantially as described.

11. A hollow sectional guide for fiber, yarn, thread or other material, one section thereof having wedge-shaped fingers near one end

arranged to engage the interior of the corresponding end of another section, substantially as described.

12. A hollow guide for fiber, yarn, thread or other material, comprising longitudinally-disposed separable sections, one section thereof having wedge-shaped fingers near one end arranged to engage the interior of the corresponding end of another section, substantially as described.

13. A hollow sectional guide for fiber, yarn, thread or other material, one section thereof having near one end an inclined surface arranged to seat on an inclined surface near the corresponding end of another section, substantially as described.

14. A hollow guide for fiber, yarn, thread or other material, comprising longitudinally-disposed separable sections, one section thereof having near one end an inclined surface arranged to seat on an inclined surface near the corresponding end of another section, substantially as described.

15. A sectional guide for fiber, yarn, thread or other material, one section thereof being provided with an inclined surface and projecting fingers, and another section opposite said first-mentioned section thereof being provided with an inclined surface and recesses arranged to seat the surface and fingers of its opposite section, substantially as described.

16. A guide for fiber, yarn, thread or other material, comprising longitudinally-disposed separable sections, one section being provided with an inclined surface and projecting fingers, and another section opposite said first-mentioned section being provided with an inclined surface and recesses arranged to seat the surface and fingers of its opposite section, substantially as described.

17. A sectional guide for fiber, yarn, thread or other material, having a separable end closure therein provided with an aperture, substantially as described.

18. A guide for fiber, yarn, thread or other material, comprising longitudinally-disposed separable sections, and having a separable end closure therein provided with an aperture, substantially as described.

19. A sectional guide for fiber, yarn, thread or other material, having in one end a longitudinally-perforated closure comprising separable sections, substantially as described.

20. A guide for fiber, yarn, thread or other material, comprising longitudinally-disposed separable sections, and having in one end a longitudinally-perforated closure comprising separable sections.

21. A sectional guide for fiber, yarn, thread or other material, having in one end a longitudinally-perforated closure, said closure comprising sections separable along a line at an angle to said perforation, substantially as described.

22. A guide for fiber, yarn, thread or other material, comprising longitudinally-disposed separable sections, and having in one end a longitudinally-perforated closure, said closure comprising sections separable along a line at an angle to said perforation, substantially as described.

23. The combination of a sectional guide for fiber, yarn, thread or other material, and a holder therefor comprising an eye having a swinging arm for opening and closing said eye, and means for securing said arm in closed position and engaging the guide, substantially as described.

24. The combination of a sectional guide for fiber, yarn, thread or other material, and a holder therefor comprising an eye having a swinging arm for opening and closing said eye, and means on said arm for securing it in closed position and engaging the guide, substantially as described.

25. The combination of a sectional guide for fiber, yarn, thread or other material, and a holder therefor comprising an eye having a swinging arm for opening and closing said eye, and a set-screw for securing said arm in closed position and engaging the guide, substantially as described.

26. The combination of a sectional guide for fiber, yarn, thread or other material, and a holder therefor comprising an eye having a swinging arm for opening and closing said eye, and a set-screw on said arm for securing it in closed position and engaging the guide, substantially as described.

27. The combination of a sectional guide for fiber, yarn, thread or other material, and a holder therefor comprising an eye having a swinging arm hung by a hinge-joint to the main portion of said holder for opening and closing the eye, and means for securing said arm in closed position and engaging the guide, substantially as described.

28. The combination of a sectional guide for fiber, yarn, thread or other material, and a holder therefor comprising an eye having a swinging arm hung by a hinge-joint to the main portion of said holder for opening and closing the eye, and means on said arm for securing it in closed position and engaging the guide, substantially as described.

29. The combination of a sectional guide for fiber, yarn, thread or other material, and a holder therefor comprising an eye having a swinging arm hung by a hinge-joint to the main portion of said holder for opening and closing the eye, and a set-screw for securing said arm in closed position and engaging the guide, substantially as described.

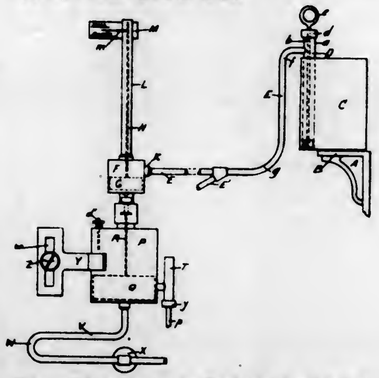
30. The combination of a sectional guide for fiber, yarn, thread or other material, and a holder therefor comprising an eye having a swinging arm hung by a hinge-joint to the main portion of said holder for opening and closing the eye, and a set-screw on said arm for securing it in closed position and engaging the guide, substantially as described.

31. The combination of a sectional guide for fiber, yarn, thread or other material, and a holder therefor, said holder having means whereby it can be released from its actuating means, and comprising means for simultaneously releasing said guide from said holder and the material passing therethrough, substantially as described.

32. The combination of a sectional guide for fiber, yarn, thread or other material, and a holder therefor, said holder having means whereby it can be released from its actuating means, and comprising an eye having a swinging arm for opening and closing said eye, and means for securing said eye in closed position and engaging the guide, substantially as described.

33. The combination of a sectional guide for fiber, yarn, thread or other material, one section thereof being provided with an inclined surface and projecting fingers, and another section thereof opposite said first-mentioned section being provided with an inclined surface and recesses arranged to seat the surface and fingers of its opposite section; and a holder for said guide comprising an eye having a swinging arm hung by a hinge-joint to the main portion of said holder for opening and closing said eye, and a set-screw on said arm for securing it in closed position and engaging the guide, substantially as described.

809,438. **MECHANISM FOR AUTOMATICALLY DISTRIBUTING LIQUID FUEL.** HENRI GALOPIN, Melbourne, Victoria, Australia. Filed May 19, 1905. Serial No. 261,220.



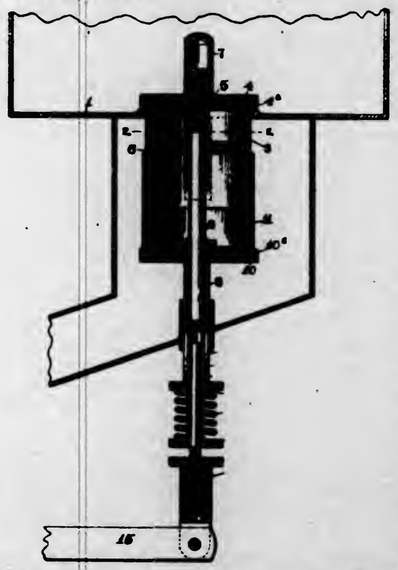
Claim.—1. In mechanism for distributing liquid fuel, in combination a chamber, containing a float, such float being adjustably weighted and having a vertical spindle contacting with a vertically-moving valve, operating against the orifice of a vertical inverted conical nozzle, and arranged to shut off the flow through such nozzle when said chamber has received a predetermined charge of such liquid, and a T-shaped pipe containing an overflow-pipe capable of vertical adjustment, substantially as and for the purposes herein described.

2. In mechanism for distributing liquid fuel, in combination, a chamber, containing a float, such float being adjustably weighted and having a vertical spindle contacting with a vertically-moving valve, operating against the orifice of a vertical inverted conical nozzle, and arranged to shut off the flow through such nozzle when said chamber has received a predetermined charge of such liquid, a T-shaped pipe containing an overflow-pipe capable of vertical adjustment, also a registering mechanism comprising a chamber containing a float with vertical spindle carrying a pointer at its upper extremity, and moving within a vertical tube carrying an index-plate, substantially as and for the purposes herein described.

3. In mechanism for distributing liquid fuel in combination a chamber, containing a float, such float being adjustably weighted and having a vertical spindle contacting with a vertically-moving valve, operating against the orifice of a vertical inverted conical nozzle, and arranged to shut off the flow through such nozzle when said chamber has received a predetermined charge of such liquid, a T-shaped pipe containing an overflow-pipe capable of vertical adjustment, also a supply-pipe with a siphon-bend at its inlet end having attached a pump comprising a pump-barrel, a plunger, a plunger-rod, a gland and a handle substantially as and for the purposes herein described.

4. In mechanism for distributing liquid fuel, in combination, a chamber containing a float, such float being adjustably weighted and having a vertical spindle contacting with a vertically-moving valve, operating against the orifice of a vertical inverted conical nozzle, and arranged to shut off the flow through such nozzle when said chamber has received a predetermined charge of such liquid, a T-shaped pipe containing an overflow-pipe capable of vertical adjustment, a registering mechanism comprising a chamber containing a float with vertical spindle carrying a pointer at its upper extremity, and moving within a vertical tube carrying an index-plate, and a supply-pipe with a siphon-bend at its inlet end having attached a pump comprising a pump-barrel, a plunger, a plunger-rod, a gland and a handle substantially as and for the purposes herein described.

809,439. **MEASURING-VALVE MECHANISM.** RUDOLPH W. GOSS, St. Louis, Mo., assignor to United States Fiber Stopper Company, St. Louis, Mo., a Corporation of South Dakota. Filed Jan. 23, 1905. Serial No. 242,189.



Claim.—1. In a measuring-valve mechanism, the combination with a measuring-chamber comprising telescopic sections, a tank to which one of the sections is rigidly secured, the other section being slidable on the rigid section, of valves without an interposed spring between them and being adapted to be moved longitudinally of said sections, one of said valves being adapted to be seated on the edge of the wall of the rigid section, and the other on the edge of the wall of the movable section, and a resiliently-controlled means for the valves and common to both of them for alternately opening and closing said valves; substantially as described.

2. In a measuring-valve mechanism, the combination with a tank, of a measuring-chamber having two parts, one of which is slidable on the other, and one of said parts being rigid with the tank, of valves without an interposed spring between them, said valves controlling the inlet and exit openings to and from said chamber, devices connected to said valves, and an expansible spring coöperating with said devices and whose energy is exerted to normally seat said valves; substantially as described.

3. In a measuring-valve mechanism, the combination with a casing including an extensible chamber comprising two parts, one of which is movable within the other, of operable valves in the ends of the casing for controlling the inlet and discharge openings to and from said chamber and adapted to be moved longitudinally thereof, means for adjusting said valves to accommodate them to the movement of the movable part of the chamber, said adjusting means also serving as operating means for said valves; substantially as described.

4. In a measuring-valve mechanism, the combination with a measuring-chamber, of valves for controlling the inlet and exit openings to and from said chamber, a rod on one of said valves having a flanged end, a sleeve on the other of said valves having a flanged end, said rod passing through said sleeve, and a spring interposed between the flanged ends of said rod and sleeve; substantially as described.

5. In a measuring-valve mechanism, the combination with a measuring-chamber, of a valve for closing the upper end of said chamber, a rod on said valve, a valve for closing the lower end of said chamber, a sleeve on said lower valve, through which sleeve said rod passes, the lower end of said rod being hollow, said rod and said sleeve being slotted, a rod 13 fitting in the hollow portion of the first-mentioned rod and having a cross-pin engaging slots in said first-mentioned rod and sleeve, and a spring coöperating with said first-mentioned rod and said sleeve; substantially as described.

6. In a measuring-valve mechanism, the combination with a measuring-chamber, of valves for controlling the inlet and outlet openings to and from said chamber, slotted members connected to said valves respectively, and a key passing through the slots of said members whereby when said key is moved in one direction it raises one of said valves from its seat, and when said key is moved in the opposite direction it moves the other of said valves from its seat; substantially as described.

7. In a measuring-valve mechanism, the combination with a measuring-chamber, of valves for controlling the inlet and outlet openings to and from said chamber, slotted members connected to said valves respectively, a key passing through the slots of said members whereby when said key is moved in one direction it raises one of said valves from its seat, and when said key is moved in the opposite direction it moves the other of said valves from its seat, and a spring for holding either of said valves to its seat while the other of said valves is unseated; substantially as described.

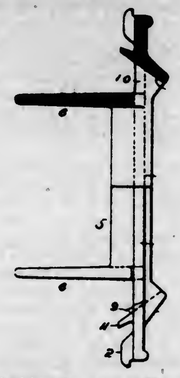
8. In a measuring-valve mechanism, the combination with the walls of a measuring-chamber, said walls being provided with valve-seats, one of said seats being fixed and the other movable, of means for adjusting the walls carrying the movable seat, whereby the cubical capacity of the chamber is changed, valves for coöperating with said seats, common means for operating said valves alternately, a compensating connection between one of said valves and said operating mechanism, and an adjusting mechanism between the other of said valves and said operating mechanism, whereby said last-mentioned valve may be adjusted to accommodate the changed position of its coöperating seat; substantially as described.

9. In a measuring-valve mechanism, the combination with telescoping walls forming a measuring-chamber, said walls having valve-seats at their ends, means for adjusting one wall with relation to the other whereby the cubical capacity of said chamber is changed, valves coöperating with said seats, common means for alternately opening and closing said valves, means for accommodating the valves in the changed position of the telescoping walls, said last-mentioned means operating independently of the valve-operating mechanism, whereby the same opening movement is imparted to both valves irrespective of the adjusted position of their coöperating seats; substantially as described.

10. In a measuring-valve mechanism, the combination with a fixed cylinder having a valve-seat at its upper end, a valve coöperating with said seat, means for holding said valve against rotation, a threaded rod engaging said seat, a telescoping cylinder coöperating with said first-mentioned cylinder, a valve which is seated against the lower end of said telescoping cylinder, means coöperating with both of said valves to move them from their seats alternately, a spring for moving said valves to seating position and holding them seated, means for adjusting the position of the telescoping cylinder, means for adjusting the position of the valve which coöperates with said telescoping cylinder to accommodate said valve to the different positions of said cylinder, said adjusting mechanism being independent of the valve-operating mechanism and includ-

ing the rod having threaded engagement with the valve seated on the upper end of the fixed cylinder, which threaded engagement constitutes a compensating mechanism for permitting said adjustment without disturbing the relation of said valve to its fixed seat; substantially as described.

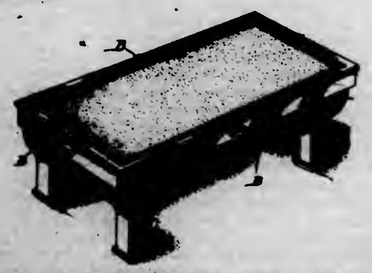
809,440. FEED-BOX FOR CANE-MILLS. JOHN P. GOLDEN, Columbus, Ga. Filed Apr. 3, 1905. Serial No. 253,417.



Claim.—1. A feed-box for a cane-mill having a feed-opening and a slot below the lower face of the feed-opening, flanges projecting inwardly from the inner face of the box said flanges having curved edges to conform to the curvature of the rolls of the mill, and an enlargement on the front face of the feed-box and having an inclined upper face alining with the lower wall of said slot.

2. A feed-box for cane-mills, having a slot near each end, outwardly-projecting drip-cups communicating with said slots, said feed-box having a feed-opening common to both slots and drip-cups, and flanges projecting inwardly at the upper and lower ends of said feed-opening.

809,441. CIGAR-HOLDER FOR BILLIARD AND POOL TABLES. ELBERT B. HAMES, Winthrop Harbor, Ill. Filed Dec. 27, 1904. Serial No. 238,594.

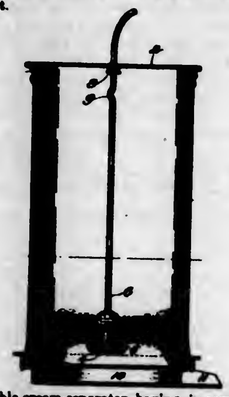


Claim.—1. A cigar-holder for billiard-tables and the like, consisting of a rest for holding the cigar, a rear vertical wall, and a forward extension at the upper end of said wall projecting horizontally beyond the front edge of said rest, said parts being apertured to receive holding-screws.

2. A cigar-holder for billiard-tables and the like, consisting of a rest for holding the cigar, a rear vertical wall, a forward extension at the upper end of said wall projecting horizontally beyond the front edge of said rest and then bent upwardly and then rearwardly to embrace the rail of the billiard-table, said parts being apertured to receive holding-screws.

809,442. CREAM-SEPARATOR. JOHN W. HINSLEY, Watertown, Minn. Filed July 15, 1905. Serial No. 269,618.

Claim.—1. A portable cream-separator, having, in combination, a body having its lower end shaped to form a base to support the body firmly in upright position and provided with a vent in the bottom, a stopper for closing the vent, and means connected with the stopper and extending to the top of the body for loosening the stopper to open the vent.



2. A portable cream-separator, having, in combination, a body having its lower end shaped to form a base to support the body firmly in upright position and provided with a vent centrally located in the bottom thereof, a cover arranged to be secured to the top of the body by a rotary movement and provided with a centrally-disposed opening, a stopper for the vent, and a rod secured to the stopper and passing loosely through the opening in the cover.

3. A portable cream-separator, having, in combination, a body with a vent in the bottom thereof, a cover provided with an opening, a stopper for the vent, and a rod secured to the stopper and passing through the opening in the cover, the rod being provided with an offset to engage the cover and prevent entire removal of the stopper from the vent when the cover is in place.

4. A portable cream-separator, having, in combination, a body with a vent in the bottom, means for opening and closing the vent, and a pan, for receiving the liquid discharged through the vent, provided with a shoulder for supporting the body above the bottom of the pan, and with a discharging-nose.

5. A portable cream-separator, having, in combination, a glass body having its lower end shaped to form a base to support the body firmly in upright position and provided with a vent in the bottom and a rubber stopper for closing the vent.

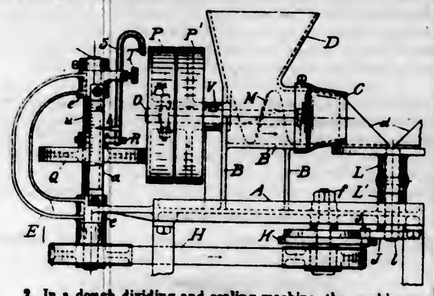
6. A portable cream-separator, having, in combination, a body having its lower end shaped to form a base to support the body firmly in upright position and provided with a vent in the bottom, a stopper for closing the vent, and means connected with the stopper for loosening the stopper to open the vent.

7. A portable cream-separator having, in combination, a body with a vent in the bottom thereof, a cover provided with an opening, a stopper for the vent and a rod secured to the stopper and passing through the opening in the cover, the rod being provided with means to engage the cover and prevent entire removal of the stopper from the vent when the cover is in place.

8. A portable cream-separator, having, in combination, a body with a vent in the bottom thereof, means for opening and closing the vent, and a pan for receiving the liquid discharged through the vent, constructed to receive the lower portion of the body and provided with means to support the body above the bottom of the pan.

809,443. DOUGH DIVIDING AND SCALING MACHINE. ROBERT HOMBRAGH, Jr., and WILLIAM LEITH, Joliet, Ill. Filed Aug. 24, 1904. Serial No. 223,022.

Claim.—1. In a dough dividing and scaling machine, the combination with a receptacle for dough having an outlet at one end for the passage of dough and having a spiral conveyer and conveyer-shaft, mounted on suitable bearings, of a power-pulley mounted on said shaft, of a frictional wheel in peripheral contact with the face of said power-pulley, a fixed shaft on which said frictional wheel is adjustably mounted, a dough cutter or divider, consisting of a horizontally and intermittently rotating table mounted on a vertical shaft, and having radially-arranged cutting knives or wires, in such a position as to sever from the mass of dough issuing from the said receptacle, predetermined weights and quantities of dough, means for communicating intermittent motion to said table from and through the medium of said frictional wheel, an index or pointer carried by said frictional wheel, a graduated scale-plate adjacent to said index, and means for adjusting said frictional wheel, radially with relation to the said power-pulley, whereby the speed of the frictional wheel may be varied, the desired weight of portions of dough indicated, and the corresponding portions of dough severed from the mass, all substantially as set forth.



2. In a dough dividing and scaling machine, the combination with intermittently-operating cutters, mounted on a vertical axis and adapted to travel horizontally and to cut portions of dough from a constantly-feeding mass, of means for automatically regulating the amount of dough cut at each motion of the cutters, and means for indicating the weight of each portion of dough so cut, all substantially as set forth.

809,444. TURPENTINE-BOX-CUTTING MACHINE. ROSWELL L. IVEY and RONALD D. MCDONALD, De Land, Fla., assignors of one-third to Sidney V. Hough, De Land, Fla. Filed Apr. 4, 1905. Serial No. 253,847.

Claim.—1. In a machine substantially as described, the combination of the cross-head having the body portion provided with side rails or ribs, and the transversely-movable tool-carrier having bearings for the cutter-shaft, the cutter-shaft in said bearings having a shoulder limiting the outward movement of the shaft, whereby the shaft may be fed inwardly by a feed-screw, the feed-screw for feeding the tool-carrier transversely, the main frame having the opposite uprights composed of front and rear bars spaced apart to form guideways for the rails of the cross-head, said cross-head being provided with upright bearings for its adjusting-screws, the adjusting-screws journaled to the main frame and threaded in the bearings of the cross-head, the cross-shaft geared with the screws for adjusting the cross-head, the upper and lower tension-screws for pressing the main frame away from a tree, chains to pass around the tree and the screws connected with the main frame for tightening said chains to hold the main frame to the tree, the dogs adapted at one end to engage with the tree, and the screws connecting the other ends of the dogs with the main frame for securing the main frame to the tree, all substantially as and for the purposes set forth.

2. In a machine substantially as described, the combination with the main frame, the cutter for forming a box in a tree, and the means for supporting and adjusting the cutter, of means for binding the main frame in connection with the tree, and means for pressing the main frame away from the tree in opposition to the binding means, substantially as set forth.

3. In a machine substantially as described, the combination of the uprights spaced apart forming a way for the cross-head, and consisting of front and rear bars spaced apart forming guides for the rails or ribs on the cross-head, the top plate connecting the cross-bars and having bearings for the cross-shaft and for the screw-shafts, the cross-shaft and the screw-shafts being geared together, the upper cross-bar extending between the uprights and projecting beyond the same and having bearings for the upper chain-securing screws, the arch or cross bar extending between the upper ends of the uprights and having a bearing for the upper tension-screw for pressing the frame away from a tree, and adjusting the machine to any desired angle with the tree, a chain for connection with the chain-screws and adapted to pass around a tree, the cross-head having bearings for its feed-screws and comprising the main or body portion, and the cutter-carrier movable transversely therein, means for moving the cutter-carrier transversely of the body portion of the cross-head, the cutter and its shaft, means for bracing the lower end of the main frame away from a tree, the lateral lugs on the front bars of the uprights and having the rearwardly-inclined wings provided with bearings for dog-securing screws, the dog-securing screws and the dogs connected at one end with the screw and adapted at their other ends to engage with a tree-trunk, substantially as and for the purposes set forth.

4. The combination in a machine substantially as described, of the main frame, uprights having front and rear bars spaced apart, the front bars being provided with lateral lugs having projecting wings forming bearings for dog-securing screws, the said screws and the dogs secured thereto, the lower cross-bar connecting the uprights and extending laterally beyond the same, the plates J secured at their upper ends to the laterally-projecting lugs of the uprights and lapping at their lower ends along the extended ends of the lower cross-bar and secured thereto, and screws threaded in said plates and adapted to brace the lower end of the main frame away from a tree-trunk, a chain to pass around the tree-trunk and screws threaded in said plates for tightening such chain, substantially as and for the purposes set forth.

5. A machine for cutting boxes in turpentine-trees, comprising a main frame, means for securing and bracing the main frame in connection with a tree, a cutter-head adapted to cut the box in the tree, and means supported by the main frame for carrying and adjusting the said cutter, substantially as set forth.

6. The combination in a machine for cutting boxes in turpentine-trees, of a main frame having the opposite uprights connected together, lateral extensions beyond the uprights, screw devices carried by the said lateral extensions for securing and bracing the main frame in connection with a tree-trunk, a cross-head movable between the uprights and having a transversely-movable cutter-carrier, means for adjusting the cross-head longitudinally between the uprights, means for adjusting the cutter-carrier transversely, and the cutter and its shaft supported by said carrier, substantially as set forth.

7. A machine for cutting boxes in turpentine-trees, comprising a cutter and its shaft, a main frame, a cross-head operating in said main frame and having bearings for the cutter-shaft, and devices carried by the main frame for securing and bracing the same in connection with a tree-trunk, substantially as set forth.

8. A machine for use in cutting turpentine-boxes comprising a main frame, a cross-head movable in said frame and having a transversely-movable cutter-carrier, means for holding the main frame to and bracing it from a tree, the cutter-shaft journaled in the carrier portion of the cross-head and a cutter-head on the said shaft having at its inner and outer sides cutting-plates whose outer edges are projected in the direction of revolution of the cutter and are curved from the center of the cutter outwardly toward its periphery to form the curved inner and outer walls of a box in a tree-trunk, substantially as set forth.

9. In a machine substantially as described, a cutter-head having on its inner and outer sides cutter-blades curving from the center of the head outwardly, the cutting edges of the blades projecting in the direction of revolution of the head, substantially as and for the purposes set forth.

10. A cutter-head, comprising the body or stock, the edge or lead cutters secured to said stock and the side cutters on opposite sides of the stock having their cutting edges curved from end to end, substantially as described.

11. A cutter-head for cutting turpentine-boxes in tree-trunks comprising a body or stock and blades at the inner and outer sides thereof, the blades at the outer side of the stock being given a bulge or swell whereby to cut the mouth of the turpentine-box approximately level, substantially as described.

12. The combination in a cutter-head of the body-plate, the ribs projecting on the opposite sides thereof and the side cutters having the face-plates lapped against and secured to said ribs and their outer cutting edges curved, substantially as described.

13. In a cutter-head the combination with the body or stock plate having on its opposite sides the projecting ribs and provided with the openings alongside said ribs, of the side cutters secured to the ribs on opposite sides of the stock or body plate, one set of said cutters being provided with lugs projecting into the openings in said body-plate and means securing the cutters to the oppositely-projecting ribs, substantially as set forth.

14. The combination in a cutter-head with the body-plate and the ribs projecting therefrom, of the side cutters having their face-plates lapped alongside of and secured to said ribs, said side cutters being curved on their outer edges and overlapping at their outer ends the outer edge of the body-plate, substantially as set forth.

15. The combination in a cutter-head with a body or stock plate provided on its opposite sides with the projecting ribs and having in its outer edge notches alongside the said ribs of the side cutters having their face-plates lapping alongside of and secured to the said ribs and provided at their outer ends with projecting portions fitting in the edge notches of the stock-plate and lapping the outer edge of the said plate, substantially as set forth.

16. A cutter-head for use in cutting turpentine-boxes in tree-trunks having cutters at its inner and outer sides and presenting in cross-section a form tapering toward its periphery whereby said cutter when revolved in contact with and at an inclined angle to a tree-trunk, will cut a pocket constituting the so-called box in said trunk, substantially as set forth.

17. A cutter-head for cutting turpentine-boxes in tree-trunks comprising a body or stock, edge or lead cutters at the periphery of said cutter-head and inner and outer side cutters having their outer or cutting edges curving gradually toward each other at the periphery of the cutter-head, the lead-cutters being arranged between the adjacent pairs of side cutters, substantially as and for the purposes set forth.

18. A revolving tool for cutting turpentine-boxes in tree-trunks comprising the body or stock, the lead blades or cutters arranged midway between its inner and outer faces and the inner and outer curved blades at the opposite faces of the cutter with their cutting edges extending approximately in the line of direction of revolution of the cutter-head and with the outer blades given a swell or bilge whereby to form the mouth of the pocket or box on approximately a straight line at its lower edge, substantially as set forth.

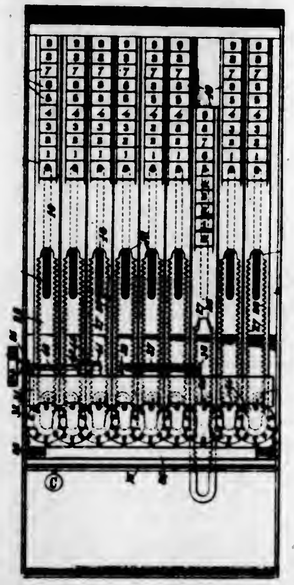
809,445. SAMPLE-DISPLAY-CASE. ALFRED JELLIFFE, St. Louis, Mo. Filed May 5, 1905. Serial No. 259,866.

Claim.—1. In a device of the class described, the combination with a casing having a transparent panel, said casing having slots in the side walls thereof, rollers journaled in the sides of the casing, and resiliently-supported bearings for the rollers, which bearings have a tendency to force the rollers against the panel; substantially as described.

2. In a device of the class described, the combination with a casing, of a transparent panel carried by the casing, a partition carried by the casing and parallel with the panel, rollers at the respective ends of the partition, and resiliently-supported bearings for the rollers, which bearings have a tendency to maintain the peripheries of the rollers in contact with the panel; substantially as described.

3. In a device of the class described, the combination with a casing having a transparent panel, of oppositely-rotatable rollers carried by the casing, a web wound on said rollers and having different kinds of material stitched thereto, and resiliently-supported bearings for the rollers exerting pressure thereagainst to force the material against one surface of the panel irrespective of the diameter of the roll of material on either of the rollers; substantially as described.

809,446. CALCULATOR. FREDERICK G. JOHNSON, Hartford, Conn. Filed June 20, 1903. Serial No. 162,370.



Claim.—1. In a calculator the combination with a case provided with a septum, reciprocatory actuating-bars and their alining members on one side of the septum, and actuating bar-springs upon the other side of the septum, of means for imparting measured movement to the respective bars, and means for registering the degree of movement so imparted.

2. In a calculator the combination with a case provided with a septum, reciprocatory actuating-bars and their alining members on one side of the septum, and actuating bar-springs upon the other side of the septum, of means for imparting measured movement to the respective bars, and means for registering collectively the degree of movement so imparted.

3. In a calculator the combination with a case, spring-retracted actuating-bars provided respectively with a pair of racks, registering mechanism including pinions adapted to mesh with said racks, and means for shifting the pinions from engagement with one set of racks to the other.

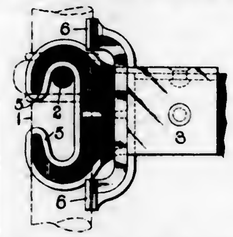
4. In a calculator the combination with a case, spring-retracted actuating-bars provided respectively with a pair of racks, registering mechanism including pinions adapted to mesh with said racks, and means for shifting the pinions from engagement with one set of racks to the other, said means for shifting the pinions consisting of a pair of relatively adjustable pinion-bearing boxes.

5. In a calculator the combination with a case, spring-retracted actuating-bars provided respectively with a pair of racks, registering mechanism including pinions adapted to mesh with said racks, means for shifting the pinions from engagement with one set of racks to the other, said means for shifting the pinions consisting of a pair of relatively adjustable pinion-bearing boxes, and means for fixing the adjustment of the said boxes.

6. In a calculator the combination with a case, a plurality of spring-retracted actuating-bars, and registering mechanism including a corresponding plurality of staffs and dial-plates, of mechanism operatively connecting the respective bars and staffs, including clutch mechanism, whereby the positive movements only of the bars are registered, and mechanism for disengaging the clutch mechanism.

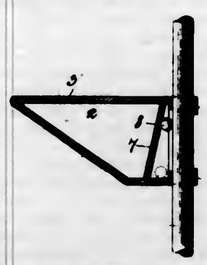
7. In a calculator the combination with a case, spring-retracted actuating-bars, and registering mechanism comprising respectively staffs and dial-plates, of pinions operatively connecting the staffs and their respective bars, means for reversing the operative relations between said pinions to their bars, and means for simultaneously reversing the operative relations of said pinions to their dial-plates.

809,447. CORNER-FASTENING FOR BEDS. BENJAMIN H. JONES, St. Louis, Mo. Filed Apr. 14, 1905. Serial No. 255,545.



Claim.—In a corner-fastening for beds, the combination with a metal bed post and its connecting tie-rod, of a casting, a rail secured to said casting, a laterally-extending hook on said casting for engaging the tie-rod, and bearing-points on the casting located above and below the hook and in line with the post for engaging said post; substantially as described.

809,448. ADJUSTABLE BRACKET. SOLOMON KAHN, Cadillac, Mich. Filed Nov. 1, 1904. Serial No. 231,016.

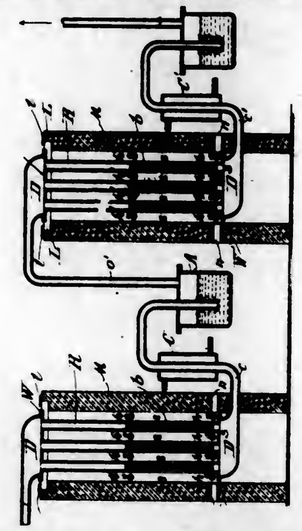


Claim.—The combination with a standard, of a bracket having a sleeve adapted to receive the standard, the inner wall of the sleeve being slotted, said bracket having an inclined wall, and a ball located in the bracket between the inclined and slotted walls, said ball being adapted to be thrown into contact with the inclined wall and to project slightly through the slotted wall into engagement with the standard, substantially as described and for the purpose set forth.

809,449. HARNESS-PAD. WILLIAM L. KELLERMAN, Oskaloosa, Iowa, assignor of one-half to Scott H. Hull, Oskaloosa, Iowa. Filed Mar. 10, 1906. Serial No. 305,410.

Claim.—A harness-pad comprising a body or back, fillings disposed below said body or back, at opposite sides of the transverse center of the same, a bottom layer in which the fillings and the body or back are arranged; said bottom layer being one piece of material and having longitudinal bights receiving the edges of the body or back throughout the length of said edges and end bights receiving the opposite ends of the body or back throughout the length of said ends, and means extending through and connecting the opposite portions of the longitudinal and end bights together and to the body or back at intervals throughout the length of the pad.

809,450. PROCESS OF MAKING SULFURIC ANHYDRID. RUDOLF KNIETSCH, Ludwigshafen-on-the-Rhine, Germany, assignor, by mesne assignments, to General Chemical Company, a Corporation of New York. Filed Sept. 24, 1901. Serial No. 76,333.



Claim.—1. The process of manufacturing sulfuric anhydrid which consists in passing sulfurous-acid gas and oxygen over contact substance containing platinum, interrupting the process when the conversion has been partially effected, removing sulfuric anhydrid formed and subjecting the unconverted gases thus freed from sulfuric anhydrid to further action of contact substance containing platinum.

2. The process of manufacturing sulfuric anhydrid which consists in passing sulfurous-acid gas and oxygen over contact substance containing platinum which is subjected to a regulated cooling so as to remove the excess of heat due to the reaction, interrupting the process when the conversion has been effected to an extent of about seventy to ninety per cent., removing sulfuric anhydrid formed and subjecting the unconverted gases thus freed from sulfuric anhydrid to further action of contact substance containing platinum.

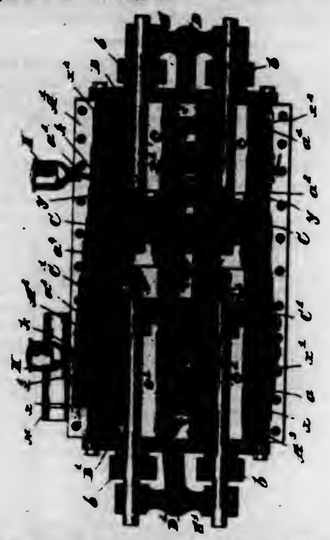
3. The process of manufacturing sulfuric anhydrid which consists in passing sulfurous-acid gas and oxygen over contact substance containing platinum, interrupting the process when the conversion has been partially effected, removing sulfuric anhydrid formed and passing the unconverted gas thus freed from sulfuric anhydrid over contact substance containing platinum, interrupting the process when a portion of the remaining sulfur dioxid has been converted into sulfuric anhydrid, removing sulfuric anhydrid formed and subjecting the remaining unconverted gases to further action of contact substance containing platinum.

809,451. DOUBLE-ACTING EXPLOSIVE-ENGINE. JOSEPH W. KYLE and JOHN W. HICKS, Chicago, Ill., assignors of one-third to Garfield G. Bennett, Chicago, Ill. Filed Dec. 17, 1903. Serial No. 185,868.

Claim.—1. An explosive-engine comprising a cylinder, simultaneously reciprocating pistons in each end thereof, a generating and mixing device, a pipe leading therefrom and opening into each end of the cylinder beyond the outermost travel of the pistons, an inlet-port in open communication with the pipe and disposed between the pistons when at their outermost limit of movement, an exhaust-port also opening between the pistons when so positioned, a sparker po-

16. The combination with a plurality of cylinders, of a simulta-

sitioned to ignite the charge when the pistons are at their inward limit of movement, a transverse shaft intermediate the ends of the cylinder, a plurality of oppositely-disposed cranks thereon and means connecting the outer ends of said pistons with said cranks and adapted to rotate said shaft.



2. The combination with a cylinder, of simultaneously and oppositely reciprocating pistons in each end thereof, unvalved communicating ports opening into each end of the cylinder beyond the outermost travel of the pistons, a like port opening between the pistons when in said position, means for supplying an explosive mixture through said ports into the ends of the cylinder which serve as compression-chambers and from thence between the pistons which in their inward movement compress the charge, a sparker disposed centrally of the cylinders and acting to ignite the mixture when under maximum compression, a transverse shaft, oppositely-disposed cranks thereon and a plurality of connecting-rods connecting said pistons with said cranks.

3. An explosive-engine comprising a two-part casing rigidly bolted together and cored to provide inlet-passages, an exhaust-passage and a water-chamber, a cylindric bushing secured therein forming the engine-cylinder, oppositely and simultaneously reciprocating pistons in said cylinder having outwardly-extending piston-rods, a shaft disposed transversely of the pistons, a crank-arm on each end thereof, a cross-head on each of the piston-rods, and a connecting-rod secured on each end of each cross-head and operatively connected with the crank on each side of the engine.

4. An engine comprising a cylinder having a cast-metal jacket or casing surrounding the same and cored to provide an inlet-passage at each end of the same, an exhaust-passage intermediate of the ends, communicating water-passages surrounding the cylinder, oppositely and simultaneously reciprocating pistons in each end of the cylinder which act to compress the explosive mixture at the outward movement and compress the charge on the inward movement, and a centrally-disposed sparker acting to ignite the charge at maximum pressure, a transverse shaft having a double crank on each side of the cylinder and a cross-head at each end of the cylinders and reciprocated by the pistons and connecting-rods on each side of the cylinders engaged on each end of each cross-head and connecting the same with the cranks.

5. The combination with two parallel cylinders, of a transverse shaft extending centrally between the same, a double crank on said shaft on each side of the cylinder, a reciprocating piston in each end of each cylinder the piston-rods of which extend through the cylinder-heads and are rigidly connected at each end by a cross-head, a connecting-rod journaled on each side of each cross-head and connected with the cranks on said shaft on each side of the cylinder, ports arranged to admit the explosive mixture into the ends of the cylinders for initial compression and between the pistons for final compression and a sparker in each cylinder extending between the pistons.

6. In a double-acting engine the combination with parallel cylinders of oppositely and simultaneously reciprocating pistons in each end of each, a cross-head rigidly connected with the piston-rods at each end of the cylinders, a shaft extending centrally and transversely between the cylinders and provided on each side of the engine with a double crank, one of which is set obliquely with respect to the shaft and connecting-rods journaled on each side of each cross-head connected at their inner ends on said cranks.

7. In an engine the combination with pistons reciprocating oppositely in pairs, of a cross-head at each end of the engine, each rigidly connected with a plurality of the pistons, a connecting-rod on each side of each cross-head, a shaft having a plurality of double cranks thereon with which the connecting-rods engage and means for reciprocating the pistons.

8. In an engine the combination with pistons reciprocating oppositely in pairs, of a cross-head at each end of the engine, each rigidly connected with a plurality of the pistons, a connecting-rod on each side of each cross-head, a shaft having a plurality of double cranks thereon with which the connecting-rods engage and means for injecting and compressing an explosive mixture between the pistons and means for exploding same.

9. In a device of the class described the combination with oppositely-reciprocating pistons, the cross-heads, shafts and connecting-rods, of a generating and mixing device positioned near one end of the cylinder, a pump operated from one of the cross-heads and acting to force fluid hydrocarbon into the generating and mixing chamber and means for regulating the action of the pump.

10. In a device of the class described the combination with oppositely-reciprocating pistons, the cross-heads, shafts and connecting-rods, of a generating and mixing device positioned near one end of the cylinder, a pump operated from one of the cross-heads and acting to force fluid hydrocarbon into the generating and mixing chamber and means for regulating the action of the pump.

11. The combination with an engine-cylinder having oppositely-reciprocating pistons therein, of a generating-chamber, a pump positioned and connected to force hydrocarbon fluid into the generator at each stroke of the piston in regulable amounts, a tappet-arm carried on one of the cross-heads and adapted to actuate the pump, a valved pipe leading from the generating-chamber longitudinally of the cylinders and unvalved ports opening therefrom into the cylinders at each end thereof whereby the inward movement of the pistons acts to draw the explosive fluid into the ends of the cylinders.

12. The combination with an engine-cylinder having oppositely-reciprocating pistons therein, of a generating-chamber, a pump positioned and connected to force hydrocarbon fluid into the generator at each stroke of the piston in regulable amounts, a tappet-arm carried on one of the cross-heads and adapted to actuate the pump, a valved pipe leading from the generating-chamber longitudinally of the cylinders and unvalved ports opening therefrom into the cylinders at each end thereof whereby the inward movement of the pistons acts to draw the explosive fluid into the ends of the cylinders, and a port opening between the pistons and acting to admit the fluid therefrom between the pistons.

13. In an explosive-engine the combination with two cylinders located one above the other, of a simultaneously and oppositely reciprocating piston in each end of each cylinder, cross-heads connecting the outwardly-extending ends of the piston-rods thereof, laterally-directed arms on each cross-head, a shaft extending centrally and transversely between the cylinders, a double crank on each end thereof, a connecting-rod journaled on each of the projecting arms of each cross-head and each connected at their inner ends with the respective cranks on said shaft.

14. In an explosive-engine the combination with two cylinders located one above the other, of a simultaneously and oppositely reciprocating piston in each end of each cylinder, cross-heads connecting the outwardly-extending ends of the piston-rods thereof, laterally-directed arms on each cross-head, a shaft extending centrally and transversely between the cylinders, a double crank on each end thereof, a connecting-rod journaled on each of the projecting arms of each cross-head and each connected at their inner ends with the respective cranks on said shaft, means for admitting explosive mixture between the pistons in each cylinder and compressing the same by the inward movement of said pistons and a sparker disposed between the pistons and each cylinder and acting to release the fluid when at maximum compression.

15. The combination in an explosive-engine, of a plurality of parallel cylinders located one above the other, a shaft extending transversely between the cylinders, a double crank on each end thereof, said double cranks being arranged with their centers out of alinement with the center of the shaft.

16. The combination with a plurality of cylinders, of a simultaneously and oppositely reciprocating piston in each end of each cylinder, a cross-head connecting the ends of the piston-rods at each end of the cylinders, laterally-projecting arms on each cross-head extending beyond the sides of the cylinders, a shaft extending transversely between the cylinders a double crank on each end, connecting-rods journaled at their outer ends on the ends of said arms and at their inner ends on the respective cranks on said shaft, a generating and mixing device for hydrocarbon fluid operated from one of the cross-heads and unvalved passages and ports adapted to admit the explosive mixture into the ends of the cylinder during the inward movement of the pistons, to be compressed during the outward movement thereof and a passage connecting with the ends of the cylinders adapted to admit the same between the pistons under maximum pressure whereby inward movement of the pistons acts to complete the compression and means for igniting the charge when under maximum compression.

17. The combination with a plurality of cylinders, of a simultaneously and oppositely reciprocating piston in each end of each cylinder, a cross-head connecting the ends of the piston-rods at each end of the cylinders, laterally-projecting arms on each cross-head extending beyond the sides of the cylinders, a shaft extending transversely between the cylinders a double crank on each end, connecting-rods journaled at their outer ends on the ends of said arms and at their inner ends on the respective cranks on said shaft, a generating and mixing device for hydrocarbon fluid operated from one of the cross-heads and unvalved passages and ports adapted to admit the explosive mixture into the ends of the cylinder during the inward movement of the pistons, to be compressed during the outward movement thereof and a passage connecting with the ends of the cylinders adapted to admit the same between the pistons under maximum pressure whereby inward movement of the pistons acts to complete the compression, and electrically-operated sparkers disposed between the pistons of each cylinder and acting to ignite the charge.

18. In an explosive-engine the combination with a plurality of cylinders having in their ends oppositely-reciprocating pistons, a generating and mixing device connected with said cylinders and adapted to supply an explosive mixture into the ends of the cylinders during the inward stroke of the piston, a passage and ports permitting the escape of said mixture into the cylinders between the pistons when compressed by the outward stroke thereof, an electrically-operated sparker intermediate of said pistons comprising an insulated tappet-arm having at its inner end a conducting contact-piece adapted to make and break contact with one of the pistons, an electrical connection at the outer end of said sparker and a driving-shaft extending transversely between said cylinders.

19. The combination with a cylinder of oppositely-reciprocating pistons in the ends thereof, means for admitting an explosive mixture into the ends of the cylinder during the inward stroke of the piston, a relief-cylinder connected by ports with said ends of the cylinders and adapted to permit the compression of the explosive mixture therein during the outward stroke of the pistons, an exhaust-port located between the pistons when at the outermost limit of their travel and ports leading from the relief-cylinder to a point intermediate of the piston and adapted to deliver the explosive mixture between the cylinders for final compression and combustion.

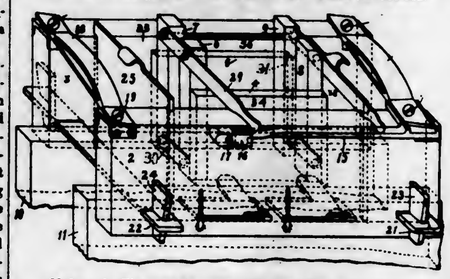
20. In an explosive-engine a relief-cylinder communicating with the compression ends of the explosion-cylinder, a passage and port leading therefrom and opening into the combustion-chamber when the fluid is under maximum compression, and a spring-pressed piston in said relief-cylinder acting to maintain uniform tension on the said explosive fluid when said passage and ports are open.

21. The combination in an explosive-engine comprising a cylinder having oppositely-movable pistons in the end thereof, a generating and mixing device connected to supply an explosive mixture into the ends of the cylinder during the inward movement of the piston, a relief-cylinder connected with the ends of the cylinder and a compression-cylinder connected with the ends of the combustion-cylinder, a spring-pressed piston-head therein acting to maintain approximately uniform tension on the fluid, a passage and ports leading therefrom and connecting with the combustion-chamber between the pistons when the same are at the outward limit of their stroke, an exhaust-passage also located between the pistons when so positioned and means whereby the charge is ignited at the maximum compression during the inward stroke of the piston.

22. In an explosive-engine the combination with a plurality of cylinders of a crank-shaft extending transversely between the same, a plurality of cranks on said shaft arranged in obliquely-disposed pairs, a piston in each end of each cylinder, rods connecting said pistons with said cranks a hydrocarbon-generator operated by the movement of the pistons and means for admitting hydrocarbon from the generator to said cylinders.

23. In an explosive-engine the combination with a plurality of cylinders of a shell inclosing the same, a piston in each end of the cylinders, inlet-ports between the cylinder and shell at each end of the cylinder, an inlet and an exhaust port opening between the pistons when at their outer limit of movement, transverse crank-shaft intermediate the cylinders, cranks thereon and means connecting said cranks with the outer ends of the piston-rods.

809,452. **MACHINE FOR MOLDING HOLLOW WALLS.** ISRAEL L. LANDES, Chicago, Ill. Filed Apr. 1, 1905. Serial No. 253,358.



Claim.—1. The combination with a molding-machine comprising a pair of mold-boards and means for moving said mold-boards longitudinally and laterally relatively to each other, of a core having sides movable vertically relatively to each other, connecting-links for the lower parts of said sides and levers pivoted to the upper parts of said sides for yoking said upper parts together and for moving said sides relatively in a vertical plane.

2. A molding-machine comprising mold-boards movable laterally and longitudinally relatively to each other and a core having sides connected by pivoted cross-bars or links, a lever overlying the tops of said mold-boards and pivoted thereto, said lever arranged to move said mold-boards in a horizontal plane, a similar lever, or several thereof, pivoted to the sides of said core and adapted to move one of said sides vertically and laterally relatively to the other side, and a connecting cross-bar pivoted to said mold-boards to assist in supporting the latter in their relative positions and to move with said lever.

3. In a molding-machine, the combination of a pair of mold-boards, with means for moving said mold-boards longitudinally and laterally relatively to each other, a core having sides arranged to be moved relatively to each other, means for supporting said sides in their relative positions, and gates, or partition-walls, which are adjustable between said mold-boards to make an inclosed mold-space around said core.

4. In a molding-machine, in combination, a pair of mold-boards movable toward and from each other in parallel planes, means for moving said mold-boards, means for yoking said mold-boards together temporarily against relative movement during formation of a cast, means for partitioning off a portion of the mold-space between said mold-boards, a core having sides arranged to move toward and from each other in parallel planes, said core being free of said mold-boards and adjustable in any suitable position within said portion of said mold-space.

5. In a molding-machine, the combination with a pair of mold-boards movable longitudinally and laterally relatively to each other in a horizontal plane, of core sides movable relatively to each other in a vertical plane, means for moving said mold-boards, means for yoking said mold-boards together against relative movement, means for moving said core sides, means for supporting said mold-boards upon a hollow wall, and removable end gates or partition-walls which divide the space between said mold-boards into a mold-space adapted to receive said core sides.

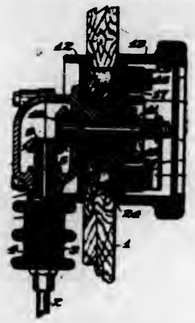
809,453. **HIGH-TENSION-CURRENT DISTRIBUTER FOR INTERNAL-COMBUSTION ENGINES.** LEON J. LE POUTRE, New Rochelle, N. Y., assignor to Poly-Phase Ignition System Company, a Corporation of New York. Filed Dec. 13, 1904. Serial No. 236,604.

Claim.—A high-tension-current distributer comprising a cylindrical casing of an insulating material, a plurality of projections

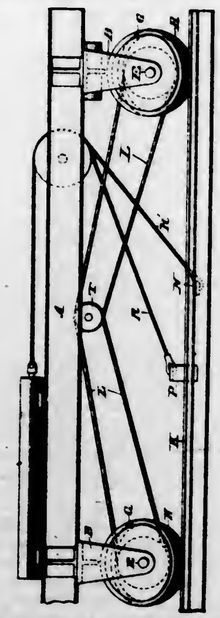
extending from the base of said casing, metallic segments secured to

two sets of traction-wheels on the machine, the wheels of each set

extending from the base of said casing, metallic segments secured to said projections, each of said segments being connected to a terminal leading to a corresponding spark-plug, a shaft supported in a bearing carried by said casing, a current-distributing arm secured to the outer end of said shaft and adapted to pass in close proximity to said segments, means to rotate said shaft and arm so as to cause the latter to distribute to said segments successively sufficient current for the efficient ignition of an explosive mixture, and a circular wall also projecting from the base of the casing and interposed between said bearing and said segments for the purpose described.



809,454. TRAVERSING MECHANISM. WILLIAM B. MAGER, South Milwaukee, Wis., assignor to The Bucyrus Company, South Milwaukee, Wis., a Corporation of Wisconsin. Filed Apr. 24, 1905. Serial No. 257,178.



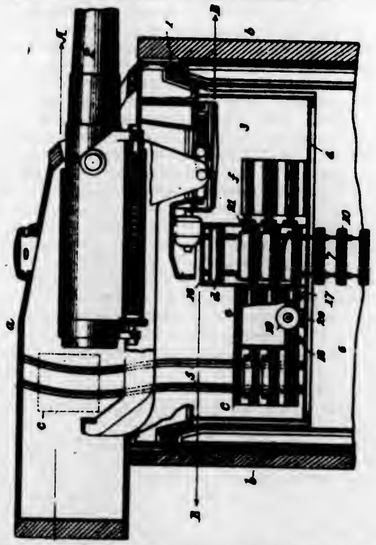
Claim.—1. Apparatus for traversing or transporting excavators or other heavy machinery, comprising two movable parallel track-sections, inner and outer sets of traction-wheels on the machine coöperating with the respective track-sections, the wheels of each set having flattened portions, the flat portions of the respective sets lying adjacent the normal portions of the other set, whereby the machine is alternately supported by the respective sets of wheels, and means for advancing the respective track-sections as they are disengaged from the coöperating set of wheels.

2. Apparatus for traversing or transporting excavators or other heavy machinery, comprising two movable parallel track-sections, two sets of traction-wheels on the machine, the wheels of each set having flattened, peripheral portions lying adjacent circular portions of the other set, means for driving the traction-wheels, and means for advancing the respective track-sections as they are alternately freed from the coöperating traction-wheels.

3. Apparatus for traversing or transporting excavators or other heavy machinery, comprising two movable parallel track-sections, two sets of traction-wheels on the machine, the wheels of each set having flattened, peripheral portions lying adjacent circular portions of the other set, means for driving the traction-wheels, and power mechanism on the machine connected to the respective track-sections for advancing the latter as they are alternately freed from the coöperating traction-wheels.

4. Apparatus for traversing or transporting excavators or other heavy machinery, comprising two movable parallel track-sections, two sets of traction-wheels on the machine, the wheels of each set having flattened, peripheral portions lying adjacent circular portions of the other set, means for driving the traction-wheels, and power mechanism on the machine having cables connected to the respective track-sections for advancing the latter as they are alternately freed from the coöperating traction-wheels.

809,455. AMMUNITION-HOISTING MECHANISM. JOHN F. MINES and ROBERT P. STOUT, South Bethlehem, Pa., assignors to Bethlehem Steel Company, South Bethlehem, Pa., a Corporation of Pennsylvania. Filed Sept. 14, 1904. Serial No. 224,440.



Claim.—1. In ammunition-elevating mechanism, the combination with a gun, of two elevators and an intermediate transfer-car adapted to transfer ammunition from the handling-room to the gun.

2. In ammunition-elevating mechanism, the combination with a gun, of an elevating-car adapted to deliver ammunition at the breech of the gun, a second elevator adapted to deliver ammunition at the lower station of the elevating-car, and a transfer-car located between said elevators at said lower station.

3. In ammunition-elevating mechanism, the combination with a gun, of an elevator adapted to deliver ammunition at the breech of the gun, a second elevator adapted to raise ammunition from the handling-room, said elevators being out of register with each other, and a transfer-car movable to register with said elevators alternately.

4. In ammunition-elevating mechanism, the combination with a gun, of an elevator adapted to raise ammunition from the handling-room, a second elevator adapted to deliver the ammunition at the breech of the gun, a transfer-car between said elevators, a rammer adapted to move the ammunition from the first elevator to the transfer-car, and a second rammer adapted to move the ammunition from the transfer-car to the second elevator.

5. In ammunition-elevating mechanism, the combination with a gun, of a chain elevator adapted to raise the ammunition from the handling-room, an elevating-car adapted to deliver the ammunition at the breech of the gun, a transfer-car between said elevators, a series of rammers adapted to transfer the ammunition from the chain elevator to the transfer-car, and a second series of rammers adapted to transfer the ammunition from the transfer-car to the elevating-car.

6. The combination with a turret and a gun mounted therein, said turret having a floor extending over the handling-room, of an elevator extending through an opening in said floor from the handling-room into the turret, a cover extending over said opening and elevator, a second elevator within the turret, and a transfer-car between said elevators.

7. The combination with a turret and a gun mounted therein, said turret having a floor extending over the handling-room, of a chain elevator supported on said floor and provided with flights adapted to hold ammunition, a transfer-car movable on said floor, and a plurality of rammers adapted to move a number of sections of ammunition simultaneously from said chain elevator to said car.

8. In an ammunition-elevating mechanism, the combination with a gun, of an elevator adapted to raise the ammunition from the handling-room, a second elevator adapted to deliver the ammunition at the breech of the gun, and means, including a rammer, for transferring the ammunition from the first-mentioned elevator to the second elevator.

9. The combination with a turret and a gun mounted therein, said turret having a floor extending over the handling-room, of a chain elevator supported on said floor and extending through an opening in the floor to the handling-room, and a casing or cover over said elevator and opening, said elevator being provided with pivoted flights, and means for folding said flights upon the chains within said casing whereby a casing of minimum size may be used.

10. In ammunition-hoisting mechanism, the combination with a chain elevator, a transfer-car, and an elevating-car, of a multiple rammer adapted to move several sections of ammunition simultaneously from the chain elevator to the transfer-car, and a second multiple rammer located between the branches of the chain elevator and adapted to move several sections of ammunition from the transfer-car to the elevating-car.

11. The combination with a turret, and a gun mounted therein, said turret having a floor extending over the handling-room, of an elevating apparatus supported on and extending through an opening in said floor, and a normally closed casing extending over said elevator, whereby sparks are prevented from passing below the turret-floor said casing having openings for the passage of ammunition and means for normally closing the same.

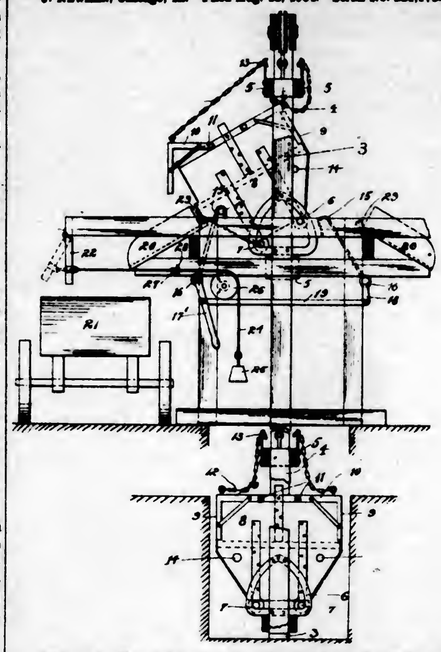
12. The combination with a turret, and a gun mounted therein, said turret having a floor extending over the handling-room, of an elevating apparatus supported on and extending through an opening in said floor, a normally closed casing extending over said elevator, said casing having openings through which the ammunition is discharged into the turret, and shutters for normally closing said openings.

13. In ammunition-elevating mechanism, the combination with a gun, of an elevator adapted to raise the ammunition from the handling-room, a second elevator adapted to deliver ammunition at the breech of the gun, and a transfer-car between the upper station of the first-named elevator and the lower station of the second elevator, the said stations being laterally displaced and the car being movable to register with each of said stations.

14. In ammunition-elevating mechanism, the combination with a turret and a gun mounted therein, of an elevator adapted to raise ammunition from the handling-room into the turret, a second elevator within the turret adapted to deliver ammunition at the breech of the gun, the upper station of the former elevator and the lower station of the latter being out of register, and an intermediate transfer-car movable to register with each of said stations and adapted to hold a charge of ammunition.

15. In ammunition-elevating mechanism, the combination with a turret and a gun mounted therein, of an elevator adapted to raise ammunition from the handling-room to the turret, a second elevator adapted to deliver the ammunition at the breech of the gun, each of said elevators being adapted to simultaneously hold a plurality of sections of ammunition and the upper station of the first-named elevator and the lower station of the second elevator being at the same elevation, but out of register with each other, a horizontally-movable transfer-car arranged between said stations and adapted to register with each of them, and rammers adapted to transfer the ammunition from the first elevator to the transfer-car and from the said transfer-car to the second elevator.

809,456. AUTOMATIC-DUMPING ELEVATOR-CAGE. WILLIAM J. NEWMAN, Chicago, Ill. Filed Aug. 18, 1904. Serial No. 221,176.



Claim.—1. The combination of an elevator-frame, heart-shaped supports secured to said frame, a dumping-hopper or box mounted on shafts having their ends carried in said supports, the arrangement being such that said hopper will normally rest in upright position, but may be swung to dump at either side.

2. In an automatic-dumping elevator, the combination of a slidable cage-frame, substantially heart-shaped bearings in said frame, a hopper resting on two shafts having their ends in engagement with said bearings, and adapted to be supported thereby, the bottom of said hopper being at some distance above said shafts, springing doors for said hopper, catches on said hopper, and means for engaging said catches when the elevator is being raised in order to automatically dump the same.

3. The combination with an elevator-cage or the like, of a dumping-platform, two pairs of trunnions or the like for supporting said platform, bearings in said cage for said trunnions, the arrangement being such that the platform may be tipped in either direction, said bearings forming guides for one pair of said trunnions when the other pair are acting as pivots.

4. The combination with an automatic-dumping elevator adapted to dump on either side and provided with dumping-rods, of pairs of hooks mounted on either side of the main frame, and means whereby either of said pairs of hooks may be thrown into position for engaging its corresponding rod, the opposite pair of hooks being simultaneously thrown out of position for engagement.

5. The combination of oppositely-disposed dumping-hooks for an elevator, shafts on which said hooks are mounted, a lever on one of said shafts, and means connecting between said lever and the other shaft whereby a movement of the lever will cause the corresponding movement of both shafts.

6. In a dumping-elevator, the combination of a slidable cage, bearings in said cage, a dumping-platform supported at some distance above said bearings, a pair of shafts having their ends resting in said bearings for supporting said platform, the arrangement being such that the platform may be tipped in either direction, one of said shafts acting as a pivot while the other shaft is guided in said bearings to control the dumping action.

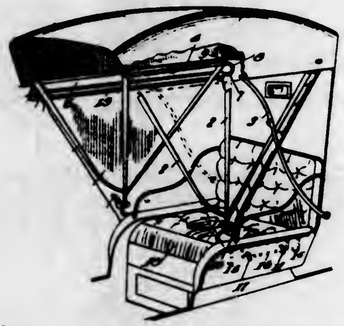
7. In a dumping-elevator, the combination of a slidable cage, bearings in said cage, a pair of shafts having their ends resting in said bearings, a dumping-hopper mounted on said shafts and adapted to swing in either direction upon one of said shafts, one shaft act-

ing as a pivot and the other as a guide, swinging doors for said hopper and means connecting between said doors and said cage whereby one of the doors will be opened when the hopper is swung toward its corresponding side, and means for dumping said hopper.

8. In an apparatus of the character set forth, the combination with a discharge-chute for heavy materials adapted to discharge into wagons, of a swinging spill-board, and means for holding said spill-board in normal position in front of the chute, whereby the material will strike said board to prevent undue striking against the wagons.

9. In an apparatus of the character set forth, the combination with a discharge-chute adapted to discharge into wagons or the like, of a pivoted spill-board and a weight for yieldingly holding said spill-board in normal position to receive the force of material discharged through said chute.

809,457. CURTAIN-HOLDER FOR BUGGY-TOPS. CYRUS W. NOBLE and EARL O. MCHENRY, Hoytville, Ohio. Filed June 10, 1905. Serial No. 264,713.



Claim.—1. In combination, a carriage-top embodying a plurality of bows, curtain-holders arranged at opposite sides of the top, each curtain-holder having permanent connection at one end with one of the bows of the top, the opposite end of each curtain-holder having detachable connection with another of the bows of the top, whereby said curtain-holders may be lowered, and curtains carried by said holders.

2. In combination, a carriage-top embodying a plurality of bows, a curtain-holder pivotally connected at one end with one bow, and detachably connected at its other end with a second bow, and a curtain carried by said holder.

3. In combination, a carriage-top embodying front and rear bows, a curtain-holder pivoted at one end to the upper end portion of the rear bow, means for detachably connecting the front end of the curtain-holder with the upper portion of the front bow, and a curtain carried by said holder.

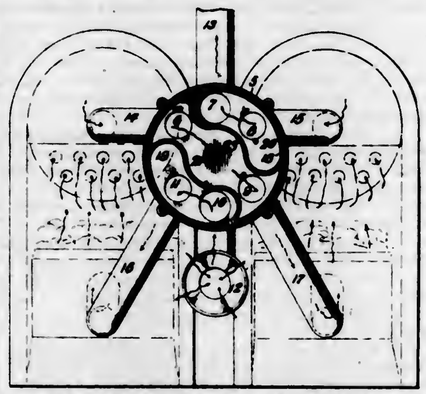
4. In combination, a carriage-top embodying front and rear bows, a curtain-holder arranged at the upper portion of the top and connected with said front and rear bows, means admitting of lowering and holding said curtain-holder in a lowered position, and a curtain carried by said holder.

5. In combination, a carriage-top embodying a plurality of bows, curtain-holders arranged at opposite sides of the top, each curtain-holder having pivotal connection with the upper end of a side of the rear bow, a catch at the upper end of each side of the front bow adapted to coact with the other end of the adjacent curtain-holder to hold the same in operative position, but admitting of lowering the holder to permit collapsing of the top, and catches arranged to engage ends of the curtain-holders after the same have been lowered, and curtains carried by said holders.

6. In combination, a carriage-top embodying a plurality of bows, a curtain-holder comprising a bar pivoted at one end to one bow and detachably connected at its opposite end to a second bow, a curtain-holder mounted upon said bar, and a curtain carried by said holder.

7. In combination, a carriage-top embodying front and rear bows, a curtain-holder comprising a bar pivoted at one end to the upper end portion of a side of the rear bow, means for detachably connecting the opposite end of said bar with the front bow, and means for detachably connecting said opposite end of the bar to the lower portion of the rear bow after said bar has been lowered.

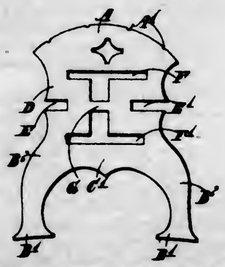
809,458. SMOKE-CONSUMING FURNACE. WALLACE T. PAXSON, Washington, D. C., assignor, by direct and mesne assignments, to Jacob B. Maxwell, Washington, D. C. Filed Apr. 28, 1905. Serial No. 257,204.



Claim.—1. In a smoke-consuming furnace, furnaces positioned side by side, a pipe leading from the smoke-space of each furnace, a valve-casing into which said pipes open, a revoluble valve mounted in the casing and formed with oppositely-positioned chambers and a passage between the chambers, downdraft-pipes leading from the valve-casing into the opposite furnaces under the grates thereof, and means to turn the valve to cut off and establish communication between determined pipe-openings in the casing.

2. The combination with adjacently-positioned furnaces the pipes 14 and 15 leading from the smoke-spaces in the furnaces, the draft-pipes 12, 13, and the downdraft-pipes 16, 17, of an inclosed revoluble valve into which all said pipes open, said valve being adapted to cut off and to establish communication between determined pipe-ports, a shaft to turn the valve and extended to the front of the furnace, an arm on the end of the shaft provided with a handle, and a graduated dial over which the arm turns.

809,459. BRIDGE FOR STRINGED MUSICAL INSTRUMENTS. REGINALD H. PAYNE, Aylesbury, England. Filed Dec. 5, 1904. Serial No. 235,539.



Claim.—1. A bridge for a stringed musical instrument having resilience increasing gradually from one side to the other.

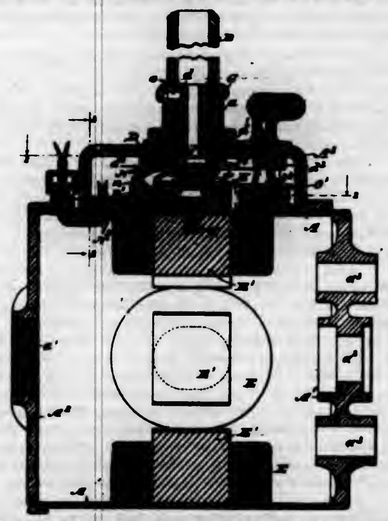
2. A bridge for stringed instruments comprising a string-bearing bar unsupported between its ends and a pair of resilient supporting members, one at each end of the bar, having different resiliency.

3. A bridge for stringed musical instruments comprising a string-bearing bar A, and members D D' supporting the bar at its ends, and differing in resiliency substantially as set forth.

4. A bridge for a stringed musical instrument comprising a string-bearing bar A, members D D' supporting the bar at its ends, and of different resiliency, and a connecting-bar C between the members substantially as set forth.

809,460. MOTOR-CONTROLLER. ADOLPH PRIESMEYER, Cleveland, Ohio, assignor to The Van Dorn-Iliett Electric Company, Cleveland, Ohio, a Corporation of Ohio. Filed May 26, 1905. Serial No. 262,262.

Claim.—1. In motor-controllers, the combination with an electric motor; of a circuit for its armature connections; means for automatically breaking said circuit when the magnetic flux of the motor reaches a predetermined quantity; and a manually-operable switch-disk adapted, when it is actuated to its "off" position, to close the break in the circuit made by said automatically-operating means.



2. In motor-controllers, the combination with an electric motor; of a circuit for its armature connections; means for automatically breaking said circuit when the magnetic flux of the motor reaches a predetermined quantity; a manually-operable switch-disk adapted, when it is actuated to its "off" position, to close the break in the circuit made by said automatically-operating means; and a short-circuiting switch included in said circuit and rendered operative during the actuation of said switch-disk to its "on" position.

3. In motor-controllers, the combination with an electric motor; of a circuit for its armature connections; a solenoid included in said circuit; circuit-breaking means adapted to be operated by the inward stroke of the core of said solenoid, such inward stroke of said core being effected when the magnetic flux of the motor reaches a predetermined quantity; a manually-operable switch-disk adapted, when it is actuated to its "off" position, to close the break in the circuit made by said circuit-breaking means; and means for effecting the outward stroke of said core.

4. In motor-controllers, the combination with an electric motor; of a circuit for its armature connections; a solenoid included in said circuit; circuit-breaking means adapted to be operated by the inward stroke of the core of said solenoid, such inward stroke of said core being effected when the magnetic flux of the motor reaches a predetermined quantity; a manually-operable switch-disk adapted, when it is actuated to its "off" position, to close the break in the circuit made by said circuit-breaking means; means for effecting the outward stroke of said core; and a short-circuiting switch included in said circuit and rendered operative during the actuation of said switch-disk to its "on" position.

5. In motor-controllers, the combination with an electric motor; of a circuit for its armature connections; means for automatically breaking said circuit when the magnetic flux of the motor reaches a predetermined quantity; a rotatory short-circuiting switch included in said circuit; a series of fixed contact-clips supporting said switch; manually-operable switching means adapted, when they are actuated to their "off" position, to close the break in the circuit made by said automatically-operating means, the actuation of said manually-operable switching means effecting the rotation of said short-circuiting switch, the latter contacting with said clips during the actuation of the switching means to their "on" position, so as to render said short circuit operative.

6. In motor-controllers, the combination with an electric motor; of a circuit for its armature connections; means for automatically breaking said circuit when the magnetic flux of the motor reaches a predetermined quantity, including a solenoid, a core therefor, a pivoted lever connected at one end to said core, a knife-switch, and switch-poles, said knife-switch held to engagement with the other end of said lever and held to contact with said switch-poles, when said core is in its outermost position; means for effecting the outward stroke of said core; and a manually-operable switch-disk adapted, when it is actuated to its "off" position, to close the break in the circuit made by said automatically-operating means.

7. In motor-controllers, the combination with an electric motor; of a circuit for its armature connections; means for automatically breaking said circuit when the magnetic flux of the motor reaches a predetermined quantity, including a solenoid, a core therefor, a pivoted lever connected at one end to said core, a knife-switch, and switch-poles, said knife-switch held to engagement with the other end of said lever and held to contact with said switch-poles, when said core is in its outermost position; means for effecting the outward stroke of said core; a manually-operable switch-disk adapted, when it is actuated to its "off" position, to close the break in the circuit made by said automatically-operating means; and a short-circuiting switch included in said circuit and rendered operative during the actuation of said switch-disk to its "on" position.

8. In motor-controllers, the combination with an electric motor; of a circuit for its armature connections; means for automatically breaking said circuit when the magnetic flux of the motor reaches a predetermined quantity, including a solenoid, an adjustable core therefor, a pivoted lever connected at one end to said core, a pivoted element held to engagement with the other end of said lever, when said core is in its outermost position, two switch-poles, and a knife-switch connected to said pivoted element and normally held by the latter to contact with said switch-poles; means for effecting the outward stroke of said core; and a manually-operable switch-disk adapted, when it is actuated to its "off" position, to close the break in the circuit made by said automatically-operating means.

9. In a portable electrically-operated drill, the combination of an electric motor provided with a suitable casing; a drill-spindle mounted in the latter; gearing connecting said motor and spindle; a manually-operable controller for said motor; and means for automatically actuating said controller to assume the "off" position when the magnetic flux of the motor reaches a predetermined quantity.

809,461. KETTLE AND LID SECURING AND OPERATING MEANS THEREFOR. CHARLES S. PIERCE, Duluth, Minn. Filed Apr. 24, 1905. Serial No. 257,023.

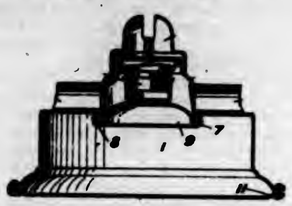
Claim.—1. The combination of a kettle or similar receptacle provided with a handle or bail having a downwardly-extending member intermediate of its ends, a kettle-lid slidably mounted on said downwardly-extending member, and a finger-hold on said lid whereby the same may be manually lifted or slid upon said rod.

2. A kettle or equivalent utensil, having a removable lid, a button mounted on said lid, a rod or bolt extending loosely through said button and lid and secured at one end to a handle provided for lifting said kettle and adapted to extend over the top of the same.

3. A kettle, or equivalent utensil, having a handle adapted to extend over the same, a rod terminating at one end at or in said handle and immovable therein and adapted to extend downwardly therefrom, a kettle-lid journaled on said rod and adapted to slide upon the same, and a finger-hold mounted on said lid whereby the same may be manually lifted, or slid upon said rod.

4. The combination of a kettle, a lid for the same, a button mounted upon said lid, a thimble projected through said button and lid and secured in such position, a swinging handle adapted to extend over said kettle, a rod or bolt terminating at one end at or in said handle and immovable therethrough and extending at the opposite end loosely through said thimble, and lid-retaining means engaging said rod or bolt at the opposite side of said lid from said handle, substantially as described.

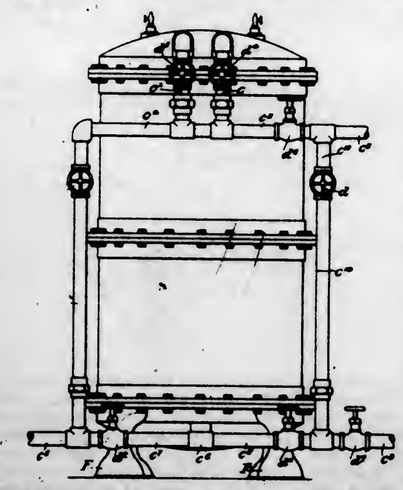
809,462. LANTERN. ALBERT R. PRITCHARD, Rochester, N. Y. Filed Sept. 22, 1905. Serial No. 279,027.



Claim.—1. The combination of a font having an opening in its upper surface provided with a downwardly-turned flange, and an air-chamber having an edge fitting within and against said flange and provided with side openings for the air-tubes of the lantern, the said two edges being rolled together whereby the said side openings are brought into registry with the top of the font when the said two edges are rolled together.

2. The combination of a font having an opening in its upper surface provided with a downwardly-turned flange, an air-chamber having an edge fitting within and against said flange and provided with side openings for the air-tubes of the lantern, the said two edges being rolled together whereby the said side openings are brought into registry with the top of the font when the said two edges are rolled together, and a burner-support having an edge rolled in with the edges of the font and of the air-chamber.

809,463. FILTER. ELLWOOD W. ROBERTS, Philadelphia, Pa., assignor, by mesne assignments, to Roberts Manufacturing Company, Incorporated, a Corporation of New Jersey. Filed May 26, 1903. Serial No. 158,866.



Claim.—1. A filter consisting of a casing containing filtering material, said casing including a portion having a partition extending across it and a head also having a partition placed to form a continuation of the partition in the first portion, said casing being provided with an inlet and an outlet for liquid to be filtered substantially as described.

2. A filter-casing, containing filtering material having a head with a vertical partition extending across the same and a body portion to said casing having a partition formed in continuation of the partition in the head, with means for forming a joint between said two partitions, said casing being provided with an inlet and an outlet for liquid to be filtered substantially as described.

3. A filter consisting of a casing containing filtering material including a substantially cylindrical section or sections and a head-section, one of the cylindrical sections having a vertical partition extending across it and the head-section also having a partition formed in continuation of the first partition, said casing being provided with an inlet and an outlet for liquid to be filtered substantially as described.

4. A casing for a filter, the same containing filtering material consisting of two sections each having a partition, one of said partitions being formed with a recess for the reception of the end of the other partition so as to form a substantially continuous surface therewith, said casing being provided with an inlet and an outlet for liquid to be filtered substantially as described.

5. A filter-casing containing filtering material, said casing including two sections each having a partition, one of said partitions being formed with a recess and the end of the other partition being tapered and adapted to enter the recess, with packing for said recess, said casing being provided with an inlet and an outlet for liquid to be filtered substantially as described.

6. A filter having openings for the entrance and exit of fluid and including a plurality of sections, certain of the same having partitions provided with means for forming a relatively tight joint between them, with filtering material filling the same below the portions having the partitions and partially filling the sections on both sides of said partitions, substantially as described.

7. A filter provided with openings for the entrance and exit of fluid and consisting of a plurality of sections including a head, said sections being mounted one upon the other, partitions extending vertically above one another across a plurality of the upper sections, and having means for forming a relatively tight joint between their adjacent ends, with filtering material in the lower portion of the filter below the partitions, said material extending into the portions of the filter on both sides of the partitions, substantially as described.

8. A casing for a filter, the same containing filtering material, including sections having partitions extending across them in substantially the same plane, the end of one of the partitions being enlarged and recessed, packing in said recess, said enlarged end being placed to receive the end of the partition of the other section, said end of the other section being sharpened along the edge contacting with the packing, said casing being provided with an inlet and an outlet for liquid to be filtered substantially as described.

9. A filter-casing having a partition in its lower portion provided with filtering material, said partition having an opening or series of openings through it with a plurality of perforated covers for each of said openings, each of said covers coacting with the other so that said covers are retained in position over the openings, said covers being of material curved to project beyond the surface of the partition, said casing having openings for the entrance and exit of fluid treated, substantially as described.

10. A filter-casing having a partition in its lower portion, said partition having an opening or a series of openings through it with a plurality of perforated covers for each of said openings, the covers being formed of curved material and one of the same having a portion extending above the partition and the other projecting below said partition, said casing containing filtering material and being provided with openings for the entrance and exit of fluid treated, substantially as described.

11. A casing having a partition extending across it, said partition being provided with openings each of which is surrounded by annular recesses in both the upper and lower faces of the partition, with two perforated covers for each opening, said covers having portions entering the recesses and means for holding the covers in position, said casing containing filtering material and being provided with openings for the entrance and exit of fluid treated, substantially as described.

12. A casing having a partition extending across it, said partition having a series of openings, each of which is surrounded by annular recesses, there being a recess in the upper and one in the lower face of the partition, two perforated covers for each opening, each extending into one of the recesses and projecting from opposite sides of the partition, and a bolt for connecting said covers, said casing containing filtering material and being provided with openings for the entrance and exit of fluid treated, substantially as described.

13. In a filter, the combination of a casing, having openings for the entrance and exit of fluid treated, a partition having a series of openings and extending across the lower portion of the casing, a pair of perforated covers of curved material projecting beyond the surface of the partition for each opening, one projecting above and the other below said partition, means for holding said covers in position and granular material confined between each pair of said covers, substantially as described.

14. In a filter, the combination of a casing, having openings for the entrance and exit of fluid treated, a partition extending across said casing and provided with openings, a pair of similar perforated covers for each of the openings projecting from opposite faces of the partition, means for holding said covers in position, means for making a tight joint between the edges of the covers and the partition, and granular material between each pair of covers, substantially as described.

15. A filter-casing containing filtering material in combination with a perforated partition across the same, said casing having a surface for the reception of the said partition, packing between the said surface and the partition, the edge of the partition being beveled so that the portion thereof nearest the center engages the packing before the portion farther from said center, said casing having openings for the entrance and exit of fluid substantially as described.

16. A filter-casing consisting of a plurality of sections, one of said sections having a surface for the reception of a ring of packing, a partition extending across the casing, packing on said surface for engagement by the edge of the partition, said edge being formed to force the packing outwardly from the center thereof, openings through said partition, perforated covers for said openings and a body of filtering material carried upon said partition, said casing having openings for the entrance and exit of fluid substantially as described.

17. A filter-casing having a vertically-placed partition extending across it and provided with an opening in its wall extending on both sides of said partition, filtering material in the casing with a plate of transparent material covering said opening and means for forming a tight joint between itself and the edge of the partition and the side of the casing, said casing having openings for the entrance and exit of fluids under treatment substantially as described.

18. A filter-casing having a partition extending across its upper portion and provided with an opening extending on both sides of said partition, filtering material in the casing, a plate of glass closing said opening, with means for projecting light into the casing, said casing having openings for the entrance and exit of fluids under treatment substantially as described.

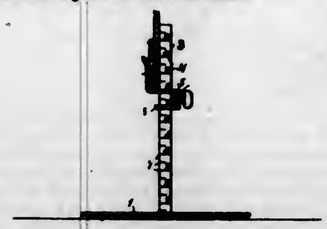
19. A filter-casing having a partition extending across its upper portion and provided with an opening extending on both sides of said partition, filtering material in the casing, a plate of glass closing said opening, and a mirror supported so as to be capable of projecting light into the casing on either side of the partition, said casing having openings for the entrance and exit of fluids under treatment substantially as described.

20. A filter-casing having a partition extending across its upper portion and provided with an opening extending on both sides of said partition, filtering material in the casing, a plate of glass closing said opening, and a mirror hinged to the casing so as to be free to swing in a position which will make it possible to project light into the casing on either side of the partition, said casing having openings for the entrance and exit of fluids under treatment substantially as described.

21. A casing having a partition extending across it, and provided with an opening extending on both sides of the partition, filtering material in the casing, a plate of glass closing said opening, and packing between the wall of the casing and the plate and between the edge of the partition and the plate with means for retaining said plate in position, said casing having openings for the entrance and exit of fluids under treatment substantially as described.

22. A casing having a partition extending vertically across it and provided with an opening extending on either side of said partition, filtering material in the casing, a plate of glass covering said opening, a frame hinged in a line substantially coincident with the plane of the vertical partition and a mirror carried in said frame so as to be free to project light into the casing on either side of the partition, said casing having openings for the entrance and exit of fluids under treatment, substantially as described.

809,464. DRESS OR SKIRT GAGE. IDA M. ROUSE, Kansas City, Mo. Filed Aug. 1, 1905. Serial No. 272,263.



Claim.—1. In a skirt-gage, the combination with a base, of a vertical standard mounted thereon, a skirt-support comprising a U-shaped body having the two parallel arms disposed horizontally one above the other, said arms having perforations respectively through which the standard extends, the body being vertically slidable upon the standard, and one of the arms of the body being provided with means for engaging and holding the lower edge of a part of a skirt.

2. In a skirt-gage, the combination with a base, of a vertical graduated standard mounted thereon, a skirt-support comprising a U-shaped body having the two parallel arms disposed horizontally one above the other, the arms being vertically slidable upon the standard, one arm being disposed so as to indicate the graduations on the standard and provided with means for engaging and holding the lower edge of a part of a skirt, and releasable means for securing the said body to the standard.

3. In a skirt-gage, the combination with a base, of a vertical standard mounted thereon, a skirt-support comprising a U-shaped body the parallel arms of which are disposed horizontally one above the other and slidable vertically on the standard, one arm having means for engaging and holding the lower edge of a part of a skirt, and the vertical part of the U-shaped body having a transverse screw-threaded hole, and a securing-screw mounted in said threaded hole in the body and adapted to bear against the standard.

4. In a skirt-gage, the combination with a base, of a vertical standard mounted thereon and having a series of transverse graduations, a skirt-support comprising a U-shaped body the parallel arms of which are disposed horizontally one above the other and slidable vertically each upon the standard, one arm having means for engaging and holding the lower edge of a part of a skirt and disposed so as to indicate the graduations on the standard, the vertical portion of the U-shaped body having a transverse screw-threaded hole, and a securing-screw mounted in said threaded hole and adapted to bear against said standard.

5. In a skirt-gage, the combination with a base, of a vertical standard mounted thereon, a skirt-support comprising a U-shaped body the parallel arms of which are disposed horizontally one above the other and slidable vertically upon the standard, one arm having thereon an upwardly-extending arm between which and the standard the skirt is adapted to be held, the vertical portion of the body connecting the horizontal arms having a transverse screw-threaded hole, and a securing-screw mounted in said hole and adapted to bear against the standard.

6. In a skirt-gage, the combination with a base, of a vertical standard mounted thereon and having a series of transverse graduations, a skirt-support comprising a U-shaped body the parallel arms of which are disposed horizontally one above the other and slidable vertically upon the standard, one of said arms having an upwardly-extending arm between which and the standard the lower edge of a skirt is adapted to be held, the arm having the upwardly-extending arm being disposed so as to indicate the graduations, the vertical portion of the U-shaped body connecting the parallel arms having a transverse threaded hole, and a securing-screw mounted in said hole and adapted to bear against the standard.

7. In a skirt-gage, the combination with a base, of a vertical standard mounted thereon, a skirt-support comprising a U-shaped body having the parallel arms disposed horizontally one above the other and slidable vertically upon the standard, one arm having an upwardly-extending resilient arm between which and the standard the lower edge of a skirt is adapted to be held, the vertical portion of the body connecting the parallel arms having a transverse screw-threaded hole, and a securing-screw fitted in said hole and adapted to bear against said standard.

8. In a skirt-gage, the combination with a base, of a vertical standard mounted thereon and having a series of transverse graduations, a skirt-support comprising a U-shaped body the parallel arms of which are disposed horizontally one above the other and slidable vertically on said standard, one arm being disposed so as to indicate the graduations and having extending upwardly therefrom a resilient arm between which and the standard the lower edge of the skirt is adapted to be held, the vertical portion of the body connecting the parallel arms having a transverse screw-threaded hole, and a securing-screw mounted in said hole and adapted to bear against the standard.

809,465. SKIRT-FASTENER. WILLIAM D. ROY and EDWARD H. ROY, Nashville, Tenn. Filed Mar. 18, 1905. Serial No. 250,575.

Claim.—A garment-fastener comprising a plate adapted to be

secured to the garment part and provided upon its outer side with a longitudinal open-ended socket or housing forming a keeper, one of

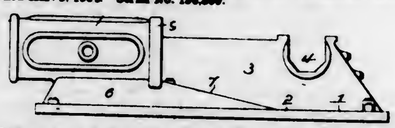
3. A connecting-link for a drop-handle, comprising a skeleton link having an opening at one end to receive the handle and another

ing a cutting-jaw and cheeks on each side of said jaw between which said jaw moves to cut both ends of the cheroot, substantially as de-

tween which said jaw is movable, a pivoted plate against which the cheroot is pressed by said jaw, means for imparting a lateral motion

secured to the garment part and provided upon its outer side with a longitudinal open-ended socket or housing forming a keeper, one of the open end portions of the keeper being transversely enlarged to provide a flared mouth, a lock-plate adapted for attachment to a second garment part and coöperating with the keeper aforesaid when forced into the mouth of the latter, teeth arranged longitudinally of the lock-plate, a side of the keeper being provided with an opening, a lock-pawl disposed exterior of the keeper at a side thereof and pivoted to the outer side of the plate carrying said keeper, said lock-pawl having one end passing through the opening in the side of the keeper to engage the teeth of the lock-plate, a finger-piece for the pawl, a spring between the pawl and the adjacent outer side of the keeper to normally hold the pawl in engagement with the teeth of the lock-plate, and a projection extended from the lock-plate near an end thereof to limit the movement of the same in introducing it into the keeper or socket.

809,466. **ENGINE-BED.** FREDERICK W. SALBOH, Burlington, Iowa, assignor to Murray Iron Works Company, Burlington, Iowa. Filed Mar. 3, 1904. Serial No. 196,369.



Claim.—1. A single casting comprising a continuous horizontal base, a longitudinal web located to one side of the longitudinal axis of the base and extending approximately from end to end of the base and provided at one end with a recess for a shaft-bearing, an enlargement rising from said horizontal base and disposed at one side of and integral with said web, and a guide-barrel upon said enlargement, said guide-barrel integral with the said enlargement and with the longitudinal web and the longitudinal web rising upwardly from the base above the axis of the guide-barrel and above the axis of the shaft-bearing.

2. A single casting comprising a continuous base, a longitudinal web located to one side of the longitudinal axis of the base and terminating at one end in a solid enlargement extending laterally from said web to a point approximating the opposite side of the base and a guide-barrel integral with said enlargement at the opposite side of the base from the web, the end of the web farthest removed from said enlargement having a recess for the reception of a bearing for a crank-shaft, said longitudinal web extending upwardly from the base and beyond the axis of the guide-barrel and above the axis of the bearing of the crank-shaft.

809,467. **DROP-HANDLE FOR COFFINS.** GEORGE A. SCHERR, Cincinnati, Ohio. Filed Jan. 27, 1905. Serial No. 242,576.

Claim.—1. In a drop-handle, the combination of the handle proper, skeleton links by which the same is supported, projections near each end of these links, sheet-metal ornamental shells having perforations adapted to receive the projections on the links after being bent over and around them to cover the same and attaching-brackets to which these links are pivotally connected.

2. An independent attaching-bracket for a drop-handle, made of sheet metal and consisting of lugs to receive the pivotal connection of the handle, a base from which these lugs project in one direction and flanges projecting from said base in an opposite direction, they being intended and adapted to rest with their edges directly against the object to which the drop-handle is to be secured.

3. A connecting-link for a drop-handle, comprising a skeleton link having an opening at one end to receive the handle and another opening at its other end to receive a pivot-pin a sheet-metal shell of limited and even thickness to cover this link and means to attach one to the other.

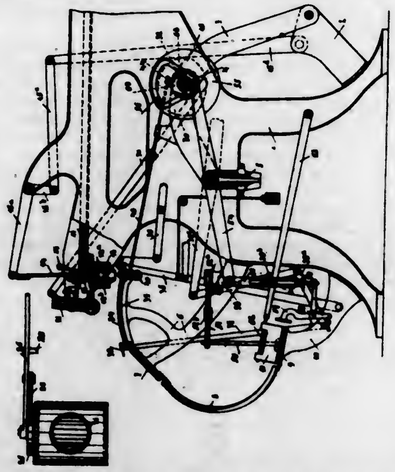
4. In a drop-handle, the combination of the handle proper, links one at each end thereof which receive each at one of their ends the handle and are provided at their other ends with an opening adapted to receive a pivot-pin, an attaching-bracket for each link adapted to be connected to the side of the coffin and provided with two projecting lugs spaced to receive between them the perforated end of a link and also provided with a corresponding opening to receive a pivot-pin and with curved slots concentric with this opening, and pins at each connected end of the links, one passing through the openings in the lugs and in the link between them and the other seated in the link and projecting from each side thereof and extending into the slots of the adjacent lugs, whereby a twofold and positive connection is provided for each link to its attaching-bracket.

809,468. **FLEXIBLE ELECTRICAL CONDUCTOR.** GEORG E. SCHMIDGEN, Nuremberg, Germany. Filed May 4, 1904. Serial No. 207,859.

Claim.—1. The herein-described product consisting of an inner or central flexible core and an outer conducting-cord wound about the core in spaced helical convolutions the said cord being composed of a central flexible core and a conductor wound about said core in close helical convolutions.

2. The herein-described product consisting of a core and an outer conducting-cord wound about the core in spaced helical convolutions, the said cord being composed of a flexible core and conductor wound about the said core in helical convolutions.

809,469. **MACHINE FOR THE PRODUCTION OF CHEROOTS.** JOHANN R. SCHMITT, Frankfort-on-the-Main, Germany, assignor to Maschinenfabrik für Tabakindustrie Gesellschaft mit Beschränkter Haftung, Frankfort-on-the-Main, Germany. Filed Jan. 11, 1905. Serial No. 240,601.



Claim.—1. In a machine for the production of cheroots and the like, the combination with a pressing device receiving loose tobacco, said pressing device comprising a rammer and a movable table having an opening through which the bunch is free to fall, means for moving said rammer, of a rolling-apron beneath said table, means for applying the wrapper to the bunch, a chute and a cutting device to which the cheroot is led by said chute, said cutting device comprising a cutting-jaw and cheeks on each side of said jaw between which said jaw moves to cut both ends of the cheroot, substantially as described.

2. In a machine for the production of cheroots and the like, the combination with a pressing device receiving loose tobacco, said pressing device comprising guides, table mounted in said guides, a rammer adapted to move between said guides, said table and said rammer being concaved corresponding to the form of the bunch, means for moving said table, means for moving said rammer, of means for applying the wrapper to the bunch, a chute, and a cutting device to which the cheroot is led from said chute and adapted to cut both ends of the cheroot simultaneously, substantially as described.

3. In a machine for the production of cheroots and the like, the combination with a pressing device receiving loose tobacco, said pressing device comprising guides, a table mounted in said guides, a rammer reciprocated between said guides, said table and said rammer being concaved corresponding to the form of the bunch, and said table having an opening through which the bunch is ejected onto the rolling-apron, means for moving the table, means for imparting a two-stage downward movement to the rammer so as first to press the tobacco, and when the table has moved to bring the opening beneath said rammer to force the bunch through said opening, the rolling-apron, means for applying the wrapper to the bunch, a chute, and a cutting device to which the cheroot is brought through said chute, and adapted to cut both ends of the cheroot simultaneously.

4. In a machine for the production of cheroots and the like, the combination with a pressing device receiving loose tobacco, said pressing device comprising a pivoted plate, a spring pressing on said plate and serving to give preliminary pressure to the tobacco, a rammer, a movable table having an opening through which the bunch is free to fall, means for moving said rammer, of a rolling-apron beneath said table, means for applying the wrapper to the bunch, means for supplying paste to the wrapper, a chute and a cutting device to which the cheroot is led by said chute, said cutting device comprising a cutting-jaw, cheeks on each side of said jaw between which said jaw moves to cut both ends of the cheroot and a pivoted plate against which the cheroot is pressed by said jaw, substantially as described.

5. In a machine for the production of cheroots and the like, the combination with a pressing device receiving loose tobacco, said pressing device comprising a moving rammer and a moving table of a rolling-apron beneath said table and receiving the bunch from said table, means for applying the wrapper to the bunch, means for delivering paste to the wrapper, said paste-delivering means comprising a vertically-movable paste-container, a drum rotatably mounted on said container and formed with grooves, and means for rotating said drum to release the paste, a chute, and a cutting device to which the cheroot is led from said chute, substantially as described.

6. In a machine for producing cheroots and the like, the combination with a pressing device of a rolling-apron receiving the bunch from said pressing device, means for applying the wrapper to the bunch, means for supplying paste to the wrapper, said paste-supplying means comprising a paste-containing cylinder, means for reciprocating said cylinder, a grooved drum carried by said cylinder, a ratchet-wheel coaxial with said drum, a pawl turning said ratchet-wheel, a lever to which said pawl is pivoted and means for oscillating said lever, a chute, and a cutting device to which the cheroot is led from said chute, substantially as described.

7. In a machine for the production of cheroots and the like, the combination with a pressing device, of means for applying the wrapper to the bunch, a chute through which the cheroot is fed to the cutting device, and means for cutting the ends of the cheroot simultaneously, said cutting means comprising a cutting-jaw the length of which corresponds to the length of the cheroot, two cheeks between which said jaw is movable, and means for moving said jaw between said cheeks so as to cut both ends of the cheroot, substantially as described.

8. In a machine for the production of cheroots and the like, the combination with a pressing device of means for applying the wrapper to the bunch, a chute through which the cheroot is led to the cutting device and said cutting device comprising a cutting-jaw 46, a pivoted plate 62 against which the cheroot is pressed by said jaw, and cheeks between which said jaw is moved to cut the ends of the cheroot simultaneously.

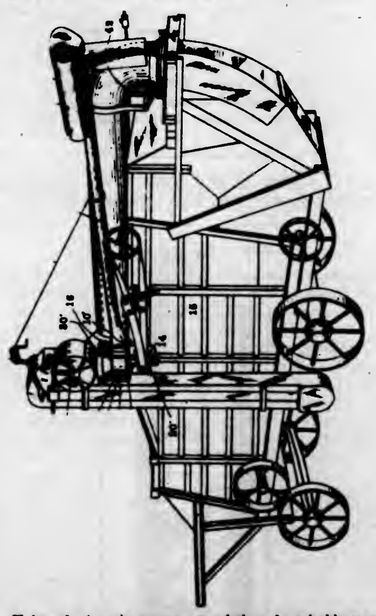
9. In a machine for the production of cheroots and the like, the combination with a pressing device of means for applying the wrapper to the bunch, a chute through which the cheroot is led to the cutting device, said cutting device comprising a cutting-jaw, cheeks between which said jaw is movable, a pivoted plate against which the cheroot is pressed by said jaw, means for imparting a lateral motion to said plate, and means for raising said plate, substantially as described.

10. In a machine for the production of cheroots and the like, the combination with a pressing device, of means for applying a wrapper to the bunch, a chute through which the cheroot is led to the cutting device, said cutting device comprising a cutting-jaw, cheeks between which said jaw is movable, a pivoted plate 62 against which the cheroot is pressed by said jaw, means for imparting a lateral motion to said plate, and means for raising said plate, substantially as described.

11. In a machine for the production of cheroots and the like, the combination with a pressing device of means for applying a wrapper to the bunch, a chute through which the cheroot is led to the cutting device, said cutting device comprising a cutting-jaw and cheeks through which said jaw is moved, a pivoted plate against which the cheroot is pressed by the cutting-jaw, a plate 57 serving to position the cheroot in front of said jaw, a lever serving to move said cutting-jaw, and means connecting said lever with said plate 57 so as to operate said jaw and said lever from the same point, substantially as described.

12. In a machine for the production of cheroots and the like the combination with a pressing device of means for applying a wrapper to the bunch, a chute leading the cheroot to the cutting device, said cutting device comprising a cutting-jaw, cheeks between which said jaw is moved a pivoted plate 61 against which the cheroot is pressed by said jaw, a plate 57 serving to position the cheroot in front of said jaw, a lever 54 actuating the cutting-jaw, a link 60 connecting said lever with said plate 57, and a lever 63 carrying the plate 61 and having a pin entering a slot in said link 60, in order on the movement of said lever 54 to raise said plate 61 periodically, as described.

809,470. **GRAIN-CONVEYER.** JAMES B. SCHUMAN, Indianapolis, Ind., assignor of three-fourths to Augustin Boice, Indianapolis, Ind. Filed Dec. 13, 1904. Serial No. 236,494.



Claim.—1. A grain-conveyer consisting of a suitable support, a drum journaled thereon, a discharge-spout communicating with said drum and hinged thereto to swing in a plane at an angle to the plane of the drum, means for holding said spout in various positions of adjustment, a throwing-wheel mounted in said drum, a door arranged in the entrance to said drum, and means for automatically opening and closing said door.

2. A grain-conveyer consisting of a drum, a discharge-spout leading therefrom, a throwing-wheel arranged in said drum, a hop-

per loading to said throwing-wheel, a door for closing said hopper, and speed-controlled means dependent upon the speed of the throwing-wheel for determining the position of the door.

3. A grain-conveyer consisting of a receiver, a spout leading therefrom, means for driving the grain through said receiver and spout, a door normally closing entrance to said receiver, and speed-controlled means dependent upon the speed of the grain-driving means for opening and closing said door.

4. The combination, with a threshing-machine, and a grain-elevator, of a grain-conveyer consisting of a drum journaled on a suitable support so as to swing in a horizontal plane beneath the discharge-point of the elevator, a discharge-spout hinged to said drum, the arrangement being such that the discharge end of the spout may be carried to either side of the thresher, and a throwing-wheel arranged in said drum.

5. A grain-conveyer consisting of a suitable support, a drum journaled thereon to swing in a horizontal plane, a discharge-spout communicating with said drum and hinged thereto to swing in a plane at an angle to the plane of the drum, means for holding said spout in various positions of adjustment, a throwing-wheel mounted in said drum, a door closing entrance to said drum, and speed-controlled means carried by the throwing-wheel for automatically operating said door.

6. A grain-conveyer consisting of a receiver, a throwing-wheel mounted therein, a hopper leading into said throwing-wheel, a door arranged to close said hopper, a brake-annulus pivoted on said hopper, interacting portions between said door and said annulus for determining the position of the door, and speed-controlled brake-arms carried by the throwing-wheel and adapted to engage the annulus.

7. In a grain-conveyer, the combination, with a spout and means for driving grain therethrough, of a honeycomb structure arranged in said spout at the point of change of direction therein to receive a limited quantity of grain upon which subsequently-arriving grain will impinge.

8. The combination, with a threshing-machine, of a grain-elevator arranged to receive the threshed grain and elevate the same above the top of the thresher, a grain-conveyer consisting of a drum journaled on a suitable support to swing in a horizontal plane below the discharge of the grain-elevator, a throwing-wheel arranged therein, and a discharge-spout attached to said drum in a plane above the top of the thresher whereby the discharge end of said spout may be swung to the opposite side of the thresher over the top thereof.

809,471. **WATER OR FLUID GAGING TUBE.** GORHAM T. SHAWBURY, Cheyenne, Wyo. Filed Feb. 7, 1905. Serial No. 244,632.

Claim.—1. In a water or fluid gaging tube, a tube of any suitable non-transparent material, provided with a plurality of apertures arranged in any predetermined order along the length of said tube; a nipple threaded to each aperture; a transparent disk seated in said nipple; and a ring-shaped cap arranged to removably secure said transparent disk to said nipple.

2. In a water or fluid gaging tube, the combination of a metal tube adapted to water-gage-valve fittings, and provided with a plurality of threaded apertures arranged in vertical rows along its length, with a plurality of nipples removably threaded to said apertures; a cap-ring threaded to the outer end of said nipple; and a glass disk arranged to be clamped between said cap-ring and said nipple.

3. In a water or fluid gaging tube, the combination of a tube, through its operative gaging body portion, having round end portions, adapted to be operatively mounted in water-gage valves, and provided with a plurality of independent and renewable light and sight inlet eyelet-windows arranged to admit light to the interior of said tube, and arranged along the length of said tube, said windows comprising nipples threaded to said tube, a cap-ring threaded to each of said nipples, a pliable washer in said cap-ring, and a glass disk secured between said nipple and washer and said cap-ring.

4. In a water or fluid gaging tube, a tube adapted to be connected to water-gage-valve fittings provided with guard-rods; a pair of curved plates loosely hinged to said guard-rods, and arranged to fold over said tube.

5. In a water or fluid gaging tube, the combination of the tube operatively connected to water-gage fittings, provided with guard-rods, and provided with a plurality of light and sight inlet eyelet-windows, with a hood comprising two curved plates each of which is hinged to one of said guard-rods and arranged to swing and overlappingly fold over said tube; means including lugs for locking said hood-plates in a folded position.

6. In a water or fluid gage, the combination with the gaging-tube, the valve-fittings, the guard-rod plates, and the guard-rods, with a hood arranged to fold over said tube and comprising a pair of curved plates, one of each of which is pivotally hinged to a guard-rod, to swing and fold together around said tube; an outward-curved lip on the free edge of one of said plates, provided with a stepped shoulder; apertures in said lip, and lugs on the edge of the opposite plate, adapted to enter said apertures, when said plates are folded over said tube, and lock said plates together.

7. In a water or fluid gaging tube, an operative gaging-tube, provided with guard-rods and one or more curved plates pivotally connected to said guard-rods and arranged to be folded around said tube.

809,472. **COMPOSITION OF MATTER.** BENJAMIN C. SEWTON, Rutland, Vt., assignor to Sexton and Evans, New York, N. Y., a Copartnership. Filed Apr. 6, 1904. Serial No. 201,836.

Claim.—A composition of matter comprising tin, zinc and aluminium with chlorid of sodium in substantially the following proportions: twelve parts of tin, two parts of zinc, one part of aluminium and one per cent. of chlorid of sodium.

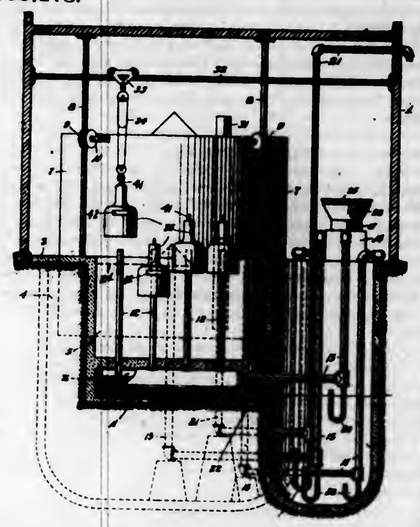
809,478. **ACETYLENE-GAS PLANT.** WILLIAM J. STIBBON, Minneapolis, Minn. Filed Dec. 2, 1904. Serial No. 236,178.

Claim.—1. In a gas-generating plant of the character described, the combination with an underground basin and gas-generating means coöperating therewith, of a gasometer having an underground well, an underground dry well and gas-conveying pipes leading from the said gas-generating means, through said dry well, and to said gasometer, substantially as described.

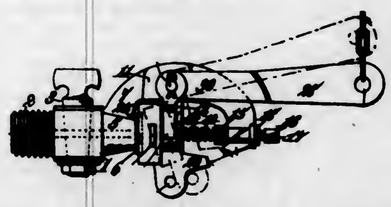
2. The combination with a generating-basin having concrete walls and base, of a gas-reservoir embedded in the concrete bottom of said basin and provided with a plurality of stand-pipes extending upward through said basin, detachable gas-generators coöperating with the upper ends of said stand-pipes, and a gasometer receiving from said embedded gas-reservoir, substantially as described.

3. The combination with a generating-basin and a supporting-ledge, of a stand-pipe extending upward through said basin, a storage-reservoir receiving from said stand-pipe, a generating-dome provided within with a carbid-holder, telescopically engageable over said stand-pipe, said dome having a laterally-projecting supporting-flange coöperating with said supporting-ledge to hold said dome with its lower end closed by the water in said basin, but with its carbid-holder out of contact therewith, substantially as described.

809,478.



809,474. **WATER-GAGE MECHANISM.** THOMAS STRINGER, Girard, Ohio. Filed Mar. 3, 1905. Serial No. 248,314.



Claim.—1. In a device of the class set forth, the combination with a tap having an open end, of a carrier pivotally supported adjacent to the open end of the tap and located exteriorly of the latter, the said carrier being transversely disposed with respect to the tap, a flexible occluder removably held on a portion of the carrier to engage the open end of the tap, exteriorly-located resilient means for automatically closing the carrier and occluder and exerting a pressure force on the said carrier in longitudinal alinement with the tap, and devices for releasing the occluder and simultaneously moving the carrier, said devices providing two independent points for opening the occluder and moving the carrier therewith.

2. In a device of the class set forth, the combination with a tap having an open end surrounded by a flange, of a depending carrier pivotally supported at its upper extremity by and located wholly exteriorly of the tap and provided with a flexible occluder coöperating directly with the open end of the tap, the occluder having a recess to inclose the flanged open end of the tap, and adjustable resilient means for automatically closing the carrier and occluder carried by the latter and exerting a longitudinal pressure on the carrier, and a pivoted lever device having depending members embracing and loosely engaging opposite portions of the carrier to open the latter against the resistance of the resilient means.

3. In an attachment of the class set forth, the combination with a tap having an open extremity, of a carrier pivotally supported by and exteriorly of the tap and provided with a yielding occluder to engage the open extremity of the tap, the said carrier being disposed in a plane at right angles to the position of the tap, an adjustable resilient means bearing against the outer side of the carrier and exerting a longitudinal pressure on the latter and the occluder to hold the occluder normally closed against the open extremity of the tap, and means coöperating with the carrier to swing the latter and the occluder outwardly away from the tap against the resistance of the said resilient means.

4. In an attachment of the class set forth, the combination with a tap, of a depending pivotally-mounted carrier having an occluder to coöperate with a part of the tap and also provided with a lower terminal operating means, an adjustable device for automatically closing the carrier and occluder, and an operating-lever having depending members bearing against opposite portions of the carrier.

5. In an attachment of the class set forth, the combination of a tap having an open extremity provided with an outwardly-projecting bracket, a carrier movably depending from said bracket, and having an occluder to coöperate with the extremity, an adjustable closing-spring interposed between the outer end of the bracket and the carrier, the spring exerting a direct longitudinal pressure against the carrier and occluder, and means for opening the carrier against the resistance of the spring.

6. In an attachment of the class set forth, the combination of a tap having a bracket projecting outwardly therefrom and terminating at its free end in a stop projection, a carrier movably depending from the bracket and having an occluder thereon to engage a portion of the tap, the carrier also having a stop projection to engage that on the bracket, a spring interposed between the outer end of the bracket and carrier for automatically closing the carrier, and means for opening the carrier against the resistance of the spring.

7. In an attachment of the class set forth, the combination of a tap having a bracket projecting outwardly therefrom, a carrier movably depending from the bracket, an occluder removably held on a part of the carrier to engage the tap, a key extending through the occluder and part of the carrier with which it engages, and devices for opening and closing the carrier and occluder.

8. In an attachment of the class set forth, the combination of a tap having supporting means projecting outwardly therefrom, a carrier movably depending from the supporting means and having an occluder to engage a part of the tap the outer terminal of the supporting means projecting beyond the carrier, an adjusting-screw mounted in the outer terminal of the supporting means, a spring connected at opposite extremities to the carrier and screw, the spring exerting a direct longitudinal pressure against the carrier and occluder, and means for opening the carrier against the resistance of the spring.

9. In an attachment of the class set forth, the combination of a tap having supporting means projecting outwardly therefrom and terminating in a seat and a stop device, a carrier movably depending from the supporting means and having an occluder to engage one terminal of the tap and also provided with a stop projection to contact with the stop device of the supporting means, an adjusting-screw mounted in the seat of the supporting means, a spring connected at opposite extremities to the carrier and screw, and means for opening the carrier against the resistance of the spring.

809,475. **MOTOR-VEHICLE.** THOMAS L. STURTEVANT, Quincy, and THOMAS J. STURTEVANT, Wellesley, Mass., assignors to Sturtevant Mill Company, Portland, Me., a Corporation of Maine. Filed June 6, 1905. Serial No. 263,987.

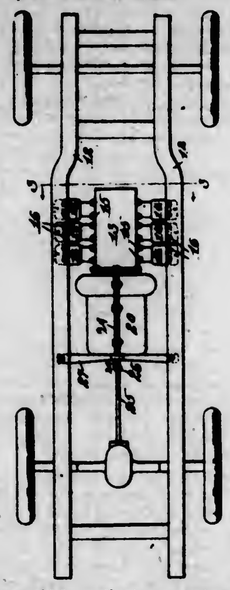
Claim.—1. In a motor-vehicle, the combination with a vehicle-frame comprising side beams, of an opposed-cylinder engine-frame arranged crosswise of said vehicle-frame and forming a rigid transverse part of said vehicle-frame, said engine-frame being disposed between the front and rear axles of the vehicle and with the cylinder portions of said engine-frame inside of or between the outside parts of said side beams and approximately central, vertically, of the said side beams.

2. In a motor-vehicle, the combination with a vehicle-frame comprising side beams, of an opposed-cylinder engine-frame arranged crosswise of said vehicle-frame between the front and rear axles of the vehicle and with the cylinder portions of said engine-frame approximately central, vertically, of the said side beams, and with the horizontal inlet and exhaust valves of the engine located below the said side beams.

3. In a motor-vehicle, the combination with a vehicle-frame comprising side beams, of an opposed-cylinder engine-frame arranged crosswise of said vehicle-frame between the front and rear axles of the vehicle and with the cylinder portions of said engine-frame approximately central, vertically, of the said side beams, and having sparking plugs mounted on the upper portions of the cylinders of the engine-frame.

4. In a motor-vehicle, a chassis or vehicle frame comprising side beams, combined with an opposed-cylinder engine-frame form-

ing a rigid transverse part of said vehicle-frame and supported by said side beams and between the outside parts of the latter, with the axes of the cylinder portions of the engine-frame between the lines of the upper and lower parts of said side beams.



5. In a motor-vehicle, a chassis or vehicle frame comprising side beams, combined with an opposed-cylinder engine-frame forming a rigid transverse part of said vehicle-frame and arranged crosswise the chassis and supported by and within the outer faces or parts of said side beams, with the axes of the cylinder portions of the engine-frame between the lines of the upper and lower parts of said side beams, said engine-frames supporting horizontal inlet and exhaust valves which are disposed below the lower lines of the said side beams.

6. In a motor-vehicle, a chassis or vehicle frame comprising side beams, combined with an opposed-cylinder engine-frame forming a rigid transverse part of the vehicle-frame and arranged crosswise the chassis and connected with said side beams, with the axes of the cylinder portions of the engine-frame between the lines of the upper and lower parts of said side beams, and sparking plugs mounted on the upper portions of the engine-cylinders.

7. In a motor-vehicle, the combination with a chassis or vehicle frame, of a horizontal, opposed-cylinder explosion engine or motor supported by said chassis or frame and arranged crosswise of the latter with its cylinder portions laterally between the outer faces or parts of the side beams of said frame, so that the said side beams can assist in resisting the shock of the explosions of the said engine or motor, and with the inlet and exhaust valves of the said engine or motor below the said side beams.

8. In a motor-vehicle, the combination with a chassis or vehicle frame, of a horizontal, opposed-cylinder explosion engine or motor supported by said chassis or frame and arranged crosswise of the latter with its cylinder portions laterally between the outer faces or parts of the side beams of said frame, so that the said side beams can assist in resisting the shock of the explosions of the said engine or motor, and with the sparking plugs of the said engine or motor mounted upon the upper parts of the said cylinders.

9. In a motor-vehicle, the combination with a chassis or vehicle frame, of a horizontal, opposed-cylinder explosion engine or motor supported by said chassis or frame and arranged crosswise of the latter with its cylinder portions laterally between the outer faces or parts of the side beams of said frame, so that the said side beams can assist in resisting the shock of the explosions of the said engine or motor, and with the inlet and exhaust valves of the said engine or motor below the said side beams, and also with the sparking plugs of the said engine or motor mounted upon the upper parts of the said cylinders.

10. In a motor-vehicle, the combination with a chassis or vehicle frame comprising two angular-flanged side beams of inverted-L shape in cross-section, of an opposed-cylinder explosion engine or motor arranged crosswise of the said frame and hung from the upper flanges of the said side beams and having the axes of its cylinders between the lines of the upper and lower parts of the said side beams, so that the latter are adapted to resist shocks of explosions of the said engine or motor with a minimum tendency to twist the said side beams.

11. In a motor-vehicle, the combination with a chassis or vehicle frame comprising two angular-flanged side beams of inverted-L shape in cross-section, of an opposed-cylinder explosion engine or motor arranged crosswise of the said frame and hung from the upper flanges of the said side beams and having the axes of its cylinders between the lines of the upper and lower parts of the said side beams, so that the latter are adapted to resist shocks of explosions of the said engine or motor with a minimum tendency to twist the said side beams, the inlet and exhaust valves of the said engine or motor being below the said side beams and the sparking plugs of the said engine or motor being mounted upon the upper portions of said cylinders.

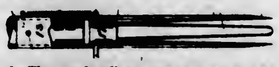
12. In a motor-vehicle, the combination with a chassis or vehicle frame, of an explosion engine or motor supported on said frame crosswise of the latter, with its cylinder portions between the upper and lower lines of the said side beams, a clutch and gearing casing rearward of the engine-frame, a driving-shaft in said clutch and gearing casing in line with the engine-shaft, a working shaft in said clutch and gearing casing below the said driving-shaft and geared thereto, and a power-transmitting shaft connected with said working shaft and approximately in line with the latter.

13. In a motor-vehicle, the combination with a chassis or vehicle frame, of an engine or motor frame, a gear-casing rigid with and partly supported by said motor-frame, a driving or power shaft connected with the engine or motor, a power-transmitting or working shaft below and geared to the said power-shaft and having its bearings in said casing, and through which latter shaft power is communicated to the driving-wheels of the vehicle.

14. In a motor-vehicle, the combination with a chassis or vehicle frame, of an engine or motor frame, a gear-casing rigid with and partly supported by said motor-frame, a driving or power shaft connected with the engine or motor, a power-transmitting or working shaft below and geared to the said power-shaft and through which latter shaft power is communicated to the driving-wheels of the vehicle, and an automatic clutch within said casing.

15. In a motor-vehicle, the combination with a chassis or vehicle frame, of an engine or motor frame, a gear-casing rigid with and partly supported by said motor-frame, a driving or power shaft connected with the engine or motor, a power-transmitting or working shaft below and geared to the said power-shaft and through which latter shaft power is communicated to the driving-wheels of the vehicle, an automatic clutch and a fly-wheel both within said casing.

809,476. **WEED-PULLER.** PAUL M. THAYER, Plymouth, Ind. Filed July 26, 1904. Serial No. 217,906.



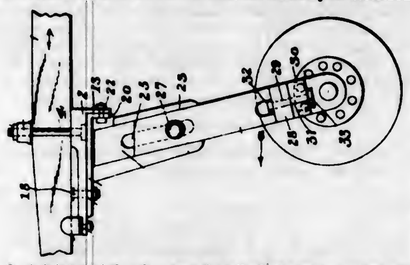
Claim.—1. The weed-puller consisting of a handle and a series of pointed sharp-edged knives attached thereto and made of spring metal so as to adapt them to yield convergingly when pressed into the ground.

2. The implement herein described, consisting of a handle and a series of pointed and sharp-edged knives arranged in a small circle around the bottom of the handle, the implement being adapted to insert the knives in the ground and to be turned after insertion so as to effect a clean severation of the surrounding dirt and lateral roots and enable the easy extraction of the weed.

809,477. **DISK JOINTER FOR PLOWS.** PERCY R. THORNE and RAYMOND D. WELTON, Vincennes, Ind. Filed May 26, 1905. Serial No. 262,263.

Claim.—1. A jointer of the character described comprising upper and lower attaching-plates, means for clamping said upper plate to the plow-beam, means whereby said plates are connected together to permit them to be adjusted laterally, a depending arm arranged on said lower plate, a jointer-standard adjustably secured to said arm, and a disk jointer detachably connected to the lower end of said standard, substantially as described.

2. A jointer of the character described comprising an upper attaching-plate, adjustable clamping-bolts to secure the forward end of said plate to the plow-beam, adjustable clamping-bars to secure the rear end of said plate to the beam, a downwardly-projecting right-angularly-disposed, horizontally-slotted extension formed on the forward edge of said upper plate, a transversely-slotted lower attaching-plate adjustably connected to said upper plate, a depending obliquely-disposed arm formed integrally with said lower attaching-plate, said arm having formed therein a longitudinally-disposed channel and a longitudinally-disposed slot, a jointer-standard adjustably mounted in said channel, a bolt adapted to pass through said standard and through the slot in said arm to adjustably secure said standard to said arm, and a disk jointer adapted to be secured to the lower end of said standard, substantially as described.



3. A jointer of the character described comprising upper and lower attaching-plates, means for clamping said upper plate to the plow-beam, means whereby said plates are connected together to permit them to be adjusted laterally, a depending arm arranged on said lower plate, a jointer-standard adjustably secured to said arm, an apertured enlargement formed on the lower end of said standard, a right-angularly-formed bearing-bracket secured to said enlargement, a jointer-shaft arranged in said bracket, and a disk jointer secured on said shaft, substantially as described.

4. A jointer of the character described comprising upper and lower attaching-plates, means for clamping said upper plate to the plow-beam, means whereby said plates are connected together to permit them to be adjusted laterally, a depending arm arranged on said lower plate, a jointer-standard adjustably secured to said arm, an apertured enlargement formed on the lower end of said standard, said enlargement having a roughened lower surface, a right-angularly-formed bearing-bracket, having a roughened upper surface to engage the roughened surface of said enlargement, an attaching-bolt adapted to be passed through the aperture in said enlargement and an alined aperture in said bracket, a horizontally-disposed bearing-box arranged in said bracket, a jointer-shaft mounted in said box, a bushing arranged between said shaft and said boxing, a plate secured to said shaft, near one end of the same, a nut adapted to be screwed on the other end of the shaft, a disk jointer arranged on the end of said shaft adjacent to said plate, bolts to secure said disk to said plate, and a nut adapted to be screwed on the end of said shaft against the outer face of said disk, substantially as described.

809,478. **TRUCK.** PATRICK TWOMEY, New York, N. Y. Filed Feb. 11, 1905. Serial No. 245,941.

Claim.—1. A truck comprising a frame having uprights, a platform mounted at the upper extremities thereof, cross-bars connecting the uprights, pairs of wheels upon which the frame is supported, and a steering-shaft journaled in the cross-bars and connected with one of the pairs of wheels, said steering-shaft terminating below the platform.

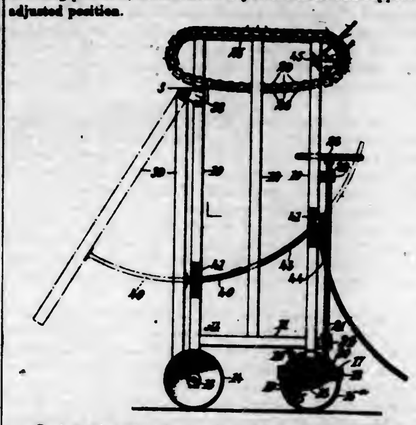
2. A truck comprising a wheeled frame having opposite ways and provided with downwardly and inwardly curved end portions.

3. A truck comprising a wheeled frame having opposite ways, an endless series of connected bars movable over the ways, and a locking device movable between the bars.

4. A truck comprising a wheeled frame, a conveyer mounted upon the frame and furnishing a platform, and a chute pivoted upon the frame below one extremity of the conveyer.

5. A truck comprising a wheeled frame having supporting-ways, a flexible, endless traveling platform having its upper run movable over the ways, and means to lock said flexible platform against movement.

6. A truck comprising a wheeled frame having elevated supporting-ways, a flexible, endless traveling platform having its upper run movable over the ways, a chute having its upper end pivotally connected to the frame at a point below the discharge portion of the traveling platform, and means to adjust the chute and support it in adjusted position.



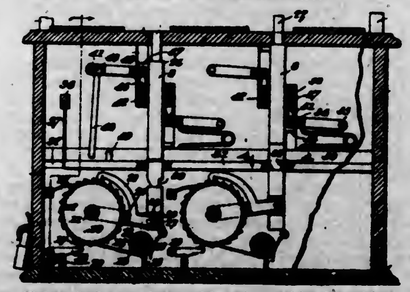
7. A truck comprising a wheeled frame having elevated supporting-ways, a flexible, endless traveling platform having its upper run movable over the ways, a chute having its upper end pivotally connected to the frame at a point below the discharge portion of the traveling platform, and means to adjust the chute and support and lock it in adjusted position.

8. A truck comprising a wheeled frame, an elevated platform mounted thereon, a chute pivoted upon the frame, and an operating member including two sections, one of which is connected with the chute and the other pivoted to the first-named section, each of said sections having retaining means which may engage the frame.

9. A truck comprising a wheeled frame, an elevated platform supported thereon, a chute having its upper end pivoted to one side of the frame, under one end of the platform, and curved operating-bars pivotally connected together and pivotally connected to the chute, said frame having guides through which said operating-bars extend, and said bars having stops to coact with said guides to lock the bars to the frame and secure the chute in adjusted position.

10. A truck comprising a wheeled frame having guide-openings in its front and rear sides, an elevated platform supported on said frame, a chute having its upper end pivoted to one side of the frame under the discharge portion of the platform, and curved operating-bars pivotally connected together and pivotally connected to the chute, said operating-bars extending through the guide-openings in the frame and having stop devices to coact with the sides of said openings to lock said bars and hence said chute in adjusted position.

809,479. **VOTING-MACHINE.** CLARENCE M. WARNER, Cambridge, Ill. Filed Apr. 20, 1905. Serial No. 256,260.



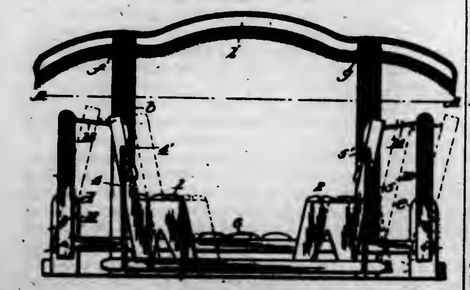
Claim.—1. In a voting-machine, the combination with a cabinet, of a series of key-guideways and a series of slide-guideways disposed at substantially right angles to the key-guideways, a series of keys mounted in the guideways and provided at their front sides with corresponding locking-notches and at their rear sides with cor-

responding inclined notches, and a series of locking-slides mounted in the slide-guideways, each slide having its forward end bifurcated to straddle the adjacent key and lie in engagement with the rear end of the next in front slide, the back of each bifurcation being inclined and normally engaging the inclined notch of the adjacent key, the rear end of each slide being alined with and in front of the locking-notch of the adjacent key, each key being provided with shoulders located respectively above and below the adjacent locking-slide for contact therewith to limit movement of the key in opposite directions.

2. In a voting-machine, a series of slidable voting-keys provided in corresponding sides with notches and at their opposite corresponding sides with cams, and a series of locking-slides having their ends successively abutted and their forward ends bifurcated to straddle the respective keys, the backs of the bifurcations being normally in engagement with the respective cams, and each slide being movable under the influence of the adjacent cam to move the slide into engagement with the notch of the next adjacent key to lock the same, the bifurcation of each slide being of a length to receive the adjacent key throughout the movement of the slide in opposite directions.

3. In a voting-machine, a series of slidable voting-keys provided in corresponding sides with notches and at their opposite corresponding sides with cams, and a series of locking-slides having their ends successively abutted and their forward ends notched to receive the respective keys with the backs of the notches normally in engagement with the respective cams, each slide being movable under the influence of the adjacent cam to move said slide into engagement with the notch of the next adjacent key to lock the same, and each key being provided with shoulders at opposite sides of the adjacent locking-slide for contact therewith to limit the depression and the elevation of the key.

809,480. LAWN-SWING. HENRY W. WATSON, Danville, Ky., assignor of one-fourth to Henry C. Bright, Danville, Ky. Filed July 31, 1905. Serial No. 272,168.



Claim.—1. A lawn-swing having, in combination, a supporting-frame, a pair of seats and a seat-frame common to both movable together horizontally but rigidly connected with each other, a horizontally-movable foot-platform, swinging supports for said seats and said platform respectively having axes of motion parallel with each other, and means for transmitting motion from said platform to said seats.

2. A lawn-swing having, in combination, a supporting-frame, a pair of vis-à-vis seats and a seat-frame common to both movable together horizontally but rigidly connected with each other, a horizontally-movable foot-platform between said seats, swinging supports for said seats and said platform respectively having axes of motion parallel with each other, and means for transmitting motion from said platform to said seats.

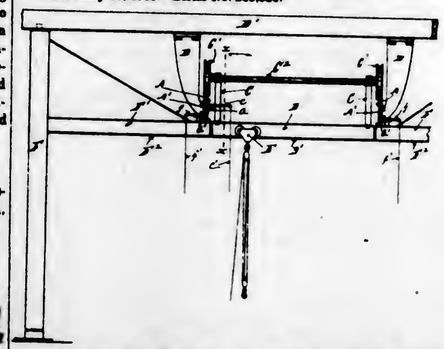
3. A lawn-swing having, in combination, a supporting-frame, a pair of seats and a seat-frame common to both movable together horizontally but rigidly connected with each other, a horizontally-movable foot-platform, swinging supports for said seats and said platform respectively having axes of motion parallel with each other, and means for transmitting motion from said platform to said seats, the platform and seats moving at each impulse in opposite directions.

4. A lawn-swing having, in combination, a supporting-frame, a pair of seats and a seat-frame common to both movable together horizontally but rigidly connected with each other, a horizontally-movable foot-platform, swinging supports for said seats and said platform respectively having axes of motion parallel with each other, and motion-increasing devices for transmitting motion from said platform to said seats.

5. A lawn-swing having, in combination, a supporting-frame, a seat-frame movable horizontally, a horizontally-movable foot-platform, swinging supports for said seat-frame and platform respectively having axes of motion parallel with each other, and motion-increasing devices transmitting motion from said platform to said seat-frame the two moving at each impulse in opposite directions.

6. A lawn-swing having, in combination, a supporting-frame, a pair of vis-a-vis seats having upwardly-extending backs with side bars and a seat-frame common to both seats movable together horizontally but rigidly connected with each other, a horizontally-movable foot-platform, swinging supports for said seat-frame and said platform respectively having axes of motion parallel with each other the supports of said platform being in the form of lever-frames interacting therewith below their pivots and having side bars located behind those of the respective seats and extended above their pivots to any desired extent, and motion-transmitting links connecting the upper ends of the side bars of said lever-frames with those of the seats, respectively, substantially as hereinbefore specified.

809,481. CRANE MECHANISM. JOHN R. WHITTEMORE, Erie, Pa. Filed May 16, 1905. Serial No. 260,330.



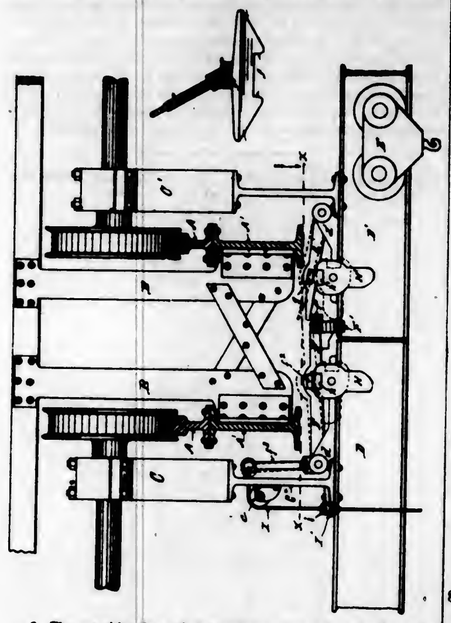
Claim.—1. The combination of a traveling crane, a transverse horizontal trolley-track thereon, a jib-crane on one side of the line of travel of the traveling crane, a horizontal trolley-track thereon on the same horizontal plane with the trolley-track on the traveling crane, means for locking the jib-crane trolley-track at right angles to the line of travel of the traveling crane, means for locking the traveling crane so that the trolley-track thereon will coincide with the trolley-track on the jib-crane when it is at right angles to the line of travel of the traveling crane, and a trolley-hoist adapted to operate over both of said trolley-tracks when they coincide as aforesaid and pass from one to the other, substantially as set forth.

2. The combination of a traveling crane, tracks therefor supported from above, a transverse horizontal track on said crane below the track-support thereof, a series of jib-cranes on one or both sides of the traveling-crane supports, horizontal trolley-tracks on said jib-cranes on the same horizontal plane with the trolley-track on the traveling crane, means for locking each of said jib-cranes at right angles to the track-support of the traveling crane, latch mechanism for locking the traveling crane in line with each of said jib-cranes when at right angles with the track-support so that the trolley-track on the traveling crane will coincide with the trolley-track on the jib-crane opposite thereto, and a trolley-hoist adapted to travel over the trolley-track on the traveling crane and the trolley-track on the jib-crane coinciding therewith, and from one to the other, substantially as set forth.

809,482. CRANE-LOCKING MECHANISM. JOHN R. WHITTEMORE, Erie, Pa. Filed June 5, 1905. Serial No. 264,695.

Claim.—1. In a locking device for cranes, a locking-lever pivoted to one crane and adapted to engage another crane, a trolley-hoist stop adapted to be engaged by the locking-lever, and means for operating the locking-lever, substantially as set forth.

2. In a locking mechanism for cranes, a locking-lever pivoted to the trolley-hoist track of one crane, and adapted to engage the trolley-hoist track of another crane, a lever-latch on said other crane adapted to be engaged and raised by said locking-lever, trolley-hoist stops secured to both trolley-hoist crane-tracks, means on said locking-lever and said lever-latch for engaging and locking said stops, and means for raising said locking-lever, substantially as set forth.



3. The combination of two cranes, transverse trolley-hoist tracks on both of said cranes adapted to be brought into coincidence, a locking-lever pivoted on the trolley-hoist track of one crane and projecting beyond the end thereof, inclined lateral projections on the end of the locking-lever having a slot between them adapted to automatically engage the top of the trolley-hoist track of the other crane when the two cranes are brought into coincidence, a lever-latch pivoted to the top of the trolley-hoist track on the second crane adapted to be engaged and raised by the end of the locking-lever on the trolley-hoist track of the first-named crane, swinging trolley-hoist stops pivoted on the top of both trolley-hoist tracks under the locking-lever and lever-latch thereon, lugs on said locking-lever and said lever-latch adapted to engage notches in said swinging stops, and means for raising the locking-lever and the lever-latch so as to release said swinging stops without unlocking the trolley-hoist tracks from each other, substantially as set forth.

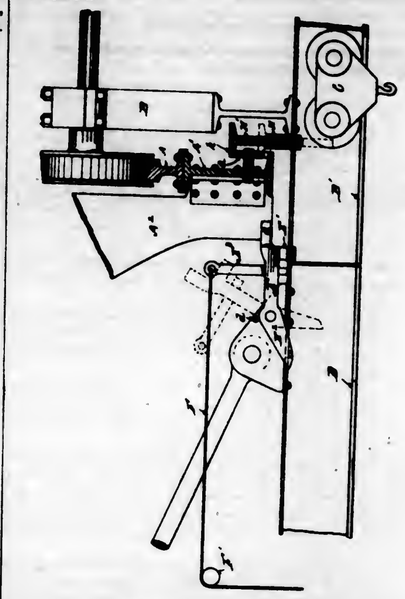
809,483. LOCKING DEVICE FOR CRANES. JOHN R. WHITTEMORE, Erie, Pa. Filed June 9, 1905. Serial No. 264,496.

Claim.—1. The combination of a traveling crane, a jib-crane, a stationary stop on the traveling-crane support, a locking-lever pivoted to the jib-crane adapted to engage said stationary stop and the traveling crane, and means for operating said locking-lever, substantially as set forth.

2. The combination in a crane, of a trolley-hoist track a trolley-hoist operative thereon, a locking-lever pivoted to said crane, an arm on said locking-lever adapted to operate as a trolley-hoist stop when the locking-lever is raised and means for raising said locking-lever, substantially as set forth.

3. The combination of a traveling crane, a trolley-hoist track thereon, a trolley-hoist operative on said track, a stop mechanism on said track, means on the traveling-crane-track support for automatically operating said stop mechanism, a stationary stop on the traveling-crane-track support, a jib-crane, a trolley-hoist track thereon, a locking-lever pivoted thereto adapted to engage said stationary stop and the trolley-hoist track on the traveling crane, and lock them together and against lateral movement, an arm on said locking-lever adapted to operate as a trolley-hoist stop when the locking-lever is raised, and means for operating said locking-lever, substantially as set forth.

809,483.



809,484. COMBINED FILE AND BINDER FOR NEWSPAPERS AND SUCH LIKE MATERIAL. JOSEPH WILSON, Christchurch, New Zealand. Filed Nov. 29, 1904. Serial No. 234,777.

Claim.—1. In a file for newspapers and the like, in combination, a narrow oblong-shaped frame, upwardly-projecting sharpened hooks secured upon the frame whereon sheets of paper are impaled, a flap that is hinged to the frame that has loops or incisions through which the hooks come when the flap is brought over the hooks in order to hold or lock the papers on the file, a guard-piece likewise hinged to the frame that is adapted to come over the points of the hooks and spring-catches on the guard-wire supports that engage with the stems of the spikes, substantially as specified.

2. In a file for newspapers, letters and such like not requiring alphabetical arrangement in which the matter filed may also be longitudinally bound, a narrow oblong-shaped frame, and three upwardly-projecting sharpened hooks on the frame, in combination with a cord that is passed through the eyes in the outer pair of hooks preparatory to placing matter on the file, and when the file is full withdrawn from the outer pair of hooks and its free ends threaded both ways respectively through the eye in the central hook and the papers withdrawn from the file, a flap that is hinged to the frame that has loops or incisions through which the hooks come when the flap is brought over the hooks in order to lock the papers on the file, a guard-piece likewise hinged to the frame that is adapted to come over the points of the hooks and spring-catches upon the guard-wire supports that engage with the stems of the spikes, substantially as described and as illustrated.

3. A file for letters and the like requiring alphabetical arrangement, comprising a file having three spikes and curved pieces 14 adapted to engage with the ends of the spikes in which latter are eyes, in combination with a cord that is threaded through the eyes in the spikes said file being constructed so that one, two or three spikes,

may be operated independently of each other, or altogether as set forth.

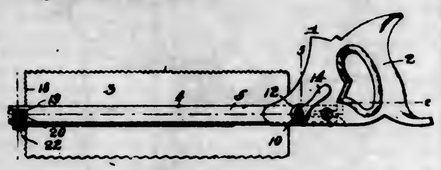
closure for the lower ends of the outer and intermediate drums and having the openings 6 between them and the opening 7 at the lower

gear-teeth upon their circumferences, a shaft, springs secured at their ends to the gear of the vehicle and to said shaft, gear-wheels

thereof, a sheave or pulley, a series of antifriction-balls arranged in each end of the hub thereof, a removable cone-bushing carried in

may be operated independently of each other, or altogether as set forth.

809,485. SAW. FREDERICK A. WEBER, Lawrenceburg, Ind. Filed Sept. 11, 1905. Serial No. 277,971.



Claim.—1. A saw having a slidably-mounted blade provided with rack-teeth along one edge, and a screw having its thread engaged with said teeth for adjusting said blade.

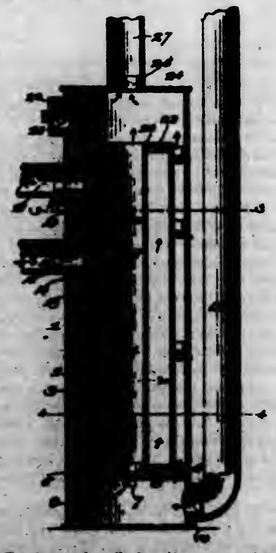
2. A saw comprising a handle, a back, a blade slidable in said back and having rack-teeth, a worm-screw having its thread engaging said rack-teeth for adjusting one end of said blade, and means for clamping the other end thereof.

3. A saw comprising a handle, a back, a blade having rack-teeth upon its outer end, a worm-screw mounted in the outer end of said back and having its thread engaged with said rack-teeth, and means for clamping the inner end of said blade.

4. A saw comprising a handle, a slotted back, a saw-blade slidable in the latter and having its outer end formed with rack-teeth, a worm-screw journaled in the recessed outer end of said back and having its thread engaged with said rack-teeth, a finger-piece for operating said worm-screw, and means for clamping the inner end of said blade.

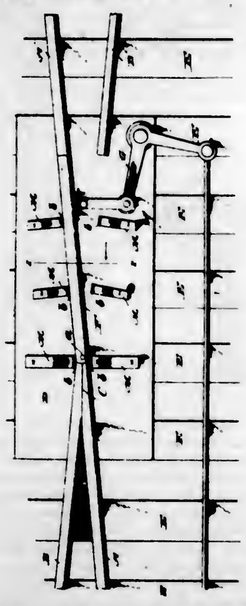
5. A saw comprising a handle formed with a recessed portion, a back consisting of two opened members connected together and recessed at their outer ends and formed with aliming longitudinal slots at their inner ends, a guide-screw in said handle extending through said slots, a clamping-bolt in said handle and extending through said slot, a blade slidable between the members of said back and having cutting-teeth on its longitudinal or side edges and rack-teeth on its outer end, a worm-screw in the recess in the outer end of said back and having its thread engaged with said rack-teeth, and a knob or finger-piece for rotating said worm-screw, substantially as described.

809,486. RADIATOR. WILLIS H. WYANT, Tabor, Iowa. Filed Mar. 6, 1905. Serial No. 248,506.



Claim.—The herein-described radiator comprising the outer drum open at its upper end, the intermediate drum in the outer drum, the inner drum in the intermediate drum, the base-plate forming a closure for the lower ends of the outer and intermediate drums and having the openings 6 between them and the opening 7 at the lower end of the inner drum, the top plate forming a closure for the upper end of the intermediate drum and having the central opening through which the upper end of the inner drum extends, the smoke-flue connections 15, 20, extending from the intermediate drum through one side of the outer drum, the downwardly-directed deflector in the space between the intermediate and inner drums and having the horizontally-disposed upper portion closing said space on one side of the inner drum, disposed between the flue connections and having an opening, and the damper to cover and uncover said opening.

809,487. RAILWAY-FROG. THOMAS L. BERNHAM, Deward, Mich. Filed Oct. 13, 1905. Serial No. 282,581.

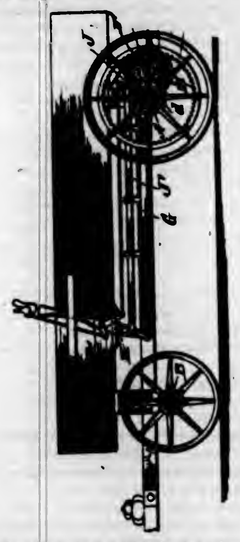


Claim.—The herein-described railway-frog, comprising sleepers or ties, the smooth bed-plate D superposed on the sleepers or ties, the rails A and B arranged on the plate D, and having their adjacent end portions reduced and brought together and fixed with respect to each other and also having a concave seat at their terminus, rails A' and B' having their ends arranged a slight distance apart and on the plate D, the horizontally-swinging point pivoted to the plate D adjacent to the terminus of rails A and B and having a head, a base and a web interposed between the head and base and also having a convex heel disposed in the said concave seat, and sets of braces arranged on and fixed to the plate D and disposed at opposite sides of the point; said braces having their inner ends shaped to snugly occupy the space between the head and base of the point.

809,488. WAGON ATTACHMENT. WRIGHT W. CAIN, Kosciusko, Miss. Filed Sept. 13, 1905. Serial No. 278,280.

Claim.—1. In combination with a vehicle having wheels mounted upon the axles thereof, the hubs of the rear axles of the vehicle having gear-teeth upon their circumferences, a shaft, springs secured at their ends to the gear of the vehicle and to said shaft, gear-wheels fixed to said shaft and adapted to be thrown into mesh with the gear-teeth of said hub, whereby said shaft may be rotated to bring said springs under tension, gear-rings fastened to the rear wheels of the vehicle and having teeth on their inner marginal edges, gear-wheels carried by said shaft and adapted to engage the teeth of said gear-rings, and means for throwing said gear-wheels into and out of mesh with the gear-teeth upon said hubs and rings, as set forth.

2. In combination with a vehicle having wheels mounted upon the axles thereof, the hubs of the rear axles of the vehicle having gear-teeth upon their circumferences, a shaft, springs secured at their ends to the gear of the vehicle and to said shaft, gear-wheels fixed to said shaft and adapted to be thrown into mesh with the gear-teeth of said hub, whereby said shaft may be rotated to bring said springs under tension, gear-rings fastened to the rear wheels of the vehicle and having teeth on their inner marginal edges, gear-wheels carried by said shaft and adapted to engage the teeth of said gear-rings, longitudinally-movable bars in which said shaft has a bearing, and means for moving said bars, whereby said gear-wheels may be thrown into and out of mesh with the gear-teeth upon said hubs and the teeth of said rings, as set forth.



3. In combination with a vehicle having wheels mounted upon the axles thereof, the hubs of the rear axles of the vehicle having gear-teeth upon their circumferences, a shaft, springs secured at their ends to the gear of the vehicle and to said shaft, gear-wheels fixed to said shaft and adapted to be thrown into mesh with the gear-teeth of said hub, whereby said shaft may be rotated to bring said springs under tension, gear-rings fastened to the rear wheels of the vehicle and having teeth on their inner marginal edges, gear-wheels carried by said shaft and adapted to engage the teeth of said gear-rings, longitudinally-movable bars in which said shaft has a bearing, a crank-shaft mounted upon the vehicle and to which said bars are pivotally connected, a portion of said shaft forming a lever for rocking the same, and means for holding the shaft from rotation when out of gear, as set forth.

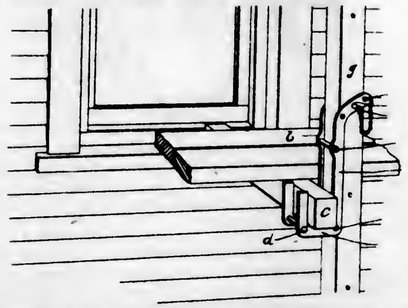
4. In combination with a vehicle having wheels mounted upon the axles thereof, the hubs of the rear axles of the vehicle having gear-teeth upon their circumferences, a shaft, springs secured at their ends to the gear of the vehicle and to said shaft, gear-wheels fixed to said shaft and adapted to be thrown into mesh with the gear-teeth of said hub, whereby said shaft may be rotated to bring said springs under tension, gear-rings fastened to the rear wheels of the vehicle and having teeth on their inner marginal edges, gear-wheels carried by said shaft and adapted to engage the teeth of said gear-rings, longitudinally-movable bars in which said shaft has a bearing, a crank-shaft mounted upon the vehicle and to which said bars are pivotally connected, a portion of said shaft forming a lever for rocking the same, a pawl riding upon one of the gear-wheels, a rod to which said pawl is connected, and a lever connected to one of said bars and to which said rod is fastened, as set forth.

809,489. SASH-PULLEY. CHARLES J. CALEY, New Britain, Conn., assignor to Russell & Erwin Manufacturing Company, New Britain, Conn., a Corporation of Connecticut. Filed July 3, 1905. Serial No. 268,073.

Claim.—1. A sash-pulley comprising a frame having a face-plate and two side arms connected thereto, with passages through said side arms and countersunk enlargements around the outer sides thereof, a sheave or pulley, a series of antifriction-balls arranged in each end of the hub thereof, a removable cone-bushing carried in the passage in each side arm, a shoulder on each bushing located in the countersunk portion of the side arm, one of said bushings having a drilled hole and the other bushing having a tapped hole, and a screw passing freely through the drilled hole of the one bushing and taking into the tapped hole in the other bushing.

2. In a sash-pulley, the combination of a frame having yielding side arms, a sheave having a series of ball-bearings at each end of its hub, removable cone-bushings seated in openings in said side arms and having shoulders abutting against the outer faces thereof, and a screw for adjusting said bushings with regard to said bearings.

809,490. SAFETY SCAFFOLD-SUPPORT. PETER CAPORALE, Hartford, Conn. Filed Sept. 29, 1905. Serial No. 280,673.



Claim.—1. In a scaffold-support the side members braced from and secured to one another, rearwardly-extending ears at the upper ends of said side members, by means of which the device may be secured in place, a U-shaped recess formed at the lower end of the device by extending the ends of said members forwardly and then upwardly, and brace-bars providing a stop to hold said U-shaped recess free from the part to which the device is attached.

2. In a scaffold-support the side arms, U-shaped on their lower ends, rearwardly-extending ears lying at each side of the scaffold-upright, brace-bars connecting the side members, and means for securing the whole to the upright.

3. A scaffold-flooring support consisting of two side members U-shaped at their lower ends, brace-bars connecting the side members, holes oppositely arranged in the upper ends of the side members, and a securing-pin adapted to pass through said holes and a hole in the upright.

4. The combination with a scaffold including uprights, floor-beams, a platform, of means secured to the uprights for securing the floor-beams, said means comprising side members, brace-bars securing said side members together, attaching-ears formed by extending the upper ends of the side members rearwardly adapted to lie one on each side of the upright, registering holes in said attaching-ears, and the upright, a pin extending through the holes in the ears and upright, the lower ends of the side members being bent forwardly and upwardly forming a recess to receive and retain said flooring-beams.

809,491. TRIPLE VALVE. ROBERT B. CHAPMAN, Colorado City, Colo. Filed Sept. 29, 1904. Serial No. 225,268.

Claim.—1. The combination with an auxiliary reservoir of an air-brake system, of a triple valve having a pipe connection connected at its end with the triple valve and reservoir and forming connection therebetween, a valve-stem guide separate from and arranged in said pipe connection, and a check-valve arranged in such connection and having a stem coöperating with such guide; substantially as described.

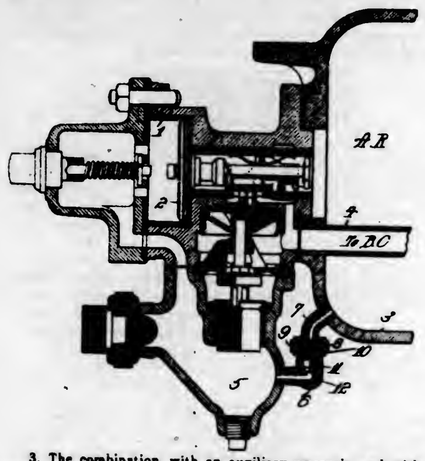
2. The combination, with a triple valve and the auxiliary reservoir 3, of a connection between the triple valve and reservoir comprising the pipes 6 and 7 joined by the union-nut 8 and communicating directly between the triple valve and reservoir, a check-valve

guide arranged in one of the pipes and clamped therein by the union-nut 8, and a check-valve 11 within the pipe 6; substantially as de-

tached pawl or dog carried by said post and fulcrumed therein and adapted to engage the inner surface of the casing, a casing secured to the

by an auxiliary weight in one direction so that the outer end of said

guide arranged in one of the pipes and clamped therein by the union-nut 8, and a check-valve 11 within the pipe 6; substantially as described.



3. The combination, with an auxiliary reservoir, and with a triple valve having a drain-cup 5, of two pipes 6, 7 communicating between such cup and the reservoir, the separate guide 9 in the pipe 6, and a check-valve 11 in such communication and guided by said guide; substantially as described.

809,492. PROCESS FOR ELECTROLYTIC PRODUCTION OF LUSTROUS METALLIC COATINGS UPON METALS. ALEXANDER CLASSEN, Aachen, Germany. Filed Sept. 28, 1905. Serial No. 280,454.

Claim.—1. The process for the production of lustrous metallic coatings on metals by electrolysis, which consists in adding to the electrolytic bath in which the metal articles are to be treated one or more glucosides.

2. The process for the production of lustrous metallic coatings on metals by electrolysis, which consists in adding to the electrolytic bath in which the metal articles are to be treated, extract of plants, or parts of plants, containing a glucoside.

3. The process for the production of lustrous metallic coatings upon metals, which consists in placing the metal to be treated in an electrolytic bath containing a glucoside, allowing the metal to remain in such bath until a lustrous metallic coating is produced thereon, and then removing the coated metal from the bath.

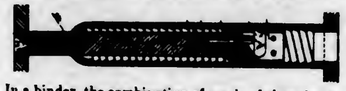
4. The process for the production of lustrous metallic coatings upon metals, which consists in placing the metal to be treated together with the metal which is to form a coating in an electrolytic bath containing extract of licorice-root, allowing the metal to remain in such bath until a lustrous metallic coating is produced thereon, and then removing the coated metal from the bath.

5. The process for the production of lustrous metallic coatings upon metals, which consists in providing an electrolytic bath composed of zinc sulfate, sodium sulfate, zinc chlorid, boric acid, water and licorice-root embraced within an electric circuit, placing the metal in such bath, allowing the metal to remain in the bath until a lustrous metallic coating is produced thereon, and then removing the coated metal from the bath.

6. The process for the production of lustrous metallic coatings upon metals, which consists in providing an electrolytic bath embraced within an electric circuit and composed of a solution of twenty kilos crystallized zinc sulfate, four kilos crystallized sodium sulfate, one kilo zinc chlorid and 0.5 kilo boric acid in one hundred liters water, adding the extract of five kilos licorice-root, placing the metal in such bath, allowing the metal to remain in the bath until a lustrous metallic coating is produced thereon, and then removing the coated metal from the bath.

809,493. BINDER. FREDERICK A. CLEVELAND, New York, N. Y. Filed May 17, 1905. Serial No. 260,788.

Claim.—1. In a binder, the combination of a pair of clamping members, a post attached to one of said clamping members, an unattached pawl or dog carried by said post and fulcrumed therein and adapted to engage the inner surface of the casing, a casing secured to the other of said clamping members adapted to telescope over said post, an auxiliary weight coöperating with said pawl or dog to accelerate the action of the same, substantially as described.



2. In a binder, the combination of a pair of clamping members, a post having a slot at the lower end thereof attached to one of said clamping members, an unattched pawl or dog carried by said post and fulcrumed therein and adapted to engage the inner surface of a casing, a casing secured to the other of said clamping members adapted to telescope over said post, an auxiliary weight coöperating with said pawl or dog to accelerate the action of the same, substantially as described.

3. In a binder, the combination of a pair of clamping members, a post having a slot at the lower end thereof attached to one of said clamping members, an unattched pawl or dog carried by said post in said slot and fulcrumed therein in such a manner that the bottom of said slot forms a stop to limit the movement of said pawl or dog, a casing secured to the other of said clamping members adapted to telescope over said post, an auxiliary weight coöperating with said pawl or dog to accelerate the action of the same, substantially as described.

4. In a binder, the combination of a pair of clamping members, a post attached to one of said clamping members, an unattached pawl or dog carried by said post and fulcrumed therein and adapted to engage the inner surface of a casing, a casing having a serrated inner surface secured to the other of said clamping members and adapted to telescope over said post, an auxiliary weight coöperating with said pawl or dog to accelerate the action of the same, substantially as described.

5. In a binder, the combination of a pair of clamping members, a post attached to one of said clamping members, an unattached pawl or dog carried by said post and fulcrumed therein and adapted to engage the inner surface of a casing, a casing having a threaded inner surface secured to the other of said clamping members and adapted to telescope over said post, means for rotating said post in said casing, an auxiliary weight coöperating with said pawl or dog to accelerate the action of the same, substantially as described.

6. In a binder, the combination of a pair of clamping members, a post having a chamber at the lower end thereof attached to one of said clamping members, an unattached pawl or dog carried by said post and fulcrumed therein and adapted to engage the inner surface of a casing, a casing secured to the other of said clamping members adapted to telescope over said post, an auxiliary weight located in said chamber in said post and coöperating with said pawl or dog to accelerate the action of the same, substantially as described.

7. In a binder, the combination of a pair of clamping members, a post having a slot at the lower end thereof, said slot being partially closed by means of a stop member secured therein, an unattached pawl or dog carried by said post in said slot and fulcrumed against said stop member and adapted to engage the inner surface of a casing, a casing secured to the other of said clamping members adapted to telescope over said post, an auxiliary weight coöperating with said pawl or dog to accelerate the action of the same, substantially as described.

8. In a binder, the combination of a pair of clamping members, a post attached to one of said clamping members, an unattached pawl or dog carried by said post and having one end thereof adapted to be fulcrumed therein and the other end thereof adapted to engage the inner surface of a casing, a casing secured to the other of said clamping members adapted to telescope over said post, an auxiliary weight coöperating with said pawl or dog to accelerate the action of the same, substantially as described.

9. In a binder, the combination of a pair of clamping members, a post attached to one of said clamping members, an unattached pawl or dog carried by said post and having one end thereof curved to fulcrum therein and the other end thereof adapted to engage the inner surface of a casing, a casing secured to the other of said clamping members adapted to telescope over said post, an auxiliary weight coöperating with said pawl or dog to accelerate the action of the same, substantially as described.

10. In a binder, the combination of a pair of clamping members, a post attached to one of said clamping members, an unattached pawl or dog carried by said post and having one end thereof formed on a circular arc to fulcrum therein and the other end thereof adapted to engage the inner surface of a casing, a casing secured to the other of said clamping members, adapted to telescope over said post, an auxiliary weight coöperating with said pawl or dog to accelerate the action of the same, substantially as described.

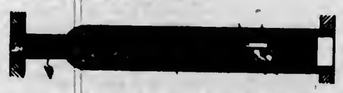
11. In a binder, the combination of a pair of clamping members, a post having a slot at the lower end thereof, said slot being partially closed by means of a stop member secured therein, a stop member having a portion thereof adapted to form a fulcrum for a pawl or dog, an unattached pawl or dog carried by said post in said slot and having one end thereof adapted to be fulcrumed against said stop member and the other end thereof adapted to engage the inner surface of a casing, a casing secured to the other of said clamping members adapted to telescope over said post, an auxiliary weight coöperating with said pawl or dog to accelerate the action of the same, substantially as described.

12. In a binder, the combination of a pair of clamping members, a post having a slot at the lower end thereof, said slot being partially closed by means of a stop member secured therein, a stop member having a portion thereof curved to form a fulcrum for a pawl or dog, an unattached pawl or dog carried by said post in said slot and having one end thereof curved to adapt it to be fulcrumed against said stop member and the other end thereof adapted to engage the inner surface of a casing, a casing secured to the other of said clamping members adapted to telescope over said post, an auxiliary weight coöperating with said pawl or dog to accelerate the action of the same, substantially as described.

13. In a binder, the combination of a pair of clamping members, a post having a slot at the lower end thereof, said slot being partially closed by means of a stop member secured therein, a stop member having a portion thereof formed on a circular arc to provide a fulcrum for a pawl or dog, an unattached pawl or dog carried by said post in said slot and having one end thereof formed on a circular arc to adapt it to be fulcrumed against said stop member and the other end thereof adapted to engage the inner surface of a casing, a casing secured to the other of said clamping members adapted to telescope over said post, an auxiliary weight coöperating with said pawl or dog to accelerate the action of the same, substantially as described.

14. In a binder, the combination of a pair of clamping members, a post having a slot at the lower end thereof, said slot being partially closed by means of a stop member secured therein, a stop member having a portion thereof formed on a circular arc to provide a fulcrum for a pawl or dog, an unattached pawl or dog carried by said post in said slot and having one end thereof formed on a circular arc to adapt it to be fulcrumed against said stop member and having at the other end thereof a projection adapted to engage coöperating projections on the inner surface of a casing, a casing having projections from the inner surface thereof adapted to engage said projection on said pawl or dog, said casing being secured to the other of said clamping members and adapted to telescope over said post, an auxiliary weight coöperating with said pawl or dog to accelerate the action of the same, substantially as described.

809,494. BINDER. FREDERICK A. CLEVELAND, New York, N. Y. Filed July 7, 1905. Serial No. 268,699.



Claim.—1. In a binder, the combination of a pair of clamping members, a post attached to one of said members, an oscillatory pawl or dog carried by said post and adapted to engage the inner surface of a casing, a casing secured to the other of said clamping members and adapted to telescope over said post, an auxiliary weight coöperating with said pawl or dog to lock the same in engagement with said casing, substantially as described.

2. In a binder, the combination of a pair of clamping members, a post having a slot at the lower end thereof attached to one of said clamping members, an oscillatory pawl or dog carried by said post in said slot and adapted to engage the inner surface of a casing, a casing secured to the other of said clamping members adapted to telescope over said post, an auxiliary weight coöperating with said pawl or dog to accelerate the action of the same, substantially as described.

3. In a binder, the combination of a pair of clamping members, a post having a slot at the lower end thereof attached to one of said clamping members, an oscillatory pawl or dog carried by said post in said slot in such a manner that the movement thereof is limited by an auxiliary weight in one direction so that the outer end of said pawl will engage the inner surface of a casing, a casing secured to the other of said clamping members and adapted to telescope over said post, an auxiliary weight coöperating with said pawl or dog to hold the same in engagement with said casing, substantially as described.

4. In a binder, the combination of a pair of clamping members, a post attached to one of said clamping members, an oscillatory pawl or dog carried by said post and adapted to engage the inner surface of a casing, a casing having a serrated inner surface secured to the other of said clamping members and adapted to telescope over said post, an auxiliary weight coöperating with said pawl or dog to lock the same in engagement with said casing, substantially as described.

5. In a binder, the combination of a pair of clamping members, a post attached to one of said clamping members, an oscillatory pawl or dog carried by said post and adapted to engage the inner surface of a casing, a casing having a threaded inner surface secured to the other of said clamping members and adapted to telescope over said post, means for rotating said post in said casing, an auxiliary weight coöperating with said pawl or dog to hold the same in engagement with said casing, substantially as described.

6. In a binder, the combination of a pair of clamping members, a post having a recess at the lower end thereof attached to one of said clamping members an oscillatory pawl or dog carried by said post in said recess and adapted to engage the inner surface of a casing, a casing secured to the other of said clamping members and adapted to telescope over said post, an auxiliary weight located in a chamber in said post coöperating with said pawl or dog to lock the same in engagement with said casing, substantially as described.

7. In a binder, the combination of a pair of clamping members, a post having a slot at the lower end thereof, an oscillatory pawl or dog pivotally attached to said post in said slot and having a portion thereof adapted to engage the inner surface of a casing, a casing secured to the other of said clamping members and adapted to telescope over said post, an auxiliary weight coöperating with said pawl or dog to lock the same in engagement with said casing, substantially as described.

8. In a binder, the combination of a pair of clamping members, a post having a slot at the lower end thereof, an oscillatory pawl or dog pivotally attached to said post in said slot having a portion thereof adapted to engage the inner surface of a casing and having a portion thereof adapted to engage an auxiliary weight to hold the same in position, a casing secured to the other of said clamping members and adapted to telescope over said post, an auxiliary weight coöperating with said pawl or dog to lock the same in engagement with said casing, substantially as described.

9. In a binder, the combination of a pair of clamping members, a post attached to one of said clamping members, an oscillatory pawl or dog pivotally attached to said post, having a portion thereof adapted to engage the inner surface of a casing and a portion thereof flattened to engage an auxiliary locking-weight, a casing secured to the other of said clamping members and adapted to telescope over said post, an auxiliary weight coöperating with said pawl or dog to lock and hold the same in engagement with said casing, substantially as described.

10. In a binder, the combination of a pair of clamping members, a post attached to one of said clamping members, an oscillatory pawl or dog pivotally attached to said post, having a portion thereof adapted to engage the inner surface of a casing and a portion thereof adapted to be engaged by an auxiliary weight, a casing secured to the other of said clamping members and adapted to telescope over said post, an auxiliary weight coöperating with said pawl or dog to hold the same in engagement with said casing and adapted to drop out of engagement with the pawl when the clamping members are reversed in position thus rendering the pawl inoperative and allowing the clamping members to be separated, substantially as described.

11. In a locking device, the combination of a pair of telescoping members, an oscillatory pawl or dog carried by the inner of said members, an auxiliary weight carried by said inner member and so located in relation to said pawl as to lock the same in an operative position and adapted to drop out of engagement with said pawl when the members are reversed in position thus rendering the pawl inoperative and allowing the telescoping members to be separated, substantially as described.

12. In a binder, the combination of a pair of clamping members, a post having a slot at the lower end thereof, an oscillatory pawl or dog pivotally attached to said post in said slot, said slot having a portion thereof forming a stop to limit the movement of said pawl in one

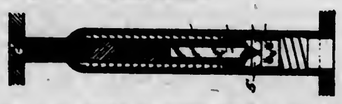
direction, an auxiliary weight located in a chamber adjacent to said slot in said post and adapted to limit the movement of said pawl in the opposite direction when the members are in one position and adapted to fall out of engagement with said pawl when the position of the members is reversed, a casing secured to the other of said clamping members and adapted to telescope over said post, substantially as described.

13. In a binder, the combination of a pair of clamping members, a post attached to one of said members, an oscillatory pawl or dog carried by said post and adapted to engage the inner surface of a casing, a casing secured to the other of said clamping members and adapted to telescope over said post, and an auxiliary member adapted to engage and lock said pawl or dog and adapted to fall out of engagement with the same when the binder is reversed.

14. In a binder, the combination of a pair of clamping members, a post attached to one of said members, an oscillatory pawl or dog carried by said post and adapted to engage the inner surface of a casing, a casing secured to the other of said clamping members, and adapted to telescope over said post, and an auxiliary member carried in a recess in said post adapted to engage and lock said pawl or dog and adapted to fall out of engagement with the same when the binder is reversed.

15. In a binder-lock, in combination, a pair of telescoping members, an oscillatory pawl or dog carried by one of said members and adapted to engage the other of said members, and an auxiliary member adapted to engage and lock said pawl or dog and adapted to fall out of engagement when the device is reversed.

809,495. BINDER. FREDERICK A. CLEVELAND, New York, N. Y. Filed July 7, 1905. Serial No. 268,660.



Claim.—1. In a binder, the combination of a pair of clamping members, a post attached to one of said clamping members, an unattached sliding pawl or dog carried by said post and adapted to engage the inner surface of a casing, a casing secured to the other of said clamping members adapted to telescope over said post, an auxiliary weight coöperating with said pawl or dog to slide the same into engagement with said casing, substantially as described.

2. In a binder, the combination of a pair of clamping members, a post having a slot at the lower end thereof attached to one of said clamping members, an unattached sliding pawl or dog carried in said slot in said post and adapted to engage the inner surface of a casing, a casing secured to the other of said clamping members adapted to telescope over said post, an auxiliary weight coöperating with said pawl or dog to slide the same into engagement with said casing, substantially as described.

3. In a binder, the combination of a pair of clamping members, a post having a slot at the lower end thereof attached to one of said clamping members, an unattached sliding pawl or dog carried by said post in said slot in such a manner that the bottom of said slot forms a stop to limit the movement of said pawl or dog, a casing secured to the other of said clamping members adapted to telescope over said post, an auxiliary weight coöperating with said pawl or dog to slide the same into engagement with said casing, substantially as described.

4. In a binder, the combination of a pair of clamping members, a post attached to one of said clamping members, an unattached sliding pawl or dog carried by said post and adapted to engage the inner surface of a casing, a casing having a serrated inner surface secured to the other of said clamping members and adapted to telescope over said post, an auxiliary weight coöperating with said pawl or dog to slide the same into engagement with said casing, substantially as described.

5. In a binder, the combination of a pair of clamping members, a post attached to one of said clamping members, an unattached sliding post or dog carried by said post and adapted to engage the inner surface of a casing, a casing having a threaded inner surface secured to the other of said clamping members and adapted to telescope over said post, means for rotating said post in said casing, an auxiliary weight coöperating with said pawl or dog to slide the same into engagement with said casing, substantially as described.

6. In a binder, the combination of a pair of clamping members, a post having a recess at the lower end thereof attached to one of said clamping members, an unattached sliding pawl or dog carried by said post in said recess and adapted to engage the inner surface of a casing, a casing secured to the other of said clamping members adapted to telescope over said post, an auxiliary weight located in a chamber in said post coöperating with said pawl or dog to slide the same into engagement with said casing, substantially as described.

7. In a binder, the combination of a pair of clamping members a post having a slot at the lower end thereof, said slot being partially closed by means of a slot member secured therein, an unattached sliding pawl or dog carried by said post in said slot adapted to slide upon said stop member and to engage the inner surface of a casing, a casing secured to the other of said clamping members and adapted to telescope over said post, an auxiliary weight coöperating with said pawl or dog to slide the same into engagement with said casing, substantially as described.

8. In a binder, the combination of a pair of clamping members, a post attached to one of said clamping members, an unattached sliding pawl or dog carried by said post and having one end thereof adapted to engage an auxiliary weight and the other end thereof adapted to engage the inner surface of a casing, a casing secured to the other of said clamping members adapted to telescope over said post, an auxiliary weight coöperating with said pawl or dog to slide the same into engagement with said casing, substantially as described.

9. In a binder, the combination of a pair of clamping members, a post attached to one of said clamping members, an unattached sliding pawl or dog carried by said post and having one end thereof beveled to engage an auxiliary weight and the other end thereof adapted to engage the inner surface of a casing, a casing secured to the other of said clamping members adapted to telescope over said post, an auxiliary weight coöperating with said pawl or dog to slide the same into engagement with said casing, substantially as described.

10. In a binder, the combination of a pair of clamping members, a post attached to one of said clamping members, a pair of unattached sliding pawls or dogs carried by said post and having the outer ends thereof adapted to engage the inner surface of a casing, a casing secured to the other of said clamping members, adapted to telescope over said post, an auxiliary weight coöperating with said pawls or dogs to slide the same into engagement with said casing, substantially as described.

11. In a binder, the combination of a pair of clamping members, a post attached to one of said clamping members, a pair of separable unattached pawls or dogs carried by said post and having the outer ends thereof adapted to engage the inner surface of a casing, a casing adapted to telescope over said post, said casing being secured to the other of said clamping members, an auxiliary weight coöperating with said pawls or dogs to separate the same and cause the outer ends thereof to engage said casing, substantially as described.

12. In a binder, the combination of a pair of clamping members, a post having a slot at the lower end thereof, said slot being partially closed by means of a stop member secured therein and having the upper portion thereof form an angle with the axis of said post, a stop member having the upper portion thereof forming a sliding surface interior of said slot, an unattached sliding pawl or dog carried by said post in said slot adapted to slide on said stop member and having the outer end thereof adapted to engage the inner surface of a casing, a casing secured to the other of said clamping members and adapted to telescope over said post, an auxiliary weight coöperating with said pawl or dog to slide the same into engagement with said casing, when the members are in the operative position and when said members are reversed in position said weight being adapted to fall out of engagement with said pawl or dog allowing it to drop out of engagement with said casing against the angular upper portion of the slot in which it is carried allowing the post and casing to be separated, substantially as described.

13. In a binder, the combination of a pair of clamping members, a post attached to one of said clamping members, said post having a recess at the lower end thereof and a chamber opening into said recess, a pair of unattached sliding pawls or dogs carried by said post in said recess and having the outer ends thereof adapted to engage the inner surface of a casing, a casing secured to the other of said clamping members and adapted to telescope over said post, an auxiliary weight carried by said post in said chamber, said weight having one end thereof wedge-shaped and adapted to engage said pawls or dogs and slide the same outwardly into engagement with said casing when the members are in the operative position and to move out of engagement with said pawls or dogs allowing the same to slide inwardly and to drop out of engagement with said casing when the members are reversed in position, substantially as described.

14. In a binder, the combination of a pair of clamping members, a post attached to one of said clamping members, said post having a slot at the lower end thereof and a chamber opening into said slot, a pair of unattached separable pawls or dogs carried by said post in said slot having the outer ends thereof adapted to engage the inner surface of a casing and having the inner ends thereof beveled to engage an operating-weight, a casing secured by the other of said clamping members and adapted to telescope over said post, an auxiliary operating-weight carried by said post in said chamber, said weight having one end thereof wedge-shaped and adapted to engage the beveled portion of said pawls or dogs and to move and to hold the same in engagement with said casing when the members are in the operative position and to move out of engagement with said pawls or dogs allowing the same to drop out of engagement with said casing when the members are reversed in position, substantially as described.

809,496. BINDER. FREDERICK A. CLEVELAND, New York, N. Y. Filed July 7, 1905. Serial No. 268,665.

Claim.—1. In a binder, the combination of a pair of clamping members, a post having a tapered shank at the lower end thereof attached to one of said clamping members, a member having a serrated surface carried by said post on said shank and adapted to engage the inner surface of a casing, a casing secured to the other of said clamping members and adapted to telescope over said post, substantially as described.

2. In a binder, the combination of a pair of clamping members, a post having a tapered shank at one end thereof attached to one of said clamping members, a member having a serrated surface carried by said post on said shank in such a manner that the movement thereof is limited in one direction so that the outer surface of said member will engage the inner surface of a casing, a casing secured to the other of said clamping members and adapted to telescope over said post, substantially as described.

3. In a binder, the combination of a pair of clamping members, a post having a conical portion at the lower end thereof attached to one of said clamping members, a semicircular member having a serrated surface carried by said post on said conical portion and adapted to engage the inner surface of a casing, a casing secured to the other of said clamping members and adapted to telescope over said post, substantially as described.

4. In a binder, the combination of a pair of clamping members, a post having a conical-shaped portion with a stop at one end thereof, a semicircular dog having a serrated surface carried by said post on said conical-shaped portion and adapted to engage the inner surface of a casing, a casing secured to the other of said clamping members and adapted to telescope over said post, substantially as described.

5. In a binder, the combination of a pair of clamping members, a post having a conical-shaped portion with a stop at one end thereof, a pair of semicircular dogs having a serrated surface carried by said post on said conical-shaped portion and adapted to engage the inner surface of a casing, a casing secured to the other of said clamping members and adapted to telescope over said post, substantially as described.

6. In a binder, the combination of a pair of clamping members, a post having a tapered shank forming a portion thereof, a semicircular dog having a serrated surface carried by said post on said tapered portion and adapted to engage the inner surface of a casing, a casing secured to the other of said clamping members and adapted to telescope over said post, substantially as described.

7. In a binder, the combination of a pair of clamping members, a post having a tapered shank forming a portion thereof a pair of semicircular dogs having a serrated surface carried by said post on said tapered portion and adapted to engage the inner surface of a casing, a casing secured to the other of said clamping members and adapted to telescope over said post, substantially as described.

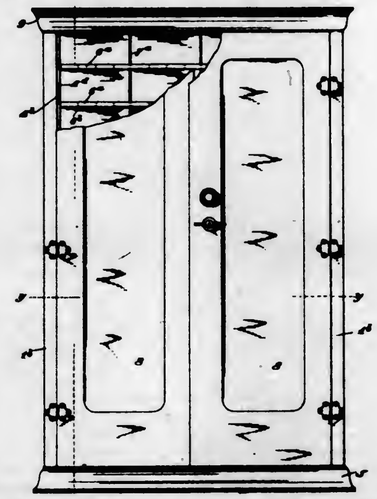
8. In a binder, the combination of a pair of clamping members, a post having a tapered shank with a stop portion at one end of said shank, a semicircular dog having a serrated surface carried by said post on said tapered portion and adapted to be operated by gravity to the larger end of said shank when the members are in one position and to engage the inner surface of a casing, a casing secured to the other of said clamping members and adapted to telescope over said post, substantially as described.

9. In a binder, the combination of a pair of clamping members, a post having a tapered shank with a stop portion at one end of said shank, a pair of semicircular dogs having a serrated surface carried by said post on said tapered portion and adapted to be operated by gravity to the larger end of said shank when the members are in one position and to engage the inner surface of a casing, a casing secured to the other of said clamping members and adapted to telescope over said post, substantially as described.

10. In a binder, the combination of a pair of clamping members, a post having a tapered shank portion, a dog having a serrated surface carried by said post on said tapered portion and adapted to be operated by gravity to the larger end of said shank and to engage the inner surface of a casing when the members are in one position and adapted to be operated by gravity to the smaller end of said shank out of engagement with said casing when the members are reversed in position, a casing secured to the other of said clamping members and adapted to telescope over said post, substantially as described.

11. In a binder, the combination of a pair of clamping members, a post having a tapered shank portion, a pair of dogs having a serrated surface carried by said post on said tapered portion and adapted to be operated by gravity to the larger end of said shank and to engage the inner surface of a casing when the members are in one position and adapted to be operated by gravity to the smaller end of said shank out of engagement with said casing when the members are reversed in position, a casing secured to the other of said clamping members and adapted to telescope over said post, substantially as described.

809,497. FIRE-RESISTING CABINET. WILLIS V. DICK, Columbus, Ohio. Filed Feb. 7, 1905. Serial No. 244,642.



Claim.—1. In a fire-resisting cabinet, the combination with a base, of end and back walls of sheet metal, said end wall having an inwardly-standing vertical terminal portion 1ª and said back wall having an outwardly-standing vertical terminal, a tie-piece for connecting the said terminals of said end and back walls consisting of a doubly and oppositely grooved piece in which said terminals project, and means for securing said piece to said terminals.

2. In a fire-resisting cabinet, the combination with a base, of end and back walls of sheet metal, a tie-piece and brace for connecting the vertical terminals of said end and back walls and bracing the same, consisting of strip of metal bent to form a double groove into which the said terminals project and a wing to constitute the brace.

3. In a fire-resisting cabinet, the combination with the interior and exterior end walls, said interior end walls being provided with shelf-receiving grooves, of a doubly-grooved strip for connecting the vertical terminals of said walls, said strip being notched to permit the insertion of the shelves into said grooves.

4. In a cabinet, a shelf consisting of a sheet of metal having its outer edge beat and folded to form a bracing-bead, portions of which

extend in opposite directions from said edge and notches in each of the edges of said flange to receive partitions.

5. In a cabinet, a shelf consisting of a sheet of metal having its outer edge bent and folded at said edge to form a bracing-bead for the shelf and notches in said bead to receive partitions.

6. In a cabinet, a shelf consisting of a sheet of metal bent along its rear edge to form a ridge and notches in said ridge to receive partitions.

7. In a cabinet, a shelf consisting of a sheet of metal bent upwardly and downwardly along its rear edge to form ridges at its upper and lower sides, and notches in said ridges to receive partitions.

8. In a cabinet, a shelf consisting of a sheet of metal bent and folded at its outer edge to form a strengthening-bead, notches in said bead to receive the forward portion of the edge of a partition, and said shelf bent along its rear edge to form a ridge or rib and notches in said last-named rib to receive the rear portion of the edge of a partition.

9. In a fire-resisting cabinet, the combination with a suitable base, of the vertical casing thereof comprising an outer wall of sheet metal made in three pieces, to wit, end portions 1 having back portions 1^a integral therewith extending partially across the back, and portions 1^b integral with the end portions extending partially across the front and a portion 2 connecting the edges of the portions 1^a at the back, and an inner wall also of sheet metal extending parallel to the outer wall and joined thereto at or near the edge of the wall 1^b, substantially as described.

809,498. **CONFECTIONER'S SIZING AND CUTTING MACHINE.** GEORGE F. DICKSON, Chicago, Ill., assignor to Confectioners and Bakers Supply Co., a Corporation of Illinois. Filed Dec. 10, 1904. Serial No. 236,286.

Claim.—1. In a sizing and cutting machine for candy and the like, the combination of a supporting-bed, a series of sizing and cutting rolls journaled in parallel relation above said bed in supporting-heads, which in turn are journaled above said bed, means for locking said heads at points in their circular adjustment, and means for feeding the material along said bed, substantially as set forth.

2. In a sizing and cutting machine for candy and the like, the combination of a supporting-frame, a bed secured to said frame, heads or supports journaled in said frame and adapted for a turning adjustment, a sizing-roll and a cutting-roll journaled in parallel relation in said heads, and means for feeding the material along said bed, substantially as set forth.

3. In a sizing and cutting machine for candy and the like, the combination of a supporting-frame, a bed secured to said frame, vertically-adjustable slides on said frame, heads or supports journaled on said slides and adapted for a turning adjustment thereon, a sizing-roll and a cutting-roll journaled in parallel relation on said heads, and means for feeding the material along said bed, substantially as set forth.

4. In a sizing and cutting machine for candy and the like, the combination of a supporting-frame, a bed secured to said frame, heads or supports journaled in said frame and adapted for a turning adjustment, a sizing-roll and a cutting-roll journaled in parallel relation in said heads, and a feed-roll journaled in the main frame beneath the rolls aforesaid, substantially as set forth.

5. In a sizing and cutting machine for candy and the like, the combination of a supporting-bed, a series of sizing and cutting rolls journaled in parallel relation above said bed in supporting-heads, which in turn are journaled above said bed, means for locking said heads at points in their circular adjustment, and means for feeding the material along said bed, substantially as set forth.

6. In a sizing and cutting machine for candy and the like, the combination of a supporting-frame, a bed secured to said frame, heads or supports journaled in said frame and adapted for a turning adjustment, a sizing-roll and a cutting-roll journaled in parallel relation in said heads, means for securing said heads at the required turning adjustment, and means for feeding the material along said bed, substantially as set forth.

7. In a sizing and cutting machine for candy and the like, the combination of a supporting-frame, a bed secured to said frame, vertically-adjustable slides on said frame, heads or supports journaled in said slides and adapted for a turning adjustment thereon, a sizing-roll and a cutting-roll journaled in parallel relation on said heads, means for securing said heads at the required turning adjustment, and means for feeding the material along said bed, substantially as set forth.

8. In a sizing and cutting machine for candy and the like, the combination of a supporting-frame, a bed secured to said frame, heads or supports journaled in said frame and adapted for a turning adjustment, a sizing-roll and a cutting-roll journaled in parallel relation in said heads, means for securing said heads at the required turning adjustment, and a feed-roll journaled in the main frame beneath the rolls aforesaid, substantially as set forth.

9. In a sizing and cutting machine for candy and the like, the combination of a supporting-frame, a bed secured to said frame vertically-adjustable slides on said frame, heads or supports journaled on said slides and adapted for a turning adjustment thereon, a sizing-roll and a cutting-roll journaled in parallel relation on said heads, means for securing said heads at the required turning adjustment, and a feed-roll journaled in the main frame beneath the rolls aforesaid, substantially as set forth.

10. In a sizing and cutting machine for candy and the like, the combination of a supporting-frame, a bed secured to said frame, heads or supports journaled in said frame and adapted for a turning adjustment, a sizing and a cutting roll journaled in parallel relation in said heads, means for securing said heads at the required turning adjustment, the same comprising a disk carried by the journal-shaft of said heads and provided with peripheral notches and a spring latch-bolt on the main frame adapted for engagement with said notches, and means for feeding the material along said bed, substantially as set forth.

11. In a sizing and cutting machine for candy and the like, the combination of a supporting-frame, a bed secured to said frame, vertically-adjustable slides on said frame, heads or supports journaled on said slides and adapted for a turning adjustment thereon, a sizing-roll and a cutting-roll journaled in parallel relation on said heads, means for securing said heads at the required turning adjustment, the same comprising a disk carried by the journal-shaft of said heads and provided with peripheral notches and a spring latch-bolt on the main frame adapted for engagement with said notches, and means for feeding the material along said bed, substantially as set forth.

12. In a sizing and cutting machine for candy and the like, the combination of a supporting-frame, a bed secured to said frame, heads or supports journaled in said frame and adapted for a turning adjustment, a sizing-roll and a cutting-roll journaled in parallel relation in said heads, means for imparting positive rotation to said sizing and cutting rolls, and means for feeding the material along said bed, substantially as set forth.

13. In a sizing and cutting machine for candy and the like, the combination of a supporting-frame, a bed secured to said frame, vertically-adjustable slides on said frame, heads or supports journaled on said slides and adapted for a turning adjustment thereon, a sizing-roll and a cutting-roll journaled in parallel relation on said heads, means for imparting positive rotation to said sizing and cutting rolls, and means for feeding the material along said bed, substantially as set forth.

14. In a sizing and cutting machine for candy and the like, the combination of a supporting-frame, a bed secured to said frame, heads or supports journaled in said frame and adapted for a turning adjustment, a sizing-roll and a cutting-roll journaled in parllael relation on said heads, a feed-roll journaled in the main frame beneath the rolls aforesaid, and means for imparting positive rotation to the sizing, cutting and feed rolls, substantially as set forth.

15. In a sizing and cutting machine for candy and the like, the combination of a supporting-frame, a bed secured to said frame, vertically-adjustable slides on said frame, heads or supports journaled on said slides and adapted for a turning adjustment thereon, a sizing-roll and a cutting-roll journaled in parallel relation on said heads, a

feed-roll journaled in the main frame beneath the rolls aforesaid, and means for imparting positive rotation to the sizing, cutting and feed rolls, substantially as set forth.

16. In a sizing and cutting machine for candy and the like, the combination of a supporting-frame, a bed secured to said frame, heads or supports journaled in said frame and adapted for a turning adjustment, a sizing-roll and a cutting-roll journaled in parallel relation on said heads, the said cutting-roll comprising a series of circular blades secured together in separated relation and a series of clearing-bars loosely arranged between said blades, and means for feeding the material along said bed, substantially as set forth.

17. In a sizing and cutting machine for candy and the like, the combination of a supporting-frame, a bed secured to said frame, vertically-adjustable slides on said frame, heads or supports journaled on said slides and adapted for a turning adjustment thereon, a sizing-roll and a cutting-roll journaled in parallel relation on said heads, said cutting-roll comprising a series of circular blades secured together in separated relation and a series of clearing-bars loosely arranged between said blades, and means for feeding the material along said bed, substantially as set forth.

18. In a sizing and cutting machine for candy and the like, the combination of a supporting-frame, a bed secured to said frame, heads or supports journaled in said frame and adapted for a turning adjustment, a sizing-roll and a cutting-roll journaled in parallel relation on said heads, the said cutting-roll comprising a series of circular blades secured together in separated relation and a series of clearing-bars loosely arranged between said blades, and a feed-roll journaled in the main frame beneath the rolls aforesaid, substantially as set forth.

19. In a sizing and cutting machine for candy and the like, the combination of a supporting-frame, a bed secured to said frame, vertically-adjustable slides on said frame, heads or supports journaled on said slides and adapted for a turning adjustment thereon, a sizing-roll and a cutting-roll journaled in parallel relation on said heads, said cutting-roll comprising a series of circular blades secured together in separated relation and a series of clearing-bars loosely arranged between said blades, and a feed-roll journaled in the main frame beneath the rolls aforesaid, substantially as set forth.

809,499. **TOOL FOR GRINDING GLASS PLATES.** FRIEDERICH FRANS, Corona, N. Y. Filed Jan. 31, 1905. Serial No. 243,496.

Claim.—1. A tool for grinding glass plates, mirrors or the like, comprising a series of blades placed side by side, the thickness of each of said blades and the shape of the upper and lower edges thereof corresponding with the respective line to be ground, said upper and lower edges serving as the cutting edges of the tool, the vertical side edges of each blade being sloped rearward and outward rendering the front surface narrower than the rear surface thereof, and means for fastening the blades to each other after adjustment, substantially and for the purpose as specified.

2. A tool for grinding glass plates, mirrors or the like, comprising a series of blades placed side by side, the thickness of each of said blades and the shape of the upper and lower edges thereof corresponding with the respective line to be ground, said upper and lower edges serving as the cutting edges of the tool, one of the vertical side edges of each blade being sloped rearward and outward and the other being cut so as to conform with a portion of any figure desired to represent a setting, and means for fastening the blades to each other after adjustment, substantially and for the purpose as specified.

809,500. **WINDOW-VENTILATOR.** GEORGE W. FROELICH, Chicago, Ill. Filed Jan. 23, 1905. Serial No. 242,227.

Claim.—1. In a window-ventilator, the combination with an outer frame, of plates on the sides of said frame, each provided at its upper end with a horizontal groove or hinge-socket, an inner frame, and hinge-sections upon the rear surface and at the sides thereof adapted to ride in said sockets.

2. In a window-ventilator, the combination with an outer frame, of plates mounted on the rear walls of said frame, each provided at its upper end with a horizontal groove or socket, an inner frame, hinge-plates upon the rear surface and near the edges of said frame, each plate carrying at its lower end a cylindrical portion adapted to ride in one of said sockets, and stops carried by the outer frame adapted to limit the movement of said inner frame.

3. In a window-ventilator, the combination with an outer metal frame, of plates mounted on the rear walls of said frame, each provided at its upper end with a horizontal groove or socket, an inner metal frame, a hinge-plate upon the rear surface and at each side of said frame carrying at its lower end a cylindrical portion adapted to ride in one of said grooves, and inwardly-turned flanges at the top and bottom of said outer frame, extending on opposite sides of the inner frame to serve as stops therefor.

4. In a window-ventilator, the combination with an outer metal frame composed of two U-shaped sections united at their ends by couplers, each coupler comprising two vertical plates, united by a web extending between opposite sides of said plates, the upper end of the lower plate having a horizontal groove therein, and an inner frame carrying upon its rear surface and at its sides plates having enlarged and rounded lower ends seated in said horizontal grooves.

5. In a window-ventilator, the combination with an outer frame consisting of two U-shaped members formed of angle-iron arranged to bring two flanges in opposition to form front and rear jambs, the remaining flanges forming top, bottom and sides of the frame, hinge-sections connecting said U-shaped members and having webs lying flush with the sides of said outer frame and abutting end to end therewith, said sections having front and rear extensions overlapping the front and rear jambs and provided with shoulders receiving the ends thereof, the lower extensions having horizontal grooves in their upper ends, an inner frame formed of angle-iron, hinge-sections for said frame having hinge portions seated in said grooves and forming the swinging axes of said inner frame, and stops engaging the upper and lower ends of said inner frame on opposite sides thereof.

809,501. **ANTIVIBRATION DEVICE FOR VEHICLES.** GEORGES GRILLIER, Chicago, Ill., assignor to The Automobile Importing Company, Chicago, Ill., a Corporation. Filed Apr. 26, 1905. Serial No. 257,495.

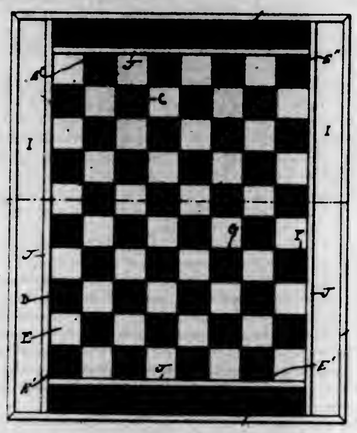
Claim.—1. An antivibration device for vehicles, comprising two arms pivoted together and having respectively a casing and a friction-ring in contact therebetween, the pivot-bolt connecting the arms having a tapered sleeve-nut which fits in a tapered socket in one of the arms.

2. An antivibration device for vehicles, comprising two arms pivoted together, one arm having a circular casing around the pivot, and the other arm having a split ring within the casing and in continuous frictional contact therewith, and means to expand or contract the ring to vary the friction.

3. An antivibration device for vehicles, comprising two arms pivoted together, one arm having a cylindrical casing around the pivot and the other arm carrying a split ring within the casing and in frictional contact therewith, and a tapered bolt between the split ends of the ring, adjustable to expand or contract the ring.

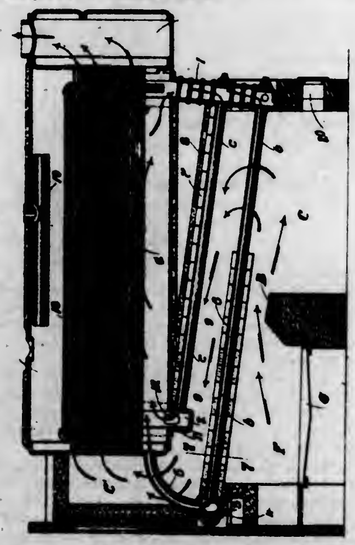
4. An antivibration device for vehicles, comprising two arms pivoted together, one arm having a cylindrical casing around the pivot and the other arm having a cap-plate covering the end of the cylinder, a split ring secured to the cap-plate, and a tapered bolt secured to the plate and located between the ends of the split ring.

809,502. GAME-BOARD. NELSON T. HALE, Baldwinville, Mass.; Ashley G. Hale administrator of said Nelson T. Hale, deceased. Filed July 7, 1903. Serial No. 164,885.



Claim.—In a game apparatus, a board having a checkered surface, having rectangular spaces on each side and rectangular spaces on each end interposed between the spaces on the side, said end spaces being of different identity, each of the transverse rows of the checkered surface having playing-surfaces of equal number, the outer row at each end having identities differing from each other and the remaining rows, and a series of playing-pieces comprising two sets uniform as to marking, certain of said pieces carrying a valuation, and certain of said pieces having no valuation but acting as checks, said sets being of different identities but each set corresponding with an identity of one of the outer transverse rows of the checkered surface, and the identity of one of the rectangular end spaces.

809,503. STEAM-BOILER. CHARLES W. HAWKES, Chicago, Ill. Filed Aug. 21, 1905. Serial No. 275,043.



Claim.—1. A boiler comprising a series of superposed water-tube sections, a fire-tube section surmounting the same, a water-leg connecting one end of the respective water-tube sections with the adjacent end of the fire-tube section, and independent means for connecting the opposite ends of the respective water-tube sections with the fire-tube section, the space between the water-tube sections communicating with the fire-tube section at the end adjacent to said water-leg, substantially as set forth.

2. A boiler comprising a series of superposed water-tube sections, a fire-tube section surmounting the same, a water-leg connecting one end of the respective water-tube sections with the adjacent end of the fire-tube section, a smoke box or flue leading from the fire-tube section at the end adjacent to said water-leg, and independent means for connecting the opposite ends of the respective water-tube sections with the adjacent end of the fire-tube section, the space between the water-tube sections communicating with the fire-tube section at the end opposite the smoke-box, substantially as set forth.

3. A boiler comprising two superposed water-tube sections, the front end of the lower section being extended forwardly beyond that of the upper section, a fire-tube section surmounting the aforesaid water-tube sections, a water-leg depending from the rear end of the shell of the fire-tube section and establishing communication between said shell and the rear ends of the water-tube sections, a water-saddle communicating with the front end of the shell of the fire-tube section and with the front end of the upper water-tube section, a header communicating with the front end of the lower water-tube section, and a series of circulating-pipes establishing communication between said header and the shell and saddle of the fire-tube section respectively, substantially as set forth.

4. A boiler comprising two superposed water-tube sections, a fire-tube section surmounting the same, a water-leg depending from the rear end of the fire-tube section and establishing communication between said section and the adjacent ends of the water-tube sections, a water-saddle establishing communication between the front of the fire-tube section and the upper water-tube section, a header into which the front end of the lower water-tube section leads, circulating-tubes establishing communication between the header and the saddle and the front of the fire-tube section respectively, a partition-wall formed in connection with the lower water-tube section and extending a suitable distance rearwardly, a partition-wall formed in connection with the upper water-tube section for substantially the full length of the latter, and a smoke box or flue leading from the rear of the fire-tube section, substantially as set forth.

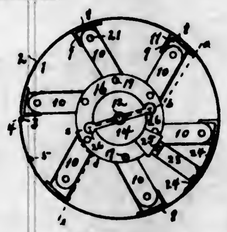
5. In a boiler, an upper fire-tube section, a lower water-tube section, an intermediate water-tube section, a rear water-leg depending from the fire-tube section and establishing communication with the rear ends of the water-tube sections, the latter being disposed in substantially parallel planes and inclining forward and upward toward the fire-tube section, a front water-saddle establishing communication between the fire-tube section and the intermediate or upper water-tube section, the lower water-tube section extending forwardly beyond the front of the fire-tube section, a header at the front upper end of the lower water-tube section, and a series of circulating-pipes connecting the header with the fire-tube section and tapping the latter at a point or plane above the upper end of the intermediate or upper water-tube section, substantially as set forth.

6. In combination with a boiler-furnace having a fire-box and bridge-wall, a boiler comprising a lower water-tube section, an upper water-tube section, a fire-tube section surmounting the aforesaid sections, means for establishing communication between the several sections, a partition-wall formed in connection with the lower water-tube section and extending a suitable distance rearwardly beyond the bridge-wall, a partition formed in connection with the upper water-tube section whereby a conduit is formed between said partitions for the passage of the combustion products, said conduit communicating with one end of the fire-tube section, substantially as set forth.

7. In a boiler, an upper fire-tube section, a lower water-tube section, an intermediate or upper water-tube section spaced therefrom and forming a conduit therewith, a smoke-box at the rear end of the fire-tube section, means for directing the combustion products rearwardly along the base of the lower water-tube section, thence forwardly through said conduit into the front end of the fire-tube section, thence rearwardly through the fire-tube section into the smoke-box, substantially as set forth.

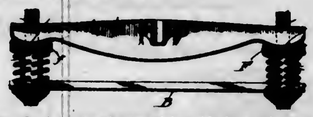
809,504. MOLD-FORMING MECHANISM. GEORGE HEHNEGREN, Kimballton, Iowa, assignor to Henningsen & Jensen, a Firm. Filed Sept. 26, 1905. Serial No. 280,444.

Claim.—1. Mold-forming mechanism, in combination, comprising an inner mold 6 and an outer mold 27; said inner mold having a central rotatable shaft 12, and rigidly-mounted brackets 7 mounted upon the inner wall 1 of said mold; the plate 16 rigidly mounted upon said shaft; the links 10 pivotally mounted upon said brackets 7 and upon said plate 16; the flanges 3 and 4 adapted to make engagement one with the other; the clasp 23 adapted to make engagement with eyes 24; the handles 26; the cover 33; the rim-molds 31 and 35; said outer mold having the flanges 28 and 29 and clasps 30 substantially as shown and described.



2. Mold-forming mechanism, in combination, comprising an inner mold 6 and an outer mold 27; said inner mold having a central rotatable shaft 12, and rigidly-mounted brackets 7 mounted upon the inner wall 1 of said mold; said brackets being formed of integral and substantially rectangular sheets of metal incised substantially upon the lines *f g* to form leaves 11 adapted to be used as pivotal bearings for said rods 22; the plate 16 rigidly mounted upon said shaft; the links 10 pivotally mounted upon leaves 11 of brackets 7, the opposite end of said links being pivotally mounted upon said plate 16; the flanges 3 and 4 adapted to make engagement one with the other; the flange 5 adapted to make engagement with flange 3; the clasp 23 adapted to make engagement with eyes 24; the handles 26; the cover 33; said rim-mold 31 having the slot 32 said outer mold having the flanges 28 and 29 and clasps 30, substantially as shown and described.

809,505. CAR-TRUCK. JAMES M. HOPKINS, Chicago, Ill. Filed June 5, 1905. Serial No. 263,709.



Claim.—1. A car-truck comprising side frames having openings therein, spring-caps within the upper portion of said openings and a bolster having its ends engaging said spring-caps, said spring-caps and said bolster being interlocked by ball-and-socket joints covering substantially the entire top surfaces of said spring-caps and permitting a rocking movement of the bolster upon the spring-caps in a direction transverse to the length of the bolster.

2. A car-truck comprising side frames having openings therein, a spring-plank having its ends within said side openings, springs upon said spring-plank, spring-caps for said springs and a bolster projecting through said side-frame openings, said bolster and said spring-caps being connected by ball-and-socket joints covering substantially the entire top surfaces of said spring-caps and permitting a rocking movement of the bolster upon the spring-caps in a direction transverse of the bolster.

3. A car-truck comprising side frames having openings therein, a spring-plank having its ends within said opening, springs upon said spring-plank, spring-caps for said springs provided with sockets covering substantially the entire top surface of said spring-caps, and a bolster having its ends provided with transversely-curved offsets to enter the correspondingly-curved sockets of said spring-caps.

809,506. SAFETY-MATCH BOX. JULIUS KARPEN, Chicago, Ill. Filed Feb. 1, 1904. Serial No. 191,286.

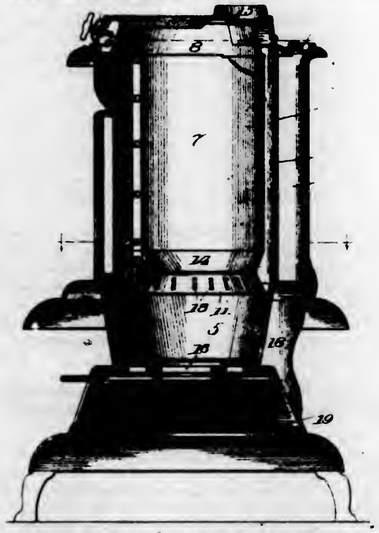
Claim.—1. A commercial box of matches, said box comprising the usual slide and cover, provided with a plurality of removable striking-panels arranged along one side thereof, and conforming to the size and contour of said side.

2. A commercial box of matches, said box comprising the usual slide and cover, provided with a plurality of removable striking-panels arranged along one side thereof, said panels being formed of a continuous folded blank provided with tear lines or divisions, whereby said panels when folded will conform to the size and contour of the side of said box.

3. A commercial box of matches, said box comprising the usual slide and cover, provided with a plurality of removable striking-panels arranged along one side thereof, said panels being formed of a continuous folded blank having scalloped edges and tear lines or divisions intersecting said edges and coincident with the scallops, whereby said panels when folded will conform to the size and contour of the side of said box.

4. A commercial box of matches provided with a plurality of striking-panels arranged exteriorly along one edge thereof and conforming to the size and contour of said side, and a binder embracing said panels and said box.

809,507. HEATER. JULIUS L. KLEBER, Quincy, Ill. Filed Aug. 1, 1904. Serial No. 219,071.



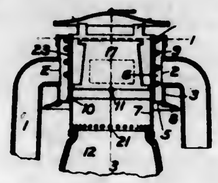
Claim.—1. In a heater of the character described, the combination of a drum, a combustion-chamber, a heating-chamber above the combustion-chamber, a dome above the heating-chamber, an annular air-receiving chamber located in the dome adjacent to its outer wall and having its inlet-opening at the front of the heater, an air-distributing ring in the combustion-chamber, a vertical ventiduct within the heating-chamber at the back thereof and connecting the receiving-chamber and the distributing-ring, and a hot-air chamber outside of the drum behind the ventiduct, a part of the drum forming a wall for both the hot-air chamber and the ventiduct.

2. In a heater of the character described, the combination of a drum, a combustion-chamber, a heating-chamber above the combustion-chamber, a dome, an annular air-receiving chamber located in the dome adjacent to its outer wall and having its inlet-opening at the front of the heater, a hollow air-distributing ring in the combustion-chamber and having an inwardly and upwardly inclined wall provided with openings through which the air is discharged downwardly in the combustion-chamber, a vertical ventiduct within the heating-chamber at the back thereof and connected at one end to the back of the receiving-chamber and at its other end to the back of the distributing-ring, and a hot-air chamber outside of the drum, a part of the drum forming a wall for both the hot-air chamber and the ventiduct.

809,508. LANTERN. DAVID C. KLINE, Rochester, N. Y., assignor to Albert R. Pritchard, Thomas B. Pritchard, and Henry A. Strong, all of Rochester, N. Y., The Firm of Pritchard Manufacturing Company. Filed Dec. 9, 1904. Serial No. 236,165.

Claim.—1. In a tubular lantern, a globe-holder tube having opposite perforations through its side, and deflector-plates each fastened by one edge inside said tube and opposite the said perforations and gradually diverging from the inner side of the globe-tube whereby air may pass around all the edges of the deflector-plate except the edge by which it is fastened to the globe-holder tube, an outer tube

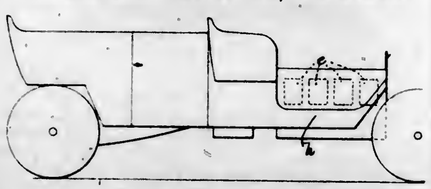
around the globe-holder tube, having opposite perforations connecting with the side tubes, the side tube perforations and the perforations through the globe-holder tube being substantially at right angles to each other.



2. In a tubular lantern, a globe-holder tube having opposite perforations through its sides and one or more vertical ribs, deflector-plates each fastened by one edge inside said tube opposite one of said perforations and gradually diverging from the inner side of the globe-holder tube, whereby air may pass around all the edges of the deflector-plate except the edge by which it is fastened to the globe-holder tube, an outer tube around the globe-holder tube having opposite perforations connecting with the air-tubes, the air-tube perforations and the perforations through the globe-holder tube being substantially at right angles to each other, one or more guides for said ribs in said outer tube, and spring means for holding the two tubes in position.

3. In a tubular lantern, air-tubes, an outer tube having opposite perforations through its sides connecting with the air-tubes, a globe-holder tube inside the outer tube having opposite perforations through its sides out of line with the perforations in the outer tube, and a deflector-plate opposite each perforation in the globe-holder tube and fastened at one edge inside said globe-holder tube and open to the interior of said globe-holder tube around its remaining edges.

809,509. **MOTOR-CAR.** FREDERICK W. LANCHESTER, Edgbaston, Birmingham, England. Filed June 3, 1905. Serial No. 263,579.



Claim.—1. A motor-vehicle in which the motor is situated in the leg-space of the front seat and in proximity to the dashboard of the vehicle, substantially as and for the purposes set forth.

2. A motor-vehicle in which the motor is situated in the leg-space forward of the front seat of the vehicle and to the rear of the dashboard, the motor equally dividing said space longitudinally, substantially as and for the purposes set forth.

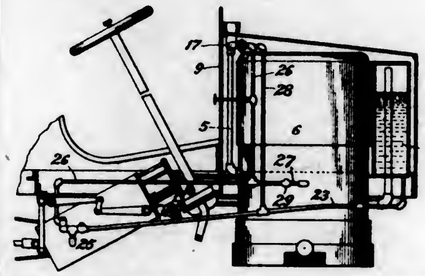
3. A motor-vehicle having the motor situated in the leg-space forward of the front seat of the vehicle and to the rear of the dashboard; the motor dividing the leg-space longitudinally and its center of weight being considerably to the rear of the centers of the front wheels, a rear seat and a side entrance for said seat, substantially as described.

4. A motor-vehicle having a chassis-frame consisting of a transverse tubular member and a plurality of longitudinal members secured thereto, some of the members which are nearest the longitudinal center of the car extending forward and supporting the motor while others more remote from said center extend to the rear, substantially as described.

5. A motor-vehicle having a chassis-frame consisting of a transverse tank to which are secured four longitudinal members the inner two of said members being extended forward to support the engine while the outer two extend rearward, substantially as described.

6. A motor-vehicle having a chassis-frame consisting of a transverse tank to which are secured four longitudinal members the inner two of said members being extended forward to carry the fore suspension while the other two members extend rearward to carry the rear suspension, a front seat on said tank and a motor carried on the forward members, said motor dividing the front leg-space longitudinally, substantially as described.

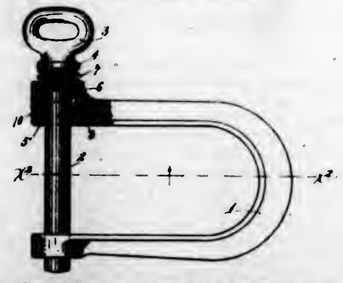
809,510. **WATER-LEVEL REGULATOR.** WILLIAM J. LANE and ORRIN LANE, Poughkeepsie, N. Y. Filed Feb. 15, 1905. Serial No. 245,701.



Claim.—1. An automatic water-level regulator for a steam-boiler comprising a pipe connected at one end to the normal water-level of the boiler, a pipe connected to said first-named pipe, a frame in which said second-named pipe is located and in which it is secured at one end, a lever pivoted in the frame, an adjustable connection between said lever and said second-named pipe, and a valve in the water-supply connections to be actuated by the movement of said lever.

2. An automatic water-level regulator for a steam-boiler comprising a pipe connected at one end to the normal water-level of the boiler, an expansible body connected to said pipe, a lever mounted independent of said expansible body and in operative relation thereto, means for adjusting the lever relatively to said expansible body, a spring-opened valve adapted to be closed by the movement of the lever, and adjustable means for regulating the movement of the valve.

809,511. **INTERLOCKING CLEVIS.** NILS M. LIEN, Langhei, Minn. Filed Sept. 11, 1905. Serial No. 277,974.



Claim.—The combination with an integrally-formed yoke 1, of a pin 2 fitting seats in the prongs thereof, one prong of said yoke having a longitudinal groove 8, lock-notch 10 and countersunk segmental groove 9 connecting said groove 8 and lock-notch 10, and said pin 2 having a single projecting lock-lug 5 adapted to be passed through said grooves 8 and 9 and to be seated in said lock-notch 10, and a coiled spring surrounding said pin 2, reacting against the yoke of said pin and normally holding said lock-lug 5 engaged with said lock-notch 10, substantially as described.

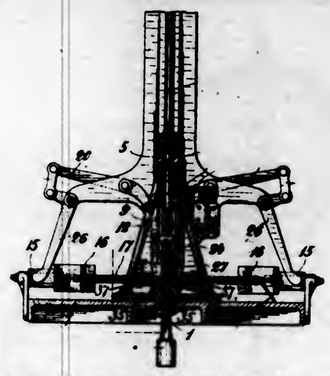
809,512. **MACHINE FOR CUTTING AND PRESSING CANISTERS, &c.** RICHARD VON DER LINDE, Crefeld, Germany. Filed May 20, 1903. Serial No. 161,314.

Claim.—1. A machine for cutting and flattening sheet-metal cans, provided with a knife for cutting the can, and with a movable pressure-plate for flattening the cut can, substantially as specified.

2. A machine for cutting and flattening sheet-metal cans, provided with a divided knife for cutting a can, and with means for flattening the cut can, substantially as specified.

3. A machine for cutting and flattening sheet-metal cans, provided with a divided knife for cutting a can, and with a pair of hinged pressure-plates adapted to flatten the cut can, substantially as specified.

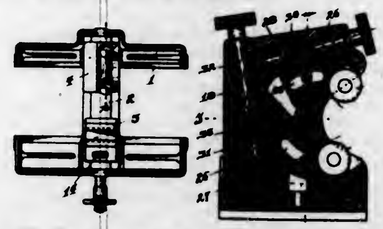
4. A machine for cutting and flattening sheet-metal cans, provided with a divided knife, a pair of vertically-movable hinged pressure-plates, and means for spreading said plates, substantially as specified.



5. A machine for cutting and flattening sheet-metal cans, provided with a pair of reciprocating grippers adapted to center a can, a knife for cutting the can, and a pair of hinged pressure-plates adapted to flatten the cut can, substantially as specified.

6. A machine for cutting and flattening sheet-metal cans, provided with a pair of reciprocating grippers adapted to center a can, a knife for cutting the can, a pair of hinged pressure-plates adapted to flatten the cut can, and a finger pivoted to one of the grippers and adapted to engage the flattened can, substantially as specified.

809,513. **FOLLOWER-REST FOR LATHES.** WILLIAM LODGE and NICHOLAS D. CHARD, Cincinnati, Ohio, assignors to the Lodge & Shipley Machine Tool Company, Cincinnati, Ohio, a Corporation. Filed June 26, 1905. Serial No. 267,063.

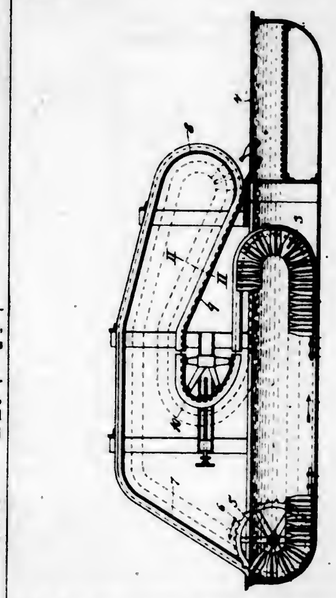


Claim.—1. In a machine of the class described, a carriage, a follower-rest having a guideway connection with the carriage, means for reciprocating the follower-rest on the carriage, said follower-rest consisting of a stock having a curved way formed in its side, segments supported in said way, the exposed ends of the segments forming jaws adapted to engage the periphery of the work in the rear of the tool, and means for adjusting and clamping said segments into said way, substantially as described.

2. In a machine of the class described, a carriage attachment consisting of a stock formed with a curved way, segments adjustably clamped in said way, the front ends of said segments being provided with antifriction-bearings constituting jaws adapted to form a lateral bearing engagement with the periphery of the work in the rear of the tool, substantially as described.

809,514. **BOTTLE-WASHING MACHINE.** CHARLES H. LOEW and HENRY G. MILLER, Cleveland, Ohio, assignors to The Loew Supply & Manufacturing Company, Cleveland, Ohio, a Corporation of New Jersey. Filed Nov. 20, 1903. Serial No. 182,106.

Claim.—1. In a bottle-washing machine, the combination of a soaking-tank, an endless and flexible traveling bottle-conveyer formed with bottle-racks arranged transversely to said conveyer and formed with large openings at their outer sides for the passage of the bottle-bodies and with smaller registering openings at their inner sides for the passage of the bottle-necks and for support of the bottle-breasts, guides and supports for guiding the conveyer through the tank with the bottle-necks pointing in an upward direction, guides and supports for the conveyer to present its large openings outward to receive the bottles to be soaked before entering the tank, guides and supports for the conveyer arranged above the tank to invert the racks to present the bottle-necks toward the tank to discharge their contents as they leave the tank, and guides and supports arranged outside of the tank to present the bottle-racks inclined with their large openings outward to discharge the empty bottles.



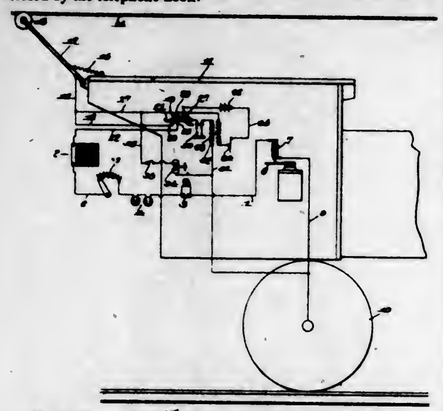
2. In a bottle-washing machine, the combination of a soaking-tank, an endless and flexible traveling bottle-conveyer formed with bottle-racks arranged transversely to said conveyer and formed with large openings at their outer sides for the passage of the bottle-bodies and with smaller registering openings at their inner sides for the passage of the bottle-necks and for support of the bottle-breasts, guides and supports for guiding the conveyer through the tank with the bottle-necks pointing in an upward direction, guides and supports for the conveyer to present its large openings outward to receive the bottles to be soaked before entering the tank, guides and supports for the conveyer arranged above the tank to invert the racks to present the bottle-necks toward the tank to discharge their contents as they leave the tank, and guides and supports arranged outside of the tank to present the bottle-racks inclined with their large openings outward to discharge the empty bottles, and means for spreading said bottles substantially as specified.

3. In a bottle-washing machine, the combination of a soaking-tank, an endless traveling bottle-conveyer consisting of two endless chains and transverse bottle-racks secured at their ends to the chains and formed with bottle-pockets having large outer openings for the passage of the bottle-bodies and small inner openings for the passage of the bottle-necks and support of the bottle-breasts, guides and supports in the tank for the conveyer-chains to conduct the same through the tank with the small openings of the racks pointing in an upward direction, guides and supports for the conveyer and arranged to present the large openings of the pockets for the reception of the bottles to be soaked before entering the tank, guides and supports for the conveyer for presenting the small openings of the bottle-pockets toward the tank as the conveyer leaves the same, guides and supports for the conveyer for presenting the bottle-pockets inclined and with their large openings presenting outward to discharge the empty bottles, and means opposed to the large openings of the bottle-pockets to retain the bottles in the same when said openings are pointing downward.

809,515. **ELECTRICAL RAILWAY SIGNALING SYSTEM.** MILTON H. LOUDON, Kansas City, Mo. Filed June 20, 1905. Serial No. 265,893.

Claim.—1. An electrical railway signaling system embodying a normally closed main circuit including a source of electrical energy,

a rheostat and a solenoid-magnet operatively connected with the engineer's brake-valve, and a normally open local circuit including a telephone and a Morse sounder, the two circuits being opened or closed by the telephone-hook.



2. An electrical railway signaling system embodying a normally closed main circuit including a source of electrical energy, a rheostat, visual and audible signaling mechanism, and a solenoid-magnet operatively connected with the engineer's brake-valve, and a normally open local circuit including a telephone and a Morse sounder, and means actuated by the telephone-receiver either to open or to close the two circuits.

3. In an electrical railway signaling system, a normally closed main circuit including a source of electrical energy, a rheostat, and an electrically-actuated element operatively connected with the engineer's brake-valve, and a normally open circuit including a Morse sounder and a telephone, the opening and closing of the two circuits being controlled by the telephone-hook.

4. In an electrical railway signaling system, a normally closed main circuit including visual and audible signaling mechanism, and a solenoid-magnet combined with the engineer's brake-valve, and a normally open local circuit including a telephone.

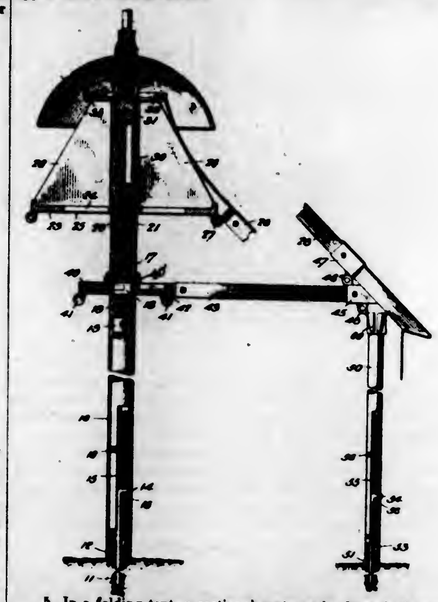
809,516. **TENT.** EDGAR B. MANN, Waterbury, Conn., assignor to Adelaide B. Mann, Waterbury, Conn. Filed Mar. 23, 1905. Serial No. 251,694.

Claim.—1. A foldable tent having a sectional center post, the lower section of which is attached to and forms a support for the upper section during the erecting and striking of the tent, and is detachable to leave a clear space below the upper section when the tent is in use, corner-posts, rafters connecting the corner-posts to the upper end of said upper section, a slide movable on said upper section, and stretcher members extending between the rafters and the slide.

2. A foldable tent having a center piece formed of upper and lower detachable sections, the lower section constituting a support for the upper section during the erecting and striking of the tent, and being detachable to leave a clear space below the upper section when the tent is in use, corner-posts, rafter members extending between the upper end of the upper section and the corner-posts, a slide movable on said upper section, stretcher members extending between the outer ends of the rafters and the slide, and means for locking said slide to the lower portion of said upper section.

3. A folding-tent frame, including a center post formed of upper and lower detachable sections, the lower section serving to support the upper section during erecting and striking, and being detachable to leave a clear space under the upper section when the tent is in use, corner-posts, rafters or stretchers pivotally connected to the corner-posts, the rafters having a pivotal connection with the upper end of the upper section of said center post, and the stretchers forming a truss and supporting the upper section of the center post.

4. In a folding-tent frame, a sectional center post, of which the lower section forms a support for the upper during erecting and striking of the tent, and is detachable to afford a clear space below the upper section when the tent is in use, said upper section being non-circular in form, a slide having a non-circular opening mounted on said upper section, a head-plate secured to the upper section, corner-posts, stretchers extending between the slide and the corner-posts, and rafters pivotally connected to the head-plate and to the upper ends of the stretchers.



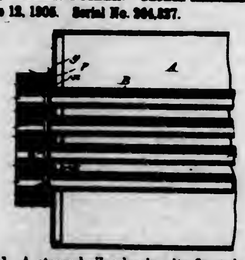
5. In a folding tent, a sectional center pole, formed of metal tubing, a head-plate carried by the pole and provided with a plurality of air-escape openings, a top plate also carried by the pole and provided with similar openings, said top plate being provided with a peripheral groove to receive the top of the tent fabric, vertical partitions extending between the head-plate and top plate, and forming channels for the passage of air, and a protecting-hood carried by the pole and extending over the top plate.

6. In tents, a hollow post, open at its lower end and provided with a slotted wall, and a ground-pin arranged within the post and having a driving-head extending through the slot

7. A tent-post formed of a tube open at its lower end and provided with a slotted wall, there being recesses formed in the walls of the slot, a driving-pin arranged in the post and having an arm projecting through the slot to form a driving-head, said arm being insertible in any one of the recesses to lock the post to the ground.

8. In a tent-post, a hollow tube having at its lower end a ferrule provided with a tapered opening and having a vertical slot, the edges of which are recessed, and a ground-pin arranged within the tube and having an arm projecting through the slot and forming a driving-head.

809,517. **STEAM-BOILER.** GEORGE MARSHALL, Fremont, Nebr. Filed June 12, 1905. Serial No. 264,837.



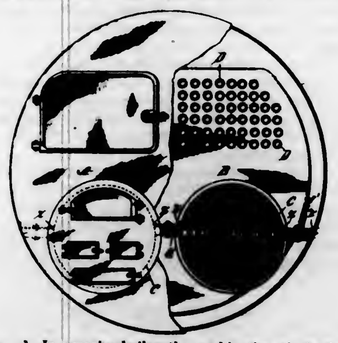
Claim.—1. A steam-boiler having its fire-tubes projecting beyond the tube-sheet and beaded as described, and a metallic protecting-plate resting in close contact with the tube-sheet, and having holes registering with the tubes, the walls of the holes being formed to closely surround the beaded ends of the tubes, being flared or inclined outwardly and inclined or curved inwardly by being calked around the beaded ends of the tubes to tightly fit them.

2. The combination of a tube-sheet, fire-tubes projecting therethrough and beaded as described, a protecting-plate secured to the tube-sheet, being in close contact therewith and having holes registering with the tubes, the walls of the said holes being formed to fit the beaded ends of the tubes and being calked thereto to make a tight joint, and a protecting-wall made in separable flanged sections, applied to the plate and completely covering its front face and its four edges.

3. The combination of the boiler-head, the fire-tubes, the protecting-plate secured to the boiler-head, the metal frame-pieces attached to the plate and the sectional protecting-wall connected with the frame-pieces.

4. The combination of the fire-tubes, the boiler-head, the protecting-plate attached thereto, the frame-pieces attached to the plate and the protecting-wall having interlocking connections with the frame-pieces and recesses to expose the fastening devices of the frame-pieces, and the wall-sections for filling said recesses.

809,518. **MARINE BOILER.** GEORGE MARSHALL, Fremont, Nebr. Filed Sept. 11, 1905. Serial No. 277,978.



Claim.—1. In a marine boiler, the combination of a horizontal furnace flue or casing, a boiler-shell surrounding it, and partitions fitting the boiler-shell and the furnace flue or casing which separate the water in the lower portion of the boiler from that in the upper portion.

2. In a marine boiler, the combination of a horizontal furnace flue or casing, a boiler-shell surrounding it, and a partition fitting the boiler-shell, and calked to the furnace flue or casing which separates the water in the lower portion of the boiler from that above it.

3. The combination in a marine boiler of the boiler-shell, the flue and a partition for separating the water in the lower portion of the boiler from that in the upper portion which comprises a body portion and a metal plate secured thereto which is calked to the flue and shell.

4. A marine boiler comprising a shell, and a plurality of horizontal furnace flues or casings, and partitions separating the water in the lower portion of the boiler from that in the upper portion arranged between the furnace flues or casings and the shell and between adjacent flues.

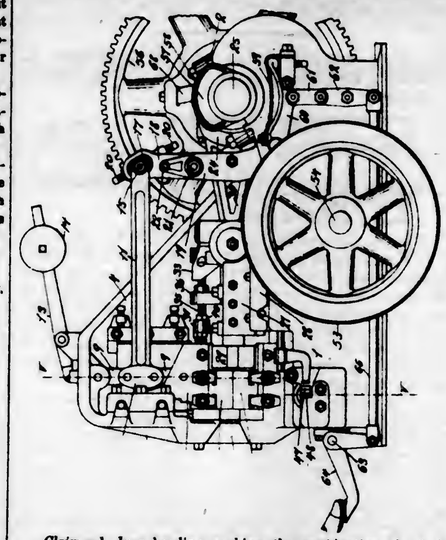
5. The combination with a marine boiler having an inclosing shell and a corrugated furnace-flue, of a partition for separating the water in the lower portion of the boiler from that in the upper portion, comprising a cast-metal bar corrugated to conform to the corrugations of the flue and a metal plate attached thereto which is also corrugated and closely fits the flue and the boiler-shell.

809,519. **METALLIC HOOP.** GEORGE L. MEADE, Cleveland, Ohio. Filed June 7, 1905. Serial No. 264,113.

Claim.—1 A metallic hoop having beads at the edges formed by curling the metal, and lapped ends one of which fits at its edges under the beads on the other end.

2. A metallic hoop comprising a strap having beads at the edges which meet at the ends, one end being narrowed and fitting at its edges under the beads on the other end.

809,520. **HEADING-MACHINE.** REMUS C. MEYER, Cleveland, Ohio, assignor to The Champion Machinery Company, Cleveland, Ohio, a Corporation of Ohio. Filed Jan. 2, 1904. Serial No. 187,404.



Claim.—1. In a heading-machine, the combination of a bed-frame having an overhanging upright front forming a feed-opening open at three sides, a stationary clamping-die supported in the bottom of said feed-opening with its die-face in a horizontal plane, a vertically-movable clamping-die guided in the overhanging front of the frame to act against the stationary die and having means for moving it, and a heading slide and die having means for reciprocating it and guided to slide in the plane of the die-face of the stationary clamping-die.

2. In a heading-machine, the combination of a bed-frame having a horizontal guide and an upright frame portion at its front formed with a vertical guide and a feed-opening beneath said guide and open at three sides, a heading-slide and die in the horizontal guide, means for reciprocating such slide, a stationary clamping-die horizontally supported to have its upwardly-facing die-face in the plane of motion of the heading-die and beneath the vertical guide of the upright front portion of the frame, a movable clamping-die having its downwardly-facing die-face opposed to the face of the stationary die and vertically movable in the guide in the upright front portion toward and from the stationary die, and means for reciprocating said movable die.

3. In a heading-machine, the combination with a clamping slide and die guided to reciprocate, an arm connected to said slide to reciprocate the same, and a rock-arm having means for rocking it, of an arm pivoted to said rock-arm and having the slide-operating arm pivoted to its end, and a break-pin inserted through the rock-arm and the pivoted arm to normally keep the latter rigid to the former and to part when subjected to undue strain.

4. In a heading-machine, the combination with a clamping slide and die guided to reciprocate, an arm connected to said slide to reciprocate the same, two rock-arms, and means actuating said rock-arms, of an arm pivoted between said rock-arms and having the slide-operating arm pivoted to it, and a break-pin inserted through the arm and the rock-arms.

5. In a heading-machine, the combination with a heading-slide guided to reciprocate, a clamping slide and die guided to reciprocate, toggles connected to said slide, and an arm pivoted to said toggle to flex and straighten the same, of forked rock-arms having said toggle-arm pivotally connected to them and having rollers in their branches, a main shaft having means for rotating it and having a crank the cheeks of which are straddled by the forked rock-arms and are formed into cams against which the rollers bear, and a pitman connected to the crank and to the heading-die.

6. In a heading-machine, the combination with a pair of clamping-dies and a reciprocating heading slide and die, of a shaft journaled to rock parallel with said slide and provided with an adjust-

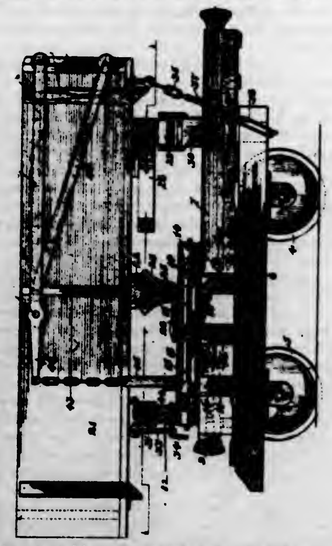
able gage at one end to swing into the path of the heading-die when the latter recedes and with a radial arm, and a web upon the heading-die and formed with an inclined groove engaging the radial arm and rocking the shaft as the slide is reciprocated.

809,521. **INK-DISTRIBUTER FOR PRINTING-PRESSES.** JOSEPH S. MCKINLEY, Cincinnati, Ohio. Filed June 7, 1905. Serial No. 264,080.

Claim.—1. In a machine of the class described, a bed, an ink-distributing sleeve-roll, a main inking-roll contacting the same, a worm-rod passing through the sleeve, a thread-engager carried by the sleeve, means for holding said rod stationary, consisting of an upright rod secured at its lower end to the bed and projecting above the same, a horizontal rod extended toward the bed, a vertically-depending rod to the lower end of which the worm-rod is secured, and adjustable connections between said rods adapted to make adjustments in various planes, substantially as described.

2. In a machine of the class described, an inking-roll, a contacting ink-distributing sleeve-roll, a rod having a single worm-thread at one end with devices at each end of the thread for reversing the thread-engager, means for holding said rod rigidly within said sleeve, a thread-engager swiveled in the end of the sleeve and having a spring-controlled engagement with the worm, and a bearing-bushing secured to the sleeve within the same engaging the rod and adapted to rotate thereon while being reciprocated on the rod by the worm-driving mechanism, substantially as described.

809,522. **DUMP-CAR.** THOMAS R. MCKNIGHT, Aurora, Ill., assignor to Western Wheeled Scraper Company, Aurora, Ill., a Corporation of Illinois. Filed July 11, 1903. Serial No. 165,118.



Claim.—1. A dump-car, consisting of a wheeled truck, a tilting car-body having an open end, an edgewise-movable gate therefor, a rotary support on which said car-body rests, and means rotating with the car-body for automatically holding up the end gate when the car-body is tilted to dump the load.

2. A dump-car, consisting of a wheeled truck, a car-body having an open end, an end gate therefor pivotally connected with the car-body, and means for securing said end gate out of operative position to expose the open end of the car-body when the car-body is in its normal position, substantially as described.

3. A dump-car, consisting of a wheeled truck, a car-body having an open end, an end gate therefor, a pivoted lever connecting said end gate with the car-body, and means for securing said end gate up out of operative position when the car-body is in its normal position to expose the open end of the car-body, substantially as described.

4. A dump-car, consisting of a wheeled truck, a tilting car-body open at one end, an edgewise-movable end gate therefor, means pivotally supporting said car-body so that it may be rotated upon the truck, and means rotating with the car-body for holding up the end gate out of operative position when the car-body is tilted to dump the load, substantially as described.

5. A dump-car, consisting of a wheeled truck, a tilting car-body open at one end, an edgewise-movable end gate therefor, means pivotally supporting the car-body so that it may be rotated upon the truck, and means rotating with the car-body for holding up the end gate out of operative position when the car-body is tilted to dump the load, substantially as described.

6. A dump-car, consisting of a wheeled truck, a tilting car-body having an open end, an edgewise-movable end gate therefor, a rotary support on which said car-body rests, and means connected with said support for holding up the end gate out of operative position when the car-body is tilted to dump the load, substantially as described.

7. A dump-car, consisting of a wheeled truck, a tilting car-body having an open end, an edgewise-movable end gate therefor, a turn-table on which said car-body is mounted, and means connected with the upper portion of said turn-table for holding up the end gate out of operative position when the car-body is tilted to dump the load, substantially as described.

8. A dump-car, consisting of a wheeled truck, a car-body having an open end, an edgewise-movable end gate therefor, a turn-table on which said car-body rests, a lever for operating said end gate, and means connecting said lever with the rotary portion of said turn-table and arranged to operate said lever to hold the end gate out of operative position when the car-body is tilted, substantially as described.

809,523. **MACHINE FOR CLEARING LAND.** CHARLES H. MCNALLY, Waipahu, Hawaii. Filed May 1, 1905. Serial No. 258,235.

Claim.—1. In a machine of the class described, a cutting-drum, comprising wheels provided with radial slots in their peripheries, a series of knives extending between said wheels and having their ends engaging corresponding slots in the respective wheels and reciprocatory clearing-bars slidably mounted between the knives.

2. In a machine of the class described, a cutting-drum, comprising wheels provided with radial slots in their peripheries, a series of knives extending between said wheels and having their ends engaging corresponding slots in the respective wheels, and means for cleaning said knives, said means comprising flat bars slidable between the knives, and rods connecting diametrically opposite bars.

3. In a machine of the class described, a cutting-drum having a peripheral series of radial knives extending longitudinally of said drum, and reciprocatory bars between the knives for cleaning the latter.

4. In a machine of the class described, a cutting-drum comprising a pair of wheels journaled upon a supporting-axle, a series of radial knives connected at their ends to said wheels, and reciprocatory bars between the knives for cleaning the latter.

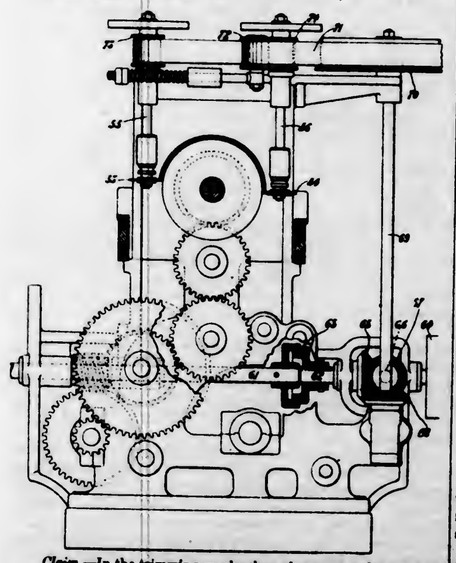
5. A machine of the class described, comprising a frame in three parts hinged together, the end parts of said frame supported on axles with wheels, means for turning said axles for the purpose of guiding the machine, and a bar attached to the sides of the central portion of the frame, on which a cutting-drum revolves when the machine is hauled in either direction by cables attached to the ends of the frame.

6. A machine of the class described, comprising a frame hinged in three parts, axles with wheels supporting the ends of the frame, means for steering the machine, a cutting-drum axled to the central part of the frame, and means for cleaning the knives of said cutting-drum.

7. A machine of the class described, comprising a central rectangular frame A hinged to two triangular end frames B, axles 12 with wheels 13 supporting the outer ends of the end frames B, means for turning the axles 12, and a bar 17 secured to the central frame A and on which a cutting-drum C is adapted to revolve when the machine is hauled in either direction by means of cables attached to clevises 25 at the end of the frames B.

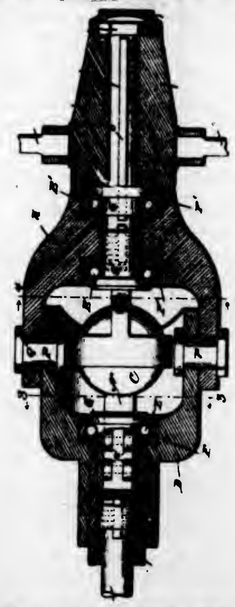
8. In a machine of the class described, a cutting-drum C, comprising the wheels 19 having radial slots 20 similarly arranged in their peripheries, projecting knives 21 secured in corresponding slots 20 by means of hook-bolts 22, a flat bar 23 in each space between the projecting knives 21, and bolts 24 connecting same to the corresponding flat bar 23 on the opposite side of the cutting-drum, substantially in the manner and for the purpose described.

809,524. **TRIMMING MECHANISM OF STEREOTYPE-CASTING MACHINES.** THOMAS M. NORTH, London, England, assignor to Linotype and Machinery Limited, London, England. Filed Feb. 20, 1905. Serial No. 246,607.



Claim.—In the trimming mechanism of apparatus for automatically casting stereotype printing-plates, the combination of the trimming-saws, a shaft adapted to rotate the saws when itself rotated, a two-part first-driven shaft one part in constant operative connection with the first-named shaft and the other part in constant operative connection with the plate-moving mechanism, and a clutch adapted to engage and disengage the two said parts with and from each other.

809,525. **MOTOR-VEHICLE.** ALBERT NUNAMAKER, Cleveland, Ohio. Filed Apr. 26, 1905. Serial No. 257,434.



Claim.—1. The combination, in a mechanism of the class stated, of an axle and a wheel-spindle having non-circular recesses in their ends, and a universal joint between the same having connecting-necks fitting in said recesses and having longitudinal movement therein.

2. The combination, in a mechanism of the class stated, of an axle and a wheel-spindle having non-circular recesses in their ends, and a universal joint having connecting-necks fitting in said recesses and having lengthwise movement therein, and rollers between said necks and the walls of the recesses.

3. In a mechanism of the kind described, in combination, an axle, a wheel-spindle having a universal joint therewith, a casing over the axle, a yoke pivotally connected to the casing and having a sleeve over the spindle, bearings between the spindle and the sleeve, bearing-rings at both the inner and outer ends of the sleeve, upon the outside thereof, the ring at the outer end being screwed on the sleeve for adjustment, and a wheel-hub mounted upon said bearings and connected to the spindle.

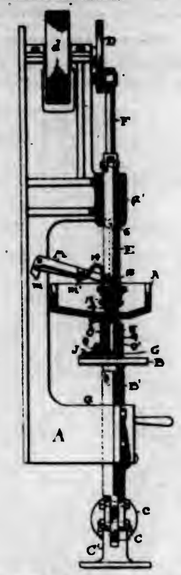
4. The combination with a motor-vehicle axle-casing having at the outer end a pivoted steering member, of a spindle, a wheel mounted thereon to turn therewith, bearing rings and rollers between the spindle and said members, one of which rings backs against the inner end of the wheel-hub, and an adjusting-nut screwed on the end of the spindle against the outer end of the hub.

809,526. **MACHINE FOR FILLING DRY BATTERIES.** PHILIP P. NUNGESSER, Cleveland, Ohio, assignor to The Nungesser Electric Battery Co., Cleveland, Ohio, a Corporation of Ohio. Filed Aug. 5, 1905. Serial No. 272,668.

Claim.—1. In a machine for filling dry batteries, a main frame, a vertically-reciprocating shaft having a fixed bearing in said frame, a ratchet-head rotatably suspended upon the lower end of said shaft, and tamping-bars fixed in the lower portion of said head.

2. In a machine for filling dry batteries, a vertically-reciprocating shaft and actuating means connected with the upper end thereof, a ratchet-head rotatably secured on the lower end of said shaft, a

pawl to engage said ratchet and a pivoted arm carrying said pawl and having a slotted end engaged on said shaft, and tamping-bars fixed in said rotatable head, whereby when said shaft is raised said head and tamping-bars are raised with it.



3. In a machine for filling dry batteries, a vertically-reciprocating shaft and a separable ratchet-head rotatably secured on the lower end thereof, said head comprising an upper ratchet-ring and an inverted cup threaded into said ring, tamping-bars secured in said head, a pawl to rotate said head, and an arm carrying said pawl on the main frame and having a slotted engagement with said vertically-reciprocating shaft

4. In a machine for filling dry batteries, a main frame, a vertically-reciprocating shaft having a straight-line bearing in said frame, said shaft provided with a longitudinal slot between its ends and an axial bore in its lower end opening into said slot, a rod for controlling the carbon element through said bore and slot, and a cross-piece fixing said rod to the main frame and traversing the slot in the said shaft.

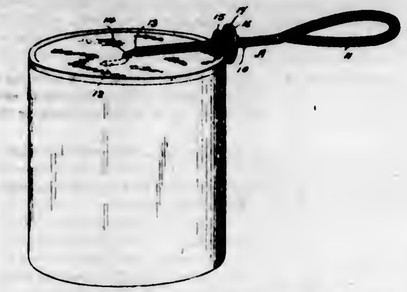
5. In a machine for filling dry batteries, a main frame, a vertically-reciprocating shaft having a fixed vertical bearing in the frame, operating mechanism therefor supported on said frame and linked to the upper end of said shaft, in combination with a ratchet-head on the lower end of said shaft beneath said bearing, tamping-bars secured to said head and a rod to carry a carbon element having a fixed support and extending axially through the lower portion of said shaft and through the head thereon.

6. In a machine for making dry batteries, a main frame and a vertically-reciprocating shaft, in combination with a stand and a cup-holder fixed thereon axially beneath said shaft, a rotatable head on said shaft provided with tamping-bars adapted to extend within said cup-holder, and a hopper for the depolarizing material adjustably supported upon said stand apart from said cup-holder, whereby the hopper is held aloof from the cup and the lining therein.

7. In a machine for filling dry batteries, a main frame and a vertically-reciprocating shaft having a bearing in the front thereof, crank-actuating mechanism linked to the top of said shaft and a rotatable head suspended on the bottom thereof, tamping-bars on said head and pawl-and-ratchet mechanism to rotate said head, and a carbon-supporting rod extending through the lower portion of said shaft and fixed axially in said shaft and independently thereof.

8. In a machine for filling dry batteries, a main frame, a vertically-slidable standard supported by said frame at its front, a counterweighted lever engaging the lower end of said standard, a stand fixed on the top of said standard and a cup-holder fixed on said table having a hinged side, in combination with a vertically-reciprocating shaft, a head rotatable horizontally on said head and tamping-bars fixed to said head, means to rotate said head and a carbon-supporting rod extending axially through said shaft and head and supported independently thereof.

809,527. CAN-OPENER. HERBERT B. RAY, Bridgeport, Conn. Filed Apr. 8, 1905. Serial No. 254,497.

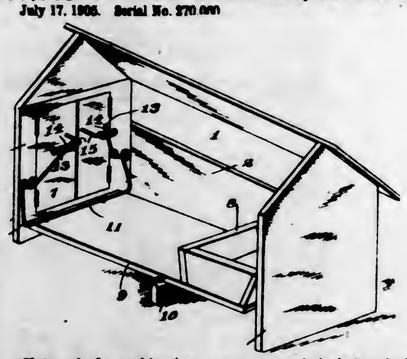


Claim.—1. A can-opener comprising a shank having a prong adapted to be forced through the center of a can-top and a cutter free to both rotate and slide on the shank and comprising a cutting-disk, a rest adapted to engage the edge of a can and a guide-disk adapted to engage the outer face of a can, the relative sizes of said disks being such as to permit the guide-disk to project below the plane of the top edge of the can when the cutting-disk is severing the top of the can.

2. A can-opener comprising a shank having a prong adapted to be forced through the center of a can-top and a cutter free to both rotate and slide on the shank and comprising a cutting-disk convex on its inner face and having a forwardly-projecting cutting edge, for the purpose set forth, a rest to engage the edge of a can and a guide-disk to engage the outer face of said can to retain the cutter in operative position, the relative sizes of said disks being such as to permit the guide-disk to project below the plane of the top edge of the can when the cutting-disk is severing the top of the can.

3. The cutter B comprising a rotary cutting-disk, a rest adapted to engage the edge of a can and a guide-disk adapted to engage the outer face of a can, said disks and rest being integral, and the relative sizes of said disks being such as to permit the guide-disk to project below the plane of the top edge of the can when the cutting-disk is severing the top of the can.

809,528. HEN'S NEST. CHARLES T. REED, Syracuse, Kans. Filed July 17, 1905. Serial No. 270,000



Claim.—1. In combination, a nest-receptacle including inclosing sides, a door for said receptacle, a pivoted platform mounted in the receptacle, a nest upon said platform, a lever pivoted at a point between its ends and connected at one end with the platform, the opposite end of the lever having a loose sliding connection with said door as specified.

2. In combination a nest-receptacle embodying inclosing sides, a door for said receptacle, a platform fulcrumed in the receptacle, a nest mounted on the platform, a cam applied to the door, and a lever connected with the platform and coacting with said cam to effect opening and closing of the door on movement of the platform.

3. In combination, a nest-receptacle embodying inclosing sides, doors for the receptacle, a platform fulcrumed in the receptacle, a nest supported upon the platform at one side of the fulcrum thereof, and at the end remote from the doors, and means for connecting the

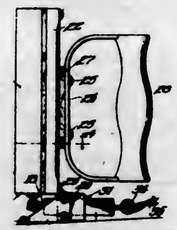
opposite ends of the platform with the doors including levers having a sliding connection with the latter.

4. In combination, a nest-receptacle, doors therefor, a platform pivoted between its ends in the receptacle, engaging members carried by the doors including loops, levers connected with the loops and with the adjacent end of the platform aforesaid, and a nest supported by the opposite end of the platform and upon the opposite side of the fulcrum thereof.

5. In combination, a nest-receptacle, doors therefor, engaging members projected from the inner sides of the doors and including loops inclined with regard thereto, levers pivoted to the receptacle, each lever having one end thereof operating in the loop of the adjacent engaging member, a pivoted platform in the nest-receptacle having operative connection with the levers aforesaid, and a nest supported by said platform.

6. In combination, a nest-receptacle embodying inclosing sides, a door for said receptacle, a platform fulcrumed in the receptacle, a cam attached to one side of the door, and a lever pivoted between its ends to the receptacle, one end of the lever being connected with the platform, the opposite end of the lever having operable connection with the cam of the door, whereby when said platform is moved the door is actuated.

809,529. ELECTRIC LAUNDRY-IRON. EARL H. RICHARDSON, Ontario, Cal., assignor to Pacific Electric Heating Company, Ontario, Cal., a Corporation of California. Filed Apr. 25, 1905. Serial No. 257,286.



Claim.—1. A laundry-iron having a hollow body with extra metal portions in each corner, and means in the metal at each corner for directly heating the exposed corners of the iron.

2. In a laundry-iron, a body with a toe, a core the end of which is in the toe, and resistance-wire wound on the core, whereby the toe is directly electrically heated.

3. In a laundry-iron, a body with toe and heel corners, cores with ends projecting into the toe and heel corners, and resistance-wire wound on the cores.

4. In a laundry-iron, a body with a toe having a recess, a core with a tongue tightly fitting said recess, and resistance-wire wound on the core.

5. In a laundry-iron, a body with a toe having recesses diverging toward the rear, cores with tongues tightly fitting the recesses, and resistance-wire wound on the cores.

6. In a laundry-iron, a body with toe and heel corners having recesses, cores with tongues tightly fitting the recesses, and resistance-wire wound on the cores.

7. A core, the face of which has one flat portion and the remainder convex, and resistance-wire wound on the core.

8. In an electric laundry-iron, a body with a sole, a core, the face of which has one flat portion and the remainder convex, wire wound on the core, the flat face of the core being arranged parallel with and close to the body with an intervening sheet of non-electrical conducting material.

9. In an electric laundry-iron, a hollow body, the heel and toe corner portions of which have recesses, a pair of cores with their ends close together at the front and diverging toward the rear, each end of each core having a tongue which tightly fits in the adjacent corner-recess, and resistance-wire wound on the core.

10. In an electric laundry-iron, a hollow body the heel and toe corner portions of which have recesses, a pair of cores with their ends close together at the front and diverging toward the rear, each end of each core having a tongue which tightly fits in the adjacent corner-recess, resistance-wire wound on the core, and binding-posts projecting through the body with their inner ends lying between the cores, the wire on the cores being connected with the binding-posts.

11. In an electric laundry-iron, a hollow body, the heel and toe corner portions of which have recesses, a pair of cores with their ends close together at the front and diverging toward the rear, each end of each core having a tongue which tightly fits in the adjacent corner-recess, resistance-wire wound on the core, binding-posts projecting through the body with their inner ends lying between the cores, the wire on the cores being connected with the binding-posts, and a suitable cover detachably fastened to the body.

12. In an electric laundry-iron, a hollow body, the heel and toe corner portions of which have recesses, a pair of cores with their ends close together at the front and diverging toward the rear, each end of each core having a tongue which tightly fits in the adjacent corner-recess, resistance-wire wound on the core, binding-posts projecting through the body with their inner ends lying between the cores, the wire on the cores being connected with the binding-posts, and a hood attached to the body and protecting the external portions of the binding-posts and forming a stand for the iron.

13. In an electric laundry-iron, a hollow body, the heel and toe corner portions of which have recesses, a pair of cores with their ends close together at the front and diverging toward the rear, each end of each core having a tongue which tightly fits in the adjacent corner-recess, resistance-wire wound on the core, binding-posts projecting through the body with their inner ends lying between the cores, the wire on the cores being connected with the binding-posts, and a hollow lug formed on the rear of the body for receiving and guiding a switch-plug.

14. In an electric laundry-iron, a hollow body the heel and toe corners of which have recesses, a pair of cores with their ends close together at the front and diverging toward the rear, each end of each core having a tongue which tightly fits in the adjacent corner-recess, resistance-wire wound on the core, binding-posts projecting through the body with their inner ends lying between the cores, the wire on the cores being connected witn the binding-posts, and a hollow lug formed on the rear of the body for receiving and guiding a switch-plug, the lug forming an extension of the hood and combining therewith to form a stand for the iron.

15. In a laundry-iron, a body with a toe, a core the end of which is in the toe, resistance-wire wound on the core, binding-posts carried by the body and connected with the wire, terminals carried by the binding-posts, and a hollow lug on the rear end of the body protecting the ends of the terminals and adapted to receive and guide a switch-plug into contact with the terminals or to hold the plug slidably free from the terminals.

16. In a laundry-iron, a body with a toe, a core the end of which is in the toe, resistance-wire wound on the core, binding-posts carried by the body and connected with the wire, terminals carried by the binding-posts, a hollow lug on the rear of the body protecting the ends of the terminals, and a hood attached to the lug covering the terminals and forming with the lug a stand for the iron.

17. In an electric laundry-iron, a body, electric heating means in said body, terminals for the electric heating means extending outside the body, and a hood protecting the terminals and forming a stand for the iron.

18. In an electric laundry-iron, a body, electric heating means in said body, terminals for the electric heating means extending outside the body, and a hood protecting the terminals and forming a stand for the iron, the free edge of the hood being formed in a roll.

19. In an electric laundry-iron, a body, electric heating means in said body, terminals for the electric heating means extending outside the body, and a hood protecting the terminals and forming a stand for the iron, the free edge of the hood being formed in a roll, the bottom face of which lies below the rear part of the hood whereby the iron is supported in a position tipped back from the perpendicular when stood on end.

20. In combination with an electrically-heated movable implement the current for which is supplied from a stationary point through a wire leading therefrom to the movable implement, means for connecting the wire with the implement embracing a member intermediate the end fastening of the wire and the flexible section of the wire, around which member the wire is wound with one or more turns, whereby as the implement is moved, abrupt bending or kinking of the wire is prevented where the wire joins the implement.

21. In combination with an electrically-heated movable implement, the current for which is supplied from a stationary point through a wire leading therefrom to the movable implement, means for connecting the wire with the implement embracing a switch-plug, a T on the end of the plug, the wire passing over the curved face of the cross-bar of the T.

22. In combination with an electrically-heated movable implement, the current for which is supplied from a stationary point through a wire leading therefrom to the movable implement, means

for connecting the wire to the implement comprising a switch-plug,

2. A diamond having a curved and polished front running en-

teal inner edge cooperating with the outer edge of the rim-flange,

tering-disk arranged within said casing, means for actuating said

for connecting the wire to the implement comprising a switch-plug, a round member over which the conducting-wire is wound, and means on the plug for supporting the round member near the end of the plug, whereby as the implement is moved abrupt bending or kinking of the wire is prevented where the wire joins the implement.

23. In combination with an electrically-heated movable implement the current for which is supplied from a stationary point through a wire leading therefrom to the movable implement, means for connecting the wire to the implement comprising a switch-plug, and a T on the end thereof, the wire passing over the T, whereby as the implement is moved abrupt bending or kinking of the wire is prevented where the wire joins the implement.

24. A laundry-iron having a body with a toe, and means for imparting a relatively greater heat to the toe than to the main part of the body.

25. An electric laundry-iron having a body with a toe, and means for imparting a relatively greater electric heat to the toe than to the main part of the body.

26. A laundry-iron having a body with a toe and heel, and means for imparting a relatively greater heat to the toe and heel corners than to the main part of the body.

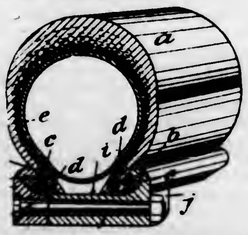
27. An electric laundry-iron having a body with a toe and heel, and means for imparting a relatively greater electric heat to the toe and heel corners than to the main part of the body.

28. In an electrically-heated device, in combination with the element to be heated, a core, resistance for heating the core, and means for securing an uninterrupted heat-conducting connection between the core and body to be heated.

29. In an electrically-heated device, in combination with the element to be heated, a core, resistance for heating the core, the core having intimate contact with the element to be heated.

30. A laundry-iron having a body with a heel, and means for imparting a relatively greater heat to the corners of the heel than to the main part of the body.

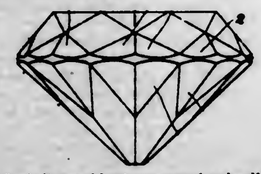
809,530. PNEUMATIC-TIRE COVER. WILLIAM A. SANKEY, Sutton, England, assignor to Frank Reddaway, Manchester, England. Filed Jan. 24, 1905. Serial No. 243,544.



Claim.—1. A tire-cover having beaded edges and a wire embedded in each of said edges, layers of canvas in such tire-cover part of which are secured around the cores of the beaded edges and the remainder around the wires in such edges, substantially as described.

2. The combination in a vehicle-wheel having its periphery provided with lateral recesses, a channeled rim fitting on said periphery and having lugs engaging in the said recesses, said channeled rim being formed of a stationary part and a removable part, bolts passing through the lugs of the removable and stationary parts to hold said parts together and a cover held in said channeled rim, substantially as described.

809,531. DIAMOND. ERNST G. H. SCHENCK, Orange, N. J. Filed May 3, 1904. Serial No. 206,980.



Claim.—1. A diamond having a curved and polished facet running at least part way about the girdle, and provided on its top and bottom with flat polished facets which meet said girdle-facet in curved edges.

2. A diamond having a curved and polished facet running entirely around the same at its girdle and provided at at least one side thereof with flat, polished facets which meet said girdle-facet in curved edges and at obtuse angles.

3. A diamond having a flat polished facet lying in a curved plane and running at least part way around said stone, and provided at at least one side thereof with flat polished facets which meet said facet in curved edges and at obtuse angles.

4. A diamond having a flat, polished facet lying in a circular plane substantially concentric with the axis of the said stone and running entirely around its girdle, and provided on its top and bottom with flat, polished facets which meet said girdle-facet in curved edges and at obtuse angles.

5. A diamond having a flat, polished facet lying in a circular plane running entirely around the same, said stone at at least one side of said facet being provided with a plurality of flat and polished facets each of which meets said circular facet in a curved edge and at an obtuse angle

6. A diamond having a flat, polished facet lying in a circular plane running entirely around the same at its girdle and whose axis is substantially coincident with the axis of said stone, said stone being provided on both top and bottom thereof with a continuous series of flat and polished facets entirely surrounding said girdle-facet, each of which facets meets said girdle-facet in a curved edge and at an obtuse angle.

809,532. DEVICE FOR CUTTING BUTTER. HERMAN SCHRACKENBERG, Hoboken, N. J. Filed Oct. 25, 1904. Renewed July 15, 1905. Serial No. 269,207.

Claim.—1. A device for cutting butter comprising a block having a cutting-wire connected to one side thereof, and a guiding-finger arranged upon the other side opposite the point of attachment, of the wire.

2. A device for cutting butter comprising a block having a projection at one side and a guiding-finger upon the opposite side, a cutting-wire attached to the projection and adapted to engage the guiding-finger, as set forth.

3. A device for cutting butter comprising a block having a concaved inner face and provided with a handle upon the outer face, said block having a projection upon one side and a guiding-finger upon the opposite side, and a cutting-wire connected to the projection and adapted to engage the guiding-finger, said cutting-wire having a handle connected to its free end, as set forth.

809,533. WHEEL-RIM. CHARLES S. SCOTT, Cadiz, Ohio, assignor of one-half to Frank A. Selbering, Akron, Ohio. Filed May 3, 1905. Serial No. 258,649.

Claim.—1. A wheel-rim having a rim-flange with an eccentric outer edge, and a rotatable auxiliary flange codperating therewith, substantially as described.

2. A wheel-rim having a rim-flange with an eccentric outer edge, and a rotatable auxiliary flange having inner and outer edges shaped as eccentric circles, the inner edge of the auxiliary flange being juxtaposed to the outer edge of the rim-flange, substantially as described.

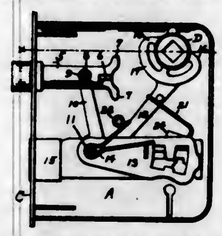
3. A wheel-rim having a rim-flange with an eccentric frusto-conical edge, and a rotatable auxiliary flange, having a frusto-conical inner edge cooperating with the outer edge of the rim-flange, substantially as described.

4. A wheel-rim having a rim-flange with an eccentric outer edge and a filling-piece spaced to leave a groove at the inner face of the rim-flange, in combination with an auxiliary flange rotatable in the groove and codperating with the rim-flange, substantially as described.

5. A wheel-rim having a rim-flange with an eccentric outer edge, a rotatable auxiliary flange codperating therewith, and a pneumatic tire forcing the auxiliary flange against the rim-flange when inflated, substantially as described.

6. A wheel-rim having a rim-flange with an eccentric outer edge, a rotatable auxiliary flange having inner and outer edges shaped as eccentric circles, the inner edge of the auxiliary flange being juxtaposed to the outer edge of the rim-flange, and a pneumatic tire forcing the auxiliary flange against the rim-flange when inflated, substantially as described.

809,534. LATCH. AMOS SHEPARD, Plantsville, Conn., assignor to Russell & Erwin Manufacturing Company, New Britain, Conn., a Corporation. Filed Apr. 4, 1905. Serial No. 253,780.



Claim.—1. The combination of a latch-bolt with a lever operatively connected with the said latch-bolt and pivoted to the latch-case, a roll-back having two wings, a slide for engaging the said lever, the said slide having two arms for engagement with the wings of the said roll-back, and spring-arms acting on the said lever and slide to return the parts to their normal position.

2. The combination of a latch-bolt with a spring-pressed lever operatively connected with the said latch-bolt, a roll-back having two wings, and a spring-pressed slide interposed between the said roll-back and lever and acting to operate the said lever in the direction for withdrawing the latch-bolt when the roll-back is turned in either direction.

3. The combination of a latch-bolt with a spring-pressed lever operatively connected with the said latch-bolt, a roll-back having two wings, and a spring-pressed slide interposed between the said roll-back and lever and having two end faces at one end and one end face on the opposite end, the three end faces of the said slide being in position for engagement with the said wings and lever.

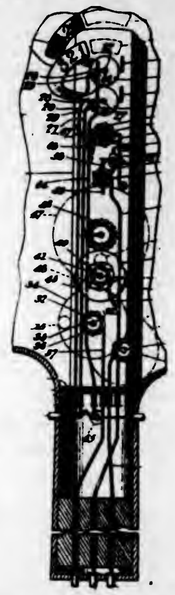
4. The combination of the latch-case with a latch-bolt, a spring-pressed lever pivoted on the tumbler-post of the said latch-case with the free end of the said lever operatively connected with the said latch-bolt, a roll-back, and a spring-pressed slide operatively connecting the said roll-back and lever, whereby the said slide is moved in a direction to withdraw the latch-bolt when the roll-back is turned in either direction.

5. The combination of a latch-bolt with a lever pivoted to the latch-case and operatively connected with the said lever, a roll-back having two wings, a slide interposed between the said roll-back and lever, and a single spring with one arm pressing against the said lever to move it toward the said slide, and with its other arm pressing against the said slide to move it toward the said roll-back.

809,535. COMBINED FAN AND SCORE-CARD. WILL STEEL, Texarkana, Ark. Filed Jan. 12, 1905. Serial No. 240,810.

Claim.—1. In a game-register, a casing provided with a plurality of display-openings, a pointer movable over the face of the casing, registering-dials arranged within said casing, means for actuating said dials for successively displaying a numeral at said openings, a dial-locking mechanism, and means for releasing said locking mechanism, said releasing mechanism also serving to rotate the pointer.

2. In a game-register, a casing provided with a plurality of display-openings, a pointer movable over the face of the casing, registering-dials arranged within said casing, means for actuating said dials for successively displaying a numeral at said openings, a dial-locking mechanism, and means for releasing said locking mechanism and simultaneously rotating the pointer.



3. In a game-register, a casing provided with display-openings, a pointer movable over the face of the casing, a plurality of registering-dials arranged within said casing, means for actuating said dials for successively displaying a numeral at said openings, a dial-locking mechanism, means for releasing said locking mechanism and simultaneously rotating the pointer, and means for returning said dials to their normal position.

4. In a game-register, a casing provided with display-openings, a pointer movable over the face of the casing, registering-dials arranged within the casing, means for actuating said dials for successively displaying a numeral at said openings, a dial-locking mechanism, means for releasing said locking mechanism and simultaneously rotating the pointer, and means for moving said pointer out of operable engagement with the lock-releasing means.

5. In a game-register, a casing provided with display-openings, a plurality of dials carried by the casing, a pointer movable over the face of the casing, an index movable over the back of said casing, means for rotating the pointer and simultaneously actuating some of the dials to successively display a numeral at said openings, and means for operating one of said dials and rotating the index.

6. In a game-register, a casing provided with a handle and having display-openings formed therein, a plurality of dials arranged within the casing, spring-pressed rods for actuating the dials to successively display a numeral at said openings, and push-buttons carried by the handle of the casing and operatively connected to said spring-pressed rods.

7. In a game-register, a casing provided with a handle and having a display-opening formed therein, a plurality of registering-dials arranged within the casing, rods for independently actuating said dials for successively displaying a numeral at said openings, push-buttons carried by the handle, and levers forming a pivotal connection between the rods and the push-buttons.

8. In a game-register, a casing provided with a handle and having display-openings formed therein, a plurality of registering-dials arranged within the casing, a perforated partition extending transversely across the handle, rods extending through the perforations in the partition and engaging said dials for actuating the latter to successively display a numeral at said openings, push-buttons carried by the handle of the casing, levers forming a pivotal connection between the rods and the push-buttons, and springs arranged on the rods and interposed between the levers and said transverse partition.

9. In a game-register, a casing provided with a terminal handle and having a plurality of picture-receiving openings formed in one wall thereof, there being a plurality of display-openings also formed in said wall, a pointer movable over the surface of the casing with a step-by-step movement and adapted to register with the picture-receiving openings, a plurality of registering-dials mounted in the casing, means for actuating said dials for successively displaying a numeral at the display-openings, and means for rotating the pointer.

10. In a game-register, a casing provided with display-openings, a pointer movable over the face of the casing, an index movable over the back thereof, registering-dials carried by the casing, means for actuating said dials to successively display a numeral at said openings, means for locking said dials against backward movement, and means for simultaneously releasing the locking means and dial-actuating means to permit the dials to return to normal position, said releasing means serving to rotate the pointer.

11. In a game-register, a casing provided with display-openings, registering-dials arranged within the casing, spring-pressed rods for actuating said dials to successively display a numeral at said openings, means for locking said dials against backward movement, a toothed rod for releasing the locking mechanism, and means pivoted to said toothed rod and engaging the actuating-rods for disengaging the latter from the dials.

12. In a game-register, a casing provided with display-openings, registering-dials arranged within the casing, spring-pressed rods provided with stop-lugs for actuating said dials to successively display a numeral at said openings, means for locking said dials against backward movement, a toothed rod for releasing said locking mechanism, and a loop pivoted to said toothed rod and engaging the stop-lugs on the spring-rod for disengaging the latter from the actuating-dials.

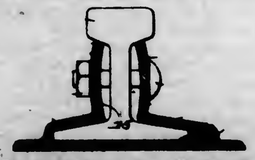
13. In a game-register, a casing provided with display-openings, a pointer movable over the face of the casing, registering-dials arranged within the casing, means for actuating the dials for successively displaying a numeral at said openings, means for locking said dials against backward movement, means for releasing said locking means and simultaneously rotating the pointer with a step-by-step movement, and means for moving the pointer out of operative engagement with the locking means.

14. In a game-register, a casing provided with display-openings, a pointer movable over the face of the casing, registering-dials arranged within the casing, means for actuating the dials for successively displaying a numeral at said openings, a bracket, a toothed wheel journaled in the bracket and carrying the pointer, a rod for rotating the wheel with a step-by-step movement, a cam engaging the bracket, and means for rotating the cam to move the toothed wheel out of operative engagement with said rod.

15. In a game-register, a casing provided with display-openings, a pointer movable over the face of the casing, a plurality of registering-dials arranged within said casing, one of which is provided with transfer-teeth for engaging the teeth of the adjacent dial, means for operating said dials for successively displaying a numeral at said openings, means for locking all of said dials against backward movement, and means for releasing the locking means and simultaneously rotating the pointer.

16. In a game-register, a casing provided with display-openings, a pointer movable over the face of the casing, registering-dials arranged within the casing, means for actuating the dials for successively displaying a numeral at said openings, a spring-bracket, a toothed wheel journaled in the bracket and carrying the pointer, a rod for rotating the wheel with a step-by-step movement, a cam adapted to engage the bracket and provided with an index movable over the back of the casing, and means for rotating the cam to thereby move the toothed wheel out of operative engagement with said rod.

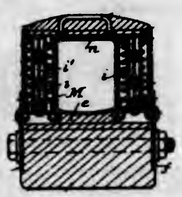
809,536. **RAIL-JOINT.** CHARLES H. STEPHENS, Bartlett, Tex. Filed Aug. 17, 1905. Serial No. 274,699.



Claim.—1. The combination with a rail, of a splice-bar engaging one side of the rail and provided with a lateral extension spaced from the adjacent portion of the splice-bar to form a pocket for the reception of the base of the rail, said extension being provided with a terminal upwardly-projecting flange defining a shoulder adapted to engage the adjacent longitudinal edge of the base of the rail and having its upper and lower faces converging toward the free end of the extension, a mating splice-bar engaging the opposite side of the rail and having a correspondingly-shaped groove formed therein for the reception of the flange, and means for clamping the splice-bars to the rail and in engagement with each other.

2. The combination with a rail, of a splice-bar having one end thereof bowed and engaging one side of the rail and its opposite end provided with a lateral extension spaced from the adjacent portion of the splice-bar to form a pocket for the reception of the base of the rail, said extension being provided with a terminal upwardly-projecting flange defining a vertical shoulder adapted to engage the adjacent longitudinal edge of the base of the rail and having its upper and lower faces inclined in opposite direction toward the free end of the extension, a mating splice-bar having a bowed portion for engagement with the opposite side of the rail and provided with a longitudinal groove corresponding in shape to the flange and adapted to receive the latter, and bolts passing through the rail and bowed portions of the splice-bars for clamping said splice-bars to the rail and in engagement with each other.

809,537. **TIRE FOR WHEELED VEHICLES.** FRANK H. STERLING, London, England. Filed Dec. 6, 1904. Serial No. 235,755.



Claim.—1. The combination, with a wheel-rim, of spiral springs secured around the said rim, bridge-pieces arranged around the said springs, pivotal connections between the adjacent ends of the said bridge-pieces, and flexible connections arranged radially between the said wheel-rim and bridge-pieces and limiting the outward movements of the said bridge-pieces.

2. The combination, with a wheel-rim, of rows of spiral springs secured around the said rim, bridge-pieces bearing directly upon and secured to the outer end portions of the said springs, and links pivotally connecting the adjacent edges of the said bridge-pieces.

3. The combination, with a wheel-rim, of rows of spiral springs secured around the said rim, a series of articulated bridge-pieces connected to the outer end portions of the said springs, and a series of flexible connections arranged radially between the said rim and bridge-pieces.

4. The combination, with a wheel-rim, of rows of spiral springs secured around the said rim, a series of articulated bridge-pieces connected to the outer end portions of the said springs, and cores of elastic material arranged inside the said springs.

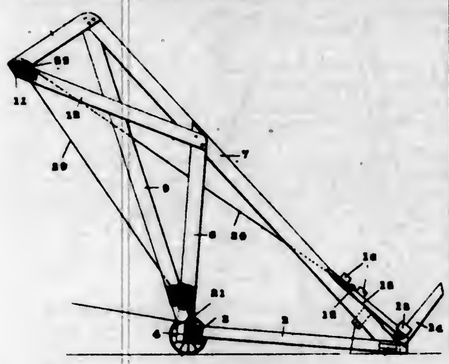
5. The combination, with a wheel-rim, of rows of spiral springs secured around the said rim, a series of articulated bridge-pieces connected to the outer end portions of the said springs, tubular cores of elastic material arranged inside the said springs, and flexible connections arranged radially between the said rim and bridge-pieces inside the said tubular cores.

6. The combination, with a wheel-rim, of a ring secured to the middle portion of the said rim, retaining-plates secured to the sides of the said rim, endless rings secured between the said ring and plates, rows of spiral springs having their inner end portions secured to the said endless rings, and a series of articulated bridge-pieces connected to the outer end portions of the said springs.

7. The combination, with a wheel-rim, of rows of spiral springs secured around the edges of the said rim, a series of articulated bridge-pieces connected to the outer end portions of the said springs, and an inflatable air-tube arranged at the middle part of the said rim between the said rows of springs.

8. The combination, with a wheel-rim, of rows of spiral springs secured around the said rim, a series of articulated bridge-pieces connected to the outer end portions of the said springs, and flexible connections arranged in inclined positions between the said rim and bridge-pieces and preventing the outer portions of the said springs from moving circumferentially of the said rim.

809,538. **HAY-STACKER.** ARGUS M. STEVENS and GEORGE B. STEVENS, Malvern, Kans. Filed Sept. 9, 1905. Serial No. 277,794.



Claim.—1. In a hay-stacker, the combination with a sill-frame, of inclined carrier-tracks supported thereon, delivery-tracks at the upper end of said carrier-track, and an X-shaped truss-frame supporting said delivery-tracks.

2. In a hay-stacker, the combination with a sill-frame, of uprights carried thereby, overhanging carrier-tracks secured to said sill-frame and uprights, delivery-tracks at the upper ends of said carrier-tracks, and an X-shaped truss-frame supporting the upper end of said carrier-tracks and said delivery-tracks.

3. A carrier for hay-stackers comprising an L-shaped frame having runner-beams which straddle the track-beams of the stacker-frame.

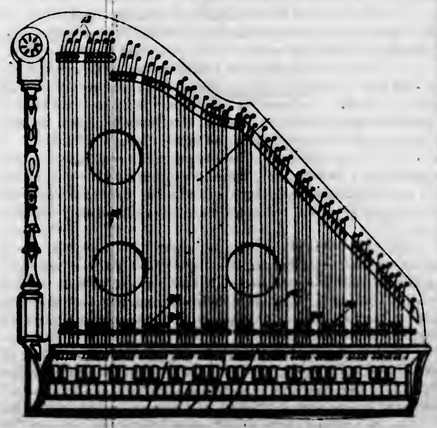
4. A carrier for hay-stackers comprising an L-shaped frame having runner-beams, supporting-rollers carried by said runner-beams, and guides projecting from said runner-beams to hold the carrier in position on the tracks of the stacker-frame.

5. A carrier for hay-stackers comprising an L-shaped frame, and projecting guides on the bed portion thereof, which enter between the tracks of the stacker-frame and guide the carrier in its movements thereon.

6. A carrier for hay-stackers comprising an L-shaped frame having downwardly-projecting wedge-shaped guides adapted to enter between the tracks of the stacker-frame and hold the carrier in position thereon.

7. A carrier for hay-stackers comprising an L-shaped frame, runner-beams adapted to straddle the stacker-tracks, supporting-rollers on the under side of said runner-beams at the rear of the carrier, and antifriction-rollers on the upper side of said runner-beams at the front.

809,539. **MUSICAL INSTRUMENT.** HANS STOCKMEIER, Baltimore, Md. Filed Sept. 18, 1905. Serial No. 278,806.

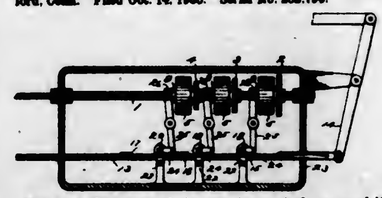


Claim.—1. In a musical instrument, the combination with a sounding-board and strings, of a keyboard, key-actuated levers operable from the keyboard, a pivotally-mounted bell-crank lever having one of its arms connected to one of the levers, a picking-finger carried by the opposite arm of the bell-crank lever, the finger being movable with the lever in one direction, and being movable independently of the lever in the opposite direction, and a bridle for insuring return movement of said finger.

2. In a musical instrument, the combination with the sounding-board and strings, of a picking-finger, a lever carrying the same, said finger having a laterally-extended flange for engagement with the lever in order to limit pivotal movement of the finger in one direction, and a bridle for insuring return movement of the picking-finger to initial position.

3. In a musical instrument, the combination with the sounding-board and strings, of a key-actuated lever, a bell-crank lever operatively connected to said lever, a picking-finger pivotally mounted on said bell-crank lever, and arranged to positively engage with the string during movement in one direction, and moving freely past the string in the opposite direction, a bridle for insuring return of the picking-finger to proper position, and a damper also carried by said bell-crank lever.

809,540. **TRANSMISSION-GEARING.** MORTON C. TALCOTT, Hartford, Conn. Filed Oct. 14, 1905. Serial No. 283,790.



Claim.—1. In a transmission-gearing, a shaft, gears of different diameters loose on the shaft, clutches adapted to connect the gears with the shaft, a bar bearing racks, pinions adapted to be successively rotated by the racks, and connections between the pinions and the clutches for operating the clutches, substantially as specified.

2. In a transmission-gearing, a shaft, gears of different diameters loose on the shaft, a drum keyed to the shaft adjacent to each gear, a clutch-band encircling each drum and connected with the adjacent gear, a wedge movable upon the shaft for tightening each band upon the adjacent drum, a bar bearing racks, pinions adapted to be successively rotated by the racks, and a connection between the pinions and the wedges for moving the wedges when the pinions are rotated, substantially as specified.

3. In a transmission-gearing, a shaft, gears of different diameters loose on the shaft, a clutch for connecting each gear with the shaft, a bar bearing racks, pinions adapted to be successively rotated by the racks, frictional means for retaining the pinions against rotation when disengaged from the racks, and levers connected with the clutches and adapted to be oscillated by the rotations of the pinions, substantially as specified.

4. A power-transmission element consisting of a shaft, a gear loose on the shaft, a lever connected with the gear, a drum fixed to the shaft adjacent to the gear, a band encircling the drum and having one end connected with the gear and the other end attached to the lever that is connected with the gear, and a wedge movable longitudinally on the shaft and adapted to engage the lever for contracting the band upon the drum, substantially as specified.

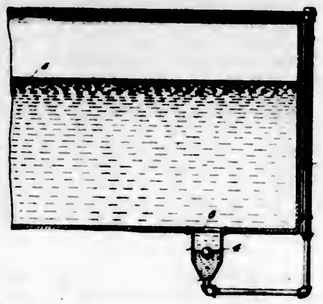
5. In a transmission-gearing the combination of clutches, a bar bearing racks, pinions adapted to be successively rotated by the racks, and connections between the pinions and the clutches for operating the clutches by the rotations of the pinions, substantially as specified.

809,541. **SCISSORS.** RUDOLF THEIS, Solingen, Germany. Filed Jan. 6, 1906. Serial No. 290,896.

Claim.—Scissors provided with a pair of pivoted cutting members of which the first member is perforated back of the pivot, a spring engaging the pivot and extending forwardly and backwardly thereof, the front of the spring bearing directly upon the outer side of the first member in front of the pivot, and the beak of the spring bearing upon the inner side of the second member back of the pivot, whereby

the cutting edges of the members are forced against each other, substantially as specified.

809,542. **OIL-TANK INDICATOR.** WILLIAM TORBT, Jr., San Pedro, Cal., assignor of seven-eighths to T. J. Brundage and one-eighth to Robert K. Brundage, Farmersville, Cal. Filed Feb. 6, 1905. Serial No. 244,515.



Claim.—1. An oil-indicating device comprising a brine-containing valve disposed below the tank containing the oil, brine in said valve; a stopper in said valve having a specific gravity greater than the oil and less than the brine therein; an indicator-tube in communication with said valve; disposed on the outside of the tank containing the oil and brine in the indicator-tube.

2. Means to indicate the level of oil in an oil-tank comprising a valve disposed below and communicating with the oil-tank; a valve-stopper in said valve having a specific gravity greater than oil and less than brine; an indicator-tube in communication with said valve and disposed on the side of the tank containing the oil; brine in said valve and in the indicating-tube.

3. In an oil-indicator having a valve in the bottom thereof with a stopper therein of a specific gravity greater than oil and less than brine and having an indicator-tube in communication therewith located without and below the elevation of the tank containing the oil and having an extension projecting upwardly from said indicator-tube to a point level with the top of the tank containing the oil; brine in said valve and indicator-tube and a light, transparent oil in the extension-pipe above said indicator-tube.

4. In a device to indicate the quantity of crude oil in a tank comprising a valve disposed below the tank and having therein a valve-stopper of a specific gravity greater than the oil and less than the brine and having also an indicator-tube communicating with said valve and having in said indicator-tube and valve a liquid having a specific gravity greater than oil, the herein-described extension-tube disposed above the indicator-tube and having therein a transparent liquid of a like specific gravity with the crude oil.

5. The herein-described means to indicate the level of crude oil in a tank comprising the valve disposed below and communicating with the tank 1, the indicator-tube 3 communicating with said valve; a stopper 4 in said valve having a specific gravity greater than crude oil and less than brine; brine in said valve and in said indicator-tube.

809,543. **PIG-BROODER.** HENRY B. VAIL, Arlington, Ohio. Filed June 20, 1905. Serial No. 266,183.

Claim.—1. In a device of the class described, the combination of, an animal-pen with a stall disposed therein and with its walls supported above the floor of the pen.

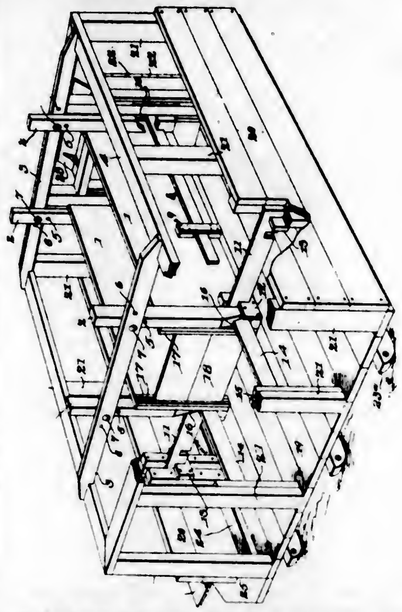
2. In a device of the class described, the combination of, an animal-pen with a stall suspended within the pen and with its walls above the floor of the pen.

3. In a device of the class described, the combination of, an animal-pen, a stall suspended within and with its walls above the floor of the pen, and means for bracing the stall from displacement.

4. In a device of the class described, the combination of, an animal-pen, a stall disposed within and with its walls above the floor of the pen, and means for varying the width of the stall.

5. In a device of the class described, the combination of, an animal-pen, a stall suspended within and with its walls above the floor of the pen, and means for varying the width of the stall.

6. In a device of the class described, the combination of, an animal-pen, a stall suspended within and with its walls above the floor of the pen, means for bracing the stall against displacement, and means for varying the width of the stall.



7. In a device of the class described, an animal-pen, a pair of beams removably extending across the pen, and a pair of stall-walls suspended from the beams and with their lower edges above the floor of the pen.

8. In a device of the class described, an animal-pen, a pair of beams removably extending across the pen, a pair of stall-walls suspended from the beams and with their lower edges above the floor of the pen, an end gate disposed to close the open end of the stall, and means for bracing the stall against displacement.

9. In a device of the class described, an animal-pen, a pair of beams removably extending across the pen, a pair of stall-walls pivotally suspended from the beams and with their lower edges above the floor of the pen.

10. In a device of the class described, the combination of, an animal-pen, a pair of beams removably extending across the pen, a pair of stall-walls pivotally suspended from the beams and with their lower edges above the floor of the pen, an end gate disposed to close the open end of the stall, and means for bracing the stall against displacement.

11. In a device of the class described, an animal-pen, a foldable stall, and means for suspending the stall within the pen with a space between the lower edge of the stall-walls and the pen-floor.

12. In a device of the class described, the combination of, an animal-pen, a covered feed-box opening into said pen, a foldable stall, and means for suspending the stall within the pen with an open end registering with the feed-box and with an open space between the lower edge of the stall-walls and the pen-floor.

13. In a device of the class described, the combination of, an animal-pen, a foldable stall, means for suspending the stall within the pen with an open space between the lower edge of the stall-walls and the pen-floor, and means for bracing the stall against displacement.

14. In a device of the class described, the combination of, an animal-pen, a covered feed-box opening into said pen, a foldable stall, means for suspending the stall within the pen with an open end registering with the feed-box and with an open space between the lower edge of the stall-walls and the pen-floor, and means for bracing the stall against displacement.

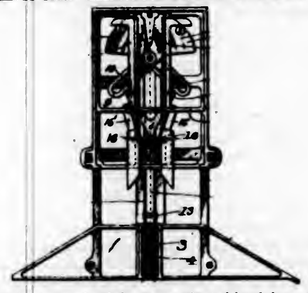
15. In a device of the class described, the combination of, an animal-pen, a folding and adjustable stall, means for suspending the stall within the pen with a space between the lower edge of the stall-walls and the pen-floor, and means for varying the width of the stall.

16. In a device of the class described, the combination of, an animal-pen, a covered feed-box opening into said pen, a foldable and adjustable stall, means for suspending the stall within the pen with an open end registering with the feed-box and with an open space between the lower edge of the stall-walls and the pen-floor, and means for varying the width of the stall.

17. A device of the class described comprising, an animal-pen, a foldable and adjustable stall, means for suspending the stall within the pen with an open space between the lower edge of the stall-walls and the pen-floor, means for securing the stall against displacement, and means for varying the width of the stall.

18. A device of the class described comprising, an animal-pen, a covered feed-box opening into said pen, a foldable and adjustable stall, means for suspending the stall within the pen with an open end registering with the feed-box and with an open space between the lower edge of the stall-walls and the pen-floor, means for securing the stall against displacement, and means for varying the width of the stall.

809,544. **GATE-LATCH.** GEORGE WARNER, Dearborn, Mont. Filed Mar. 25, 1899. Renewed June 19, 1905. Serial No. 266,043.



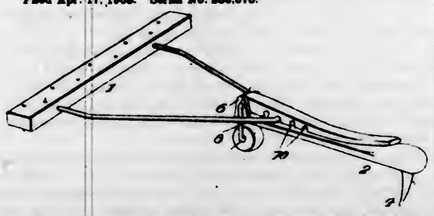
Claim.—1. A gate-latch having a pivoted latch-bar adapted to engage by gravity in its engaging recess, in combination with a vertically-moving stop-bolt, a trigger mechanism for said stop-bolt arranged in the path of the latch-bar and adapted to be operated by the latch-bar in a closing movement of the gate, to release the stop-bolt and allow the same to move downward into a position to prevent a rebound of the gate, substantially as set forth.

2. A gate-latch comprising in combination, a latch-bar, a pair of vertically-movable stop-bolts, locking-triggers for said stop-bolts, a pair of pivoted levers for raising said stop-bolts, and means whereby the movement of the latch-bar operates said triggers, substantially as set forth.

3. A gate-latch comprising in combination, a latch-bar, a central recess in the latch-frame for receiving said bar, a vertically-movable stop-bolt, a locking-trigger for said stop-bolt, and means whereby the movement of the latch-bar in the central recess of the latch-frame operates said trigger, substantially as set forth.

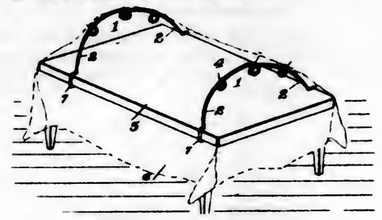
4. A gate-latch comprising in combination, a latch-bar, a central recess in the latch-frame for receiving said bar, a pair of vertically-movable stop-bolts, locking-triggers for said stop-bolts, a pair of pivoted levers for raising said stop-bolts, and means whereby the movement of the latch-bar in the central recess of the latch-frame operates said trigger, substantially as set forth.

809,545. **CARPET-STRETCHER.** SERBEN J. WEVER, Sheller, Ill. Filed Apr. 17, 1905. Serial No. 256,075.



Claim.—In a carpet-stretcher, the combination of a floor-dog, a carpet-engaging member, a lever, connecting means between the lever and the carpet-engaging member, a pivot-rod carried by the floor-dog and forming a pivot for the lever, said rod being extended and formed with a journal member beneath the floor-dog, and a roller mounted upon said journal member.

809,546. **TABLE-SPREAD SUPPORT.** SERBEN J. WEVER, Sheller, Ill. Filed Aug. 23, 1905. Serial No. 275,469.



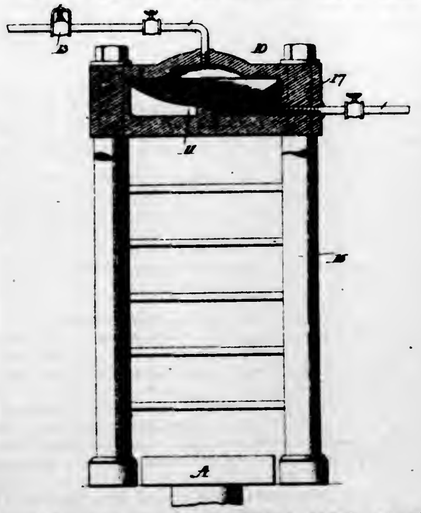
Claim.—1. A table-spread support comprising a frame embodying integral spring-arms, hooks carried by the said arms for engagement with a table and so connected with the arms as to be held in such engagement by the spring action thereof, and members carried by the hooks for holding the frame in an upright position.

2. A table-spread support comprising a frame composed of oppositely-extending arms, hooks at the ends of said arms for engagement with a table to attach the frame thereto, and extensions projecting laterally from the hooks for coöperation with the object engaged thereby to brace the frame and hold it in an upright position when affixed to the table.

3. A table-spread support comprising a frame composed of oppositely-extending arms, and hooks at the ends of said arms for engagement with a table to attach the frame thereto, each hook being extended laterally to form a brace extension for holding the frame in an upright position, the brace extensions of the hooks projecting in opposite directions.

4. As a new article of manufacture, a table-spread support comprising an integral frame embodying oppositely-extending curved arms made from a single length of spring-wire, the wire being coiled upon itself at a point between its ends to form a spring for the arms, each arm being coiled to form a spring-loop, the lower extremities of each arm being formed with an integral hook, the terminals of each hook being extended laterally in opposite directions to form brace members for the purpose specified.

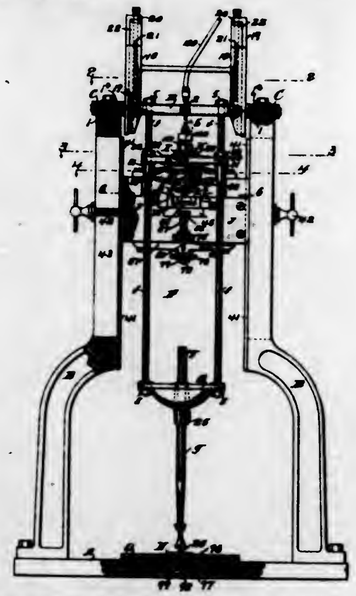
809,547. **HEATING DEVICE FOR OIL-PRESSES.** JAMES W. WINFREY, Ashdown, Ark. Filed May 11, 1905. Serial No. 260,001.



Claim.—An oil-press having a hollow head-block, and a plurality of strengthening-ribs arranged within the interior of the block

fer bracing the lower central portion of the latter, said ribs being inclined upward from the central portion toward the outer edges of said block, a steam-supply pipe entering the upper portion of the hollow head, and an exhaust-pipe leading from the lower portion of said head, the supply-pipe being provided with a reducing-valve for governing the quantity of steam admitted to said head.

809,548. MATRIX AND PUNCH CUTTING MACHINE. LINN B. BENTON, New York, N. Y., assignor to American Type Founders Company, New York, N. Y., a Corporation of New Jersey. Filed Feb. 17, 1899. Serial No. 705,735.



Claim.—1. The combination with swinging tracing-frame F having pairs of pivots 1, 2 forming a universal joint, and a follower actuated by said frame, one of said pairs of pivots being adjustable toward and from the follower independently of the other pair of said pivots, of screws for adjusting said adjustable pivots, and removable bearing-blocks limiting the movement of the pivots by the screws, substantially as described.

2. The combination with swinging tracing-frame F and plate E by which it is suspended, of frame D in which plate E is pivoted, and vertical pivot-bars 19 mounted on pivots 1 in the machine-frame and on which the frame D is vertically adjustable with plate E, substantially as described.

3. The combination with swinging tracing-frame F and suspending frame D and plate E, of vertical pivot-bars 19 having arms 20 and screws 21 passing through said arms for adjusting the frame D on the pivot-bars 19, substantially as described.

4. In a matrix-cutting machine, a matrix-holder having independently-adjustable side gages for the matrix-blank, and an end gage adjustable independently of the side gages, substantially as described.

5. In a matrix-cutting machine, a matrix-holder having independently-adjustable side gages for the matrix-blank, an end gage adjustable independently of the side gages, a top gage, and means for clamping the matrix-blank against the top gage and end gage, substantially as described.

6. In a matrix-cutting machine, a matrix-holder having independently-adjustable side gages an adjustable top gage and an adjustable end gage for the matrix-blank, and means for clamping the matrix-blank against the top gage and end gage, substantially as described.

7. In a matrix-cutting machine, a matrix-holder having independently-adjustable side gages and a top gage for the matrix-blank, and a vertical gage against which the matrix-blank is set up, and a clamp adapted to force the matrix-blank vertically against the lower face of the top gage and horizontally against the vertical gage, substantially as described.

8. In a matrix-cutting machine, a matrix-holder having a top gage for the matrix-blank, and a vertical gage against which the matrix-blank is set up, and a wedge-plate adapted to be forced under the matrix-blank and toward the vertical gage, substantially as described.

9. A matrix-holder having the base *k* provided with side flanges *k'*, *k²*, adjusting-screws 83, 84 in said flanges, gage-blocks 86, 87, a top gage, and adjustable end gage 91, substantially as described.

10. A matrix-holder having the base *k* provided with side flanges *k'*, *k²*, adjusting-screws 83, 84 in said flanges, gage-blocks 86, 87, an adjustable top gage, and adjustable end gage 91, substantially as described.

11. A matrix-holder having the base *k* provided with side flanges *k'*, *k²*, adjusting-screws 83, 84 in said flanges, gage-blocks 86, 87, adjustable top gages 88, 89, and adjustable end gage 91, substantially as described.

12. A matrix-holder having the base *k* provided with side flanges *k'*, *k²*, adjusting-screws 83, 84 in said flanges, gage-blocks 86, 87, adjustable top gages 88, 89, adjustable end gage 91, and wedge-plate 85 on the base *k*, substantially as described.

13. A matrix-holder having a top gage and a vertical gage for one edge of the matrix-blank, and wedge-plate 85 adapted to move toward the vertical gage below the matrix-blank, substantially as described.

14. A matrix-holder having a top gage and an adjustable end gage 91, gage-block 92 behind the gage 91, and wedge-plate 85 moving toward the gage 91, substantially as described.

15. The combination with standards B, of vertically-adjustable block J supported on said standards, vertically-adjustable block 50 set into block J, and a work-carrying block sliding into a groove in block 50, substantially as described.

16. The combination with block 50 having a groove and bolt 54 having head 55 entering said groove, of a work-carrying block sliding in said groove and having a T-groove 51 receiving head 55, and means for adjusting bolt 54 to lock the work-carrying block down on block 50, substantially as described.

17. The combination with block 50, of screw-threaded sleeve 70 secured thereto, adjusting-bolt 72 entering said sleeve, a micrometer-disk for rotating said bolt in the sleeve to move the latter, and screw-sleeve 77 inclosing the bolt 72 for moving the bolt longitudinally with the disk and sleeve, substantially as described.

18. The combination with block 50, of screw-threaded sleeve 70 secured thereto, adjusting-bolt 72 entering said sleeve, a micrometer-disk for rotating said bolt, screw-sleeve 77 for moving the bolt longitudinally with the disk and sleeve, and nut 79 on the bolt outside the sleeve 77, substantially as described.

19. The combination with a swinging tracing-frame, and pivots 1, 1, and 2, 2, by which the frame is mounted, of a tracer for controlling the frame, a follower actuated by the frame, means for adjusting one set of said pivots independently of the other set and of the follower to vary one component of the tracing movement relatively to the other component in transmission to the follower, and a pattern-holder adjustable angularly in the plane of tracing movement, substantially as set forth.

20. The combination with a swinging tracing-frame, and pivots 1, 1, and 2, 2, by which the frame is mounted, of a tracer for controlling the frame, a follower actuated by the frame, means for adjusting one set of said pivots independently of the other set and of the follower to vary one component of the tracing movement relatively to the other component in transmission to the follower, and a pattern-holder and work-holder adjustable angularly in the plane of tracing movement, substantially as set forth.

21. The combination with swinging tracing-frame F, and pivots 1, 1, and 2, 2, by which the frame is suspended above the follower, of a follower actuated by the frame, and means for adjusting one set of said pivots vertically independently of the other set and of the follower to vary one component of the tracing movement relatively to the other component in transmission to the follower, and a pattern-holder adjustable angularly in the plane of tracing movement, substantially as described.

22. The combination with swinging tracing-frame F, pivots 1, 1, and 2, 2, by which the frame is suspended, and a follower actuated by the frame, of means for adjusting one set of said pivots vertically independently of the other set and of the follower to vary one component of the tracing movement relatively to the other component in transmission to the follower, and a pattern-holder adjustable angularly in the plane of tracing movement and a tracer having its tracing portion oblong in cross-section with its two dimensions such as to compensate for the difference between the ratios in which the two components of the tracing movement are modified, substantially as described.

23. The combination with a tracer, a pattern, a universal joint having axes movable relatively to each other a swinging frame suspended from said universal joint and actuated by the tracing movement, and a follower actuated by said swinging frame to reproduce a pattern, of means for varying the relative angular position of the frame and pattern in planes parallel with the plane of tracing movement, and means for adjusting the universal joint to vary the ratios in which the components of the tracing movement are transmitted from the tracer to the follower, to produce back-sloped or italicized designs, substantially as described.

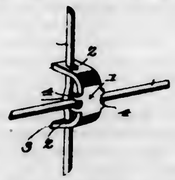
24. The combination with a tracer, a pattern, a universal joint having axes movable relatively to each other a swinging frame suspended from said universal joint and actuated by the tracing movement, and a follower actuated by said swinging frame to reproduce a pattern, of means for adjusting the work and the pattern angularly to the frame in planes parallel with the plane of tracing movement, and means for adjusting the universal joint to vary the ratios in which the components of the tracing movement are transmitted from the tracer to the follower, to produce back-sloped or italicized designs, substantially as described.

25. The combination with a tracer, a universal joint having axes movable relatively to each other a swinging frame suspended from said universal joint and actuated by the tracing movement, and a follower actuated by said swinging frame to reproduce a pattern, of a pattern-holder rotatable in a plane parallel with the plane of tracing movement, and means for adjusting the universal joint to vary the ratios in which the components of the tracing movement are transmitted from the tracer to the follower, to produce back-sloped or italicized designs, substantially as described.

26. The combination with a tracer, a universal joint having axes movable relatively to each other a swinging frame suspended from said universal joint and actuated by the tracing movement, and a follower actuated by said swinging frame to reproduce a pattern, of means for adjusting the work and the pattern angularly to the frame in the plane of tracing movement including a work-holder and a pattern-holder, both rotatable in planes parallel with the plane of tracing movement, and means for adjusting the universal joint to vary the ratios in which the components of the tracing movement are transmitted from the tracer to the follower, to produce back-sloped or italicized designs, substantially as described.

27. The combination with a support having a circular unthreaded opening with an enlarged outer threaded portion, of pivot-screw 1 therein having a reduced unthreaded pivot portion and enlarged screw-head, and set-screw 1ª engaging the unthreaded portion of the pivot-screw 1, substantially as described.

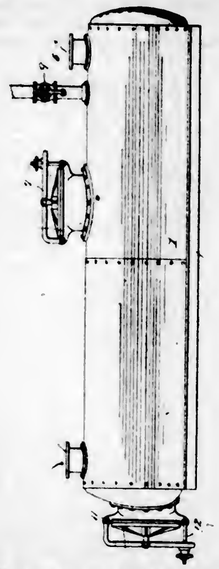
809,549. WIRE-FENCE LOCK. GOTTLOB W. BEUTELL, San Diego, Cal. Filed Feb. 16, 1905. Serial No. 245,986.



Claim.—1. As a new article of manufacture, a lock for crossed wires comprising parallel arms separated by a space greater than the thickness of the member to be spanned and provided with alined openings exceeding the diameter of the member to be received therethrough, a back connecting the arms at one end of the device and the other ends of the arms being free and beveled, said arms capable of being bent at their connection with the back, and a seat carried by the back and opening in the direction of the open side of the lock.

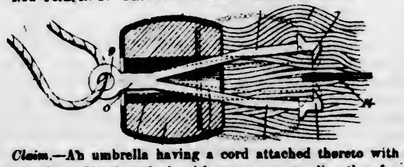
2. A substantially U-shaped metallic lock for crossed wires having its arms separated by a space exceeding the diameter of the wire to be spanned and provided with alined openings exceeding the diameter of the wire to be received therethrough, the free ends of the arms being beveled upon their inner sides, and spaced projections carried by each edge of the back and extending toward the open side of the device, each pair of projections being spaced to snugly receive a wire, and the arms capable of being bent apart upon their connections with the back.

809,550. PROCESS OF MAKING BORIC ACID, &c. HENRY BLUMENAU, Jr., Daggett, Cal., assignor to American Borax Company, Pittsburg, Pa., a Corporation of California. Filed Mar. 24, 1905. Serial No. 251,207.



Claim.—The process of producing boric acid, borax, or the like, consisting in generating sulfur dioxid continuously by burning sulfur in a vessel, supplying said vessel continuously with air under pressure, introducing sulfur into the vessel without interrupting the process, temporarily diverting a portion of the sulfur dioxid to the outside atmosphere during the introduction of the sulfur, leading the sulfur-dioxid gas into the presence of ore of the character described, which is finely divided and mixed with water in suitable proportions, resulting in decomposing the ore and freeing boric acid or the like, which is taken up by the water in solution, and separating the product by evaporation.

809,551. UMBRELLA ATTACHMENT. MARGARET A. BRUNNER, New York, N. Y. Filed Mar. 20, 1905. Serial No. 251,165.



Claim.—A'n umbrella having a cord attached thereto with a tassel, said tassel having a body with streamers extending therefrom, and a fastening device passing through said body and concealed by said streamers.

809,552. WOODWORKING-MACHINE. JOHN BUFFELEN, Tacoma, Wash. Filed Sept. 20, 1904. Serial No. 224,481.

Claim.—1. In a woodworking-machine, the combination of a fixed cutting-tool, an adjustable track, a carriage adapted to hold the wood to be worked mounted on said track, and adjustable legs supporting each end of said carriage upon said track whereby the position of the work on the carriage relatively to the cutting-tool can be varied; with means for rotating the work as it travels.

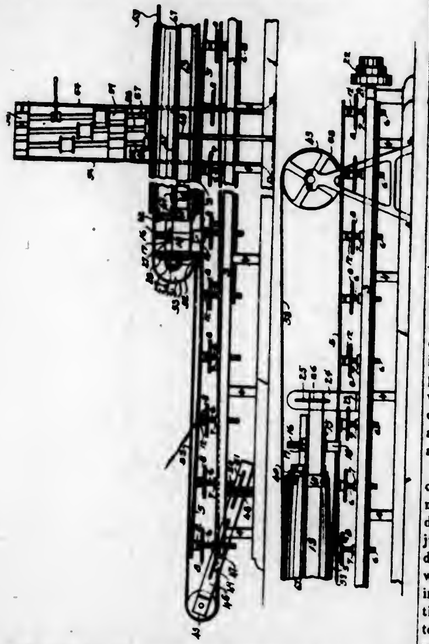
2. In a woodworking-machine, the combination of a fixed cutting-tool, an adjustable track, a carriage supported at its ends by said track and carrying the object to be operated on, a feed-screw beside the track, a traveling nut on said screw, and a pin-and-slot connection between said carriage and said traveling nut whereby said carriage is forced along said track irrespective of the adjustment of said track.

3. In a woodworking-machine, the combination of a fixed cut-

17. The combination of the base, vertically-adjustable screw-

screws attached to the sides thereof

3. In a woodworking-machine, the combination of a fixed cutting-tool, an adjustable track, a carriage adjustably supported at its ends upon and relatively to said track, a feed-screw and traveling nut thereon, and a pin-and-slot connection between said carriage and said traveling nut whereby said carriage is moved along said track irrespective of the adjustment of said track and of said carriage; with means for rotating the work as it travels.



4. In a woodworking-machine, the combination of a fixed tool, an adjustable track, a carriage supported at its ends by said track, a feed-screw beside the track, a traveling nut on said screw, an upwardly-extending arm secured to said traveling nut and having a slot therein, and a roller-pin secured to said carriage and engaging in said slot whereby the longitudinal motion of said traveling nut is communicated to said carriage irrespective of the vertical movements of the carriage.

5. In a woodworking-machine, the combination of a fixed cutting-tool, a pair of parallel bendable rails, a series of screw-posts for bending and adjustably supporting each of said rails, operative means connecting the screw-posts in one series with the corresponding opposite screw-posts in the other series whereby the opposite posts may be simultaneously and correspondingly adjusted, and a traveling carriage adapted to hold the wood to be worked and being supported at each end by said rails; with means for rotating the work as it travels.

6. In a woodworking-machine, the combination of a carriage, rotatably mounted face-plates thereon adapted to hold an article to be turned, a knife-holder on the carriage adjacent said face-plates and movable radially thereof, a knife mounted on said holder, a spring adapted to move the holder and withdraw said knife from the article to be turned, and means adapted to engage the holder and move the knife into contact with the article against the action of said spring as the carriage moves, with means for rotating the work as it travels, substantially as described.

7. In a machine for turning columns, the combination of a track, means for varying it vertically, a carriage, adjustable screws supporting and guiding the carriage on the track, and means on said carriage for engaging and supporting the column to be operated upon at its opposite ends with means for rotating the work as it travels.

8. In a machine for turning columns, the combination of a track, means for varying it vertically, a carriage, adjustable screws supporting and guiding the carriage on the track, and means on said carriage for engaging and supporting the column to be operated upon at its opposite ends: with means for rotating the column on the carriage during its travel, means for moving said carriage along said track, and a rotating cutting-tool adjacent to the path of the carriage and stationary relative thereto, adapted to operate upon the column as the latter moves therepast.

9. In combination, a base, a horizontally-disposed track thereon, means for vertically adjusting the track relative to the base, a horizontally-disposed carriage provided with vertically-adjustable rollers running upon said track; and rotatable face-plates on said carriage, adapted to support the object to be operated upon; with a feed-screw, a traveling nut thereon, and a loose connection between said nut and the carriage, for reciprocating the carriage on the track irrespective of the adjustment thereof, and a cutter adapted to operate on the object as it is moved therepast, substantially as described.

10. In a machine for turning wooden columns, the combination of a base, a horizontally-arranged track supported on said base, means for adjusting the track vertically relative to the base, a horizontally-disposed column-supporting carriage provided with rollers mounted on and guided by said track, and independently-adjustable column-supporting devices or heads on said carriage between which the object to be operated on is mounted; with a rotary cutting-tool adjacent to the carriage and adapted to operate upon the column as it is moved therepast, and means for rotating said column as it is moved past the cutter, substantially as described.

11. In a machine for turning columns, the combination of a base, a track mounted thereon, means for adjusting all or part of the track, a carriage supported on and guided by said track, rotatable devices on said carriage for supporting the column to be operated upon at its opposite ends, means for varying the relative height of said supporting devices, and means for moving said carriage along said track; with a stationary series of rotary cutting-tools adjacent to the path of the carriage and adapted to successively operate upon the column as the latter is moved therepast, and means for rotating said column as it is moved past the cutter, substantially as described.

12. In a machine for turning wooden columns, the combination of a base, a horizontally-arranged track supported on said base, means for vertically bending or undulating the track, a horizontally-disposed carriage, adjustable screw-legs provided with rollers adjustably supporting the carriage on said track, column-supporting devices on said carriage adjustable one toward the other and between which the column is mounted, and means for rotating said supporting devices during the linear movement of the carriage; with a cutting-tool adjacent to the path of the carriage and stationary relative to the base adapted to operate upon the columns as it is moved therepast, substantially as described.

13. In a machine for turning wooden columns, the combination of a base, a horizontally-arranged vertically-bendable track supported on said base, a horizontally-disposed carriage provided with adjustable rollers mounted on and guided by said track, and rotatable supporting devices on said carriage between which the object to be operated on is mounted; with a horizontally-arranged feed-screw, and a traveling nut thereon having a sliding engagement with the carriage; and a cutting-tool adjacent to the carriage adapted to operate upon the objects, substantially as described.

14. In combination, a base, a horizontally-disposed track thereon, adjustable screws for supporting and vertically adjusting the track relative to the base, a horizontally-disposed carriage provided with vertically-adjustable rollers running upon said track; rotatable face-plates on said carriage, adapted to support the object to be operated upon; a rotary cutting-tool mounted beside the path of the carriage, and adapted to operate upon the object on the carriage as it moves therepast and means for rotating the work as it travels, substantially as described.

15. In combination, a base, a horizontally-disposed track thereon, means for adjusting the track relative to the base, a horizontally-disposed carriage moving upon said track; rotatable face-plates on said carriage adapted to support the object to be operated upon, a pulley mounted on the carriage, gearing between said pulley and one of the face-plates, pulleys at opposite ends of the frame, and an endless belt or rope running over said pulleys to impart rotation to the object, a cutting-tool mounted beside the path of the carriage, and means for rotating said tool to operate upon the object on the carriage as it is moved therepast, substantially as described.

16. In combination, a base, a horizontally-disposed track thereon, screws for supporting and vertically adjusting the track relative to the base, a horizontally-disposed carriage running upon said track; rotatable face-plates on said carriage adapted to support the object to be operated upon; means for reciprocating the carriage on the track, a cutting-tool mounted in a frame beside the path of the carriage, and means for rotating said tool to operate upon the object on the carriage as it is moved therepast, substantially as described.

17. The combination of the base, vertically-adjustable screws attached to the sides thereof, a vertically-bendable track supported on said screws; a reciprocating carriage provided with vertically-adjustable carrying-rollers mounted on said track; rotatable face-plates at the ends of the carriage adapted to carry the column to be operated on; a pulley mounted on said carriage, gearing between the pulley and the adjacent face-plate; fixed and adjustable pulleys at opposite ends of the base-frame, an endless rope running over said pulleys and that on the carriage, a driven pulley for driving said rope; and means for reciprocating said carriage, substantially as described.

18. In combination, a base, a horizontally-disposed track thereon, means for vertically adjusting the track, a horizontally-disposed carriage running upon said track; rotatable heads or face-plates on said carriage adapted to support the object to be operated upon, a pulley mounted on the carriage, gearing between said pulley and one of the face-plates, pulleys at opposite ends of the frame, and an endless belt or rope running over said stationary and moving pulleys to impart rotation to the object, a cutting-tool mounted beside the path of the carriage adapted to operate upon the object on the carriage as it is moved therepast, substantially as described.

19. In combination, a base, a horizontally-disposed track thereon, adjustable screws for supporting and vertically adjusting the track relative to the base, a horizontally-disposed carriage provided with vertically-adjustable rollers running upon said track; rotatable heads or face-plates on said carriage, adapted to support the object to be operated upon, a pulley mounted on the carriage, gearing between said pulley and one of the face-plates, pulleys at opposite ends of the frame, and an endless belt or rope running over said stationary and moving pulleys to impart rotation to the object, a series of cutting-tools mounted in a frame beside the path of the carriage and fixed relatively thereto, and means for rotating said tools to operate upon the object on the carriage as it is moved therepast, substantially as described.

20. In combination, a base, a horizontally-disposed track thereon, adjustable screws for supporting and vertically adjusting the track relative to the base, a horizontally-disposed carriage provided with vertically-adjustable rollers running upon said track; rotatable heads or face-plates on said carriage, adapted to support the object to be operated upon, a feed-screw, a traveling nut thereon, and loose connections between said nut and the carriage for reciprocating the carriage on the track, a series of cutting-tools mounted in a frame beside the path of the carriage and fixed relatively thereto, and means for rotating said tools to operate upon the object on the carriage as it is moved therepast, substantially as described.

21. In combination, a base, a horizontally-disposed track thereon, adjustable screws for supporting and vertically adjusting the track relative to the base, a horizontally-disposed carriage provided with vertically-adjustable rollers running upon said track; rotatable heads or face-plates on said carriage, adapted to support the object to be operated upon, a feed-screw, a traveling nut thereon, and loose connections between said nut and the carriage for reciprocating the carriage on the track; a cutting-tool beside the path of the carriage adapted to operate upon the object on the carriage as it is moved therepast, substantially as described.

22. In combination, a base, a horizontally-disposed track thereon, adjustable screws for supporting and vertically adjusting the track relative to the base, a horizontally-disposed carriage provided with vertically-adjustable rollers running upon said track; rotatable heads or face-plates on said carriage, adapted to support the object to be operated upon, a pulley mounted on the carriage, gearing between said pulley and one of the face-plates, pulleys at opposite ends of the frame, and an endless belt or rope running over said stationary and moving pulleys to impart rotation to the object; means for reciprocating the carriage on the track; cutting-tools mounted in a frame beside the path of the carriage and fixed relatively thereto, and means for rotating said tools to operate upon the object on the carriage as it is moved therepast, substantially as described.

23. The combination of the base, vertically-adjustable screws attached to the sides thereof, a vertically-bendable track supported on said screws; a reciprocating carriage provided with vertically-adjustable carrying-rollers mounted on said tracks; rotatable face-plates at the ends of the carriage adapted to carry the column to be operated on; means for reciprocating said carriage comprising a longitudinal screw-shaft in the frame, a traveling nut thereon, a slidable connection between said nut and the carriage, and means for rotating said screw; with a rotatable cutter adjacent to the path of the carriage adapted to operate upon the object mounted on the carriage as it moves therepast.

24. The combination of the base, opposite vertically-adjustable screws attached to the sides thereof, opposite vertically-bendable tracks supported on said screws; a reciprocating carriage provided with vertically-adjustable carrying-rollers mounted on said tracks; rotatable face-plates at the ends of the carriage adapted to carry the column to be operated on; a pulley mounted on said carriage, gearing between the pulley and the adjacent face-plate; fixed and adjustable pulleys at opposite ends of the base-frame, and an endless rope running over said pulleys and that on the carriage; with a longitudinal screw-shaft in the frame, a traveling nut thereon, a slidable connection between said nut and the carriage, and means for rotating said screw; and rotatable cutters adapted to operate upon the object mounted on the carriage as it moves therepast.

25. In a woodworking-machine, the combination of a fixed cutting-tool, a traveling carriage adapted to hold the wood to be worked, means for rotating said wood in said carriage, an adjustable track for said carriage, and adjustable legs supporting each end of said carriage upon said track whereby the position of the object on the carriage may be varied.

26. In a woodworking-machine, the combination of a longitudinally-movable carriage rotatably carrying the article to be turned, a longitudinally-adjustable knife-holder secured to said carriage, a knife slidably mounted thereon, a spring adapted to withdraw said knife from the article to be turned, a flat spring secured to said carriage and adapted to engage said knife and an adjustable stationary arm adapted to press forward said flat spring and said knife as said carriage travels.

27. In a woodworking-machine, the combination of a cutting-tool, a pattern-track, a carriage adapted to hold the work mounted on said track, means for adjusting the carriage upon the track to vary the position of the work relatively to the cutting-tool, and means for rotating the work as it is moved past the cutting-tool.

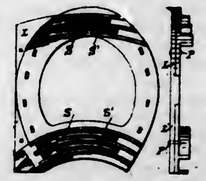
28. In a woodworking-machine, the combination of a fixed cutting-tool, a pattern-track, a work-supporting carriage mounted on said track, means for adjusting the ends of the carriage relatively to the track so as to vary the position of the work relatively to the tool; means for moving the carriage on the track, and means for rotating the work on the carriage as the latter travels.

29. In combination, a base, a horizontally-disposed pattern-track thereon, a horizontally-disposed carriage moving upon said track, rotatable face-plates on said carriage adapted to support the object to be operated upon, a pulley mounted on the carriage, gearing between the pulley and one of the face-plates, pulleys at opposite ends of the frame, and an endless belt or rope running over said pulleys to impart rotation to the object as the carriage travels, and a cutter beside the path of the carriage adapted to operate on the object as it moves therepast, substantially as described.

30. In a woodworking-machine, the combination of a fixed cutting-tool, a pattern-track, a carriage adapted to hold the object to be worked, mounted on said track, means for moving the carriage on the track, and means for rotating the work on the carriage as it travels; with means mounted on and traveling with the carriage for annularly grooving the object, substantially as set forth

31. In a machine for making columns, the combination of a pattern-track, a carriage movable thereon; heads on the carriage for supporting the column, means for moving the carriage on the track, and means for rotating the column as it travels; with a cutter beside the track of the carriage adapted to operate on the column as it moves therepast, and a cutter mounted on the carriage adapted to groove the column while it travels, substantially as described.

809,553. **HORSESHOE.** CHARLES A. CAMPBELL and JAMES REAGAN, Philadelphia, Pa. Filed Jan. 16, 1905. Serial No. 241,193.



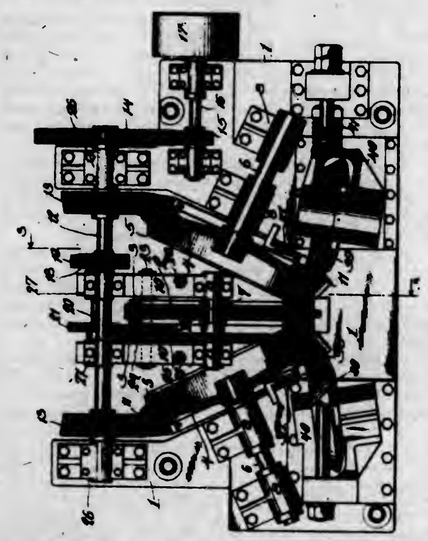
Claim.—1. A horseshoe provided on the lower face, at the toe and heel, with a series of curved calks extending entirely across the shoe from side to side, and spaced to allow channels or grooves therebetween the grooves or channels being made narrower, in cross-section, at the bottom than at the top, to permit sand or dirt to enter the decreased entrance and become packed within the same,

and to leave more of the roughened surface exposed as the calks wear away, substantially as specified.

2. In a horseshoe provided on the edge at the toe and heel, with projections extending laterally, in combination with grooves and channels and interlocking spurs and further secured to the shoe by means of rivets, substantially as shown and described.

3. A horseshoe provided with curved calks or cleats forming grooves or channels between said calks, and a series of elongated slots made through the body of the shoe at the bottom of each groove, to retain dirt, sand or grit, to prevent slipping, substantially as shown and set forth.

809,554. MACHINE FOR MOLDING ARTICLES FROM PLASTIC MATERIALS. HENRY W. H. COLE, Brooklyn, N. Y., assignor to The Briquetting Company, New York, N. Y., a Corporation of New Jersey. Filed Apr. 30, 1904. Serial No. 206,657.



Claim.—1. In a machine of the class described, the combination with an intermediate mold-wheel having oppositely-disposed independent lateral mold-recesses, of two mold-wheels arranged upon opposite sides of said intermediate wheel, and having lateral mold-recesses in register with the respective mold-recesses of the said intermediate mold-wheel, and means for driving the said mold-wheels and retaining their respective mold-recesses in register.

2. In a machine of the class described, the combination with an intermediate mold-wheel having two oppositely-disposed lateral molding-faces, of two mold-wheels arranged upon opposite sides of said intermediate wheel, and having lateral molding-faces in register with the molding-faces of the said intermediate mold-wheel, and means for driving the said mold-wheels, including gear-wheels for engaging the peripheries of the two said outer mold-wheels.

3. In a machine of the class described, the combination with an intermediate mold-wheel having two oppositely-disposed lateral molding-faces, of two mold-wheels arranged upon opposite sides of said intermediate wheel, and having lateral molding-faces in register with the molding-faces of the said intermediate mold-wheel, yielding pressure-rolls engaging the outer mold-wheels opposite the pressure-point, and means for driving the said mold-wheels.

4. In a machine of the class described, the combination with an intermediate mold-wheel having two oppositely-disposed lateral molding-faces, of two mold-wheels arranged upon opposite sides of said intermediate wheel, and having lateral molding-faces in register with the mold-faces of the said intermediate mold-wheel, said outer mold-wheels arranged to slide longitudinally in their bearings, spring pressure-rolls engaging said mold-wheels opposite the pressure-point and resisting said longitudinal movement, and means for driving said mold-wheels.

5. In a machine of the class described, the combination with a plurality of mold-wheels having lateral molding-faces in register with each other, and shafts upon which said mold-wheels are mounted, the axes of rotation of said wheels arranged obliquely to each other, of bearings rotatably supporting the shafts of said mold-wheels and permitting limited longitudinal movement thereof, spring pressure-rolls engaging said mold-wheels, substantially opposite the pressure-point, and means for driving the said mold-wheels.

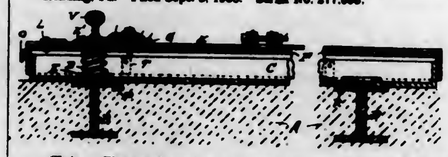
6. In a machine of the class described, the combination with a plurality of mold-wheels having lateral molding-faces in register with each other, the axes of rotation of said wheels arranged obliquely to each other, said wheels having outwardly-projecting peripheral teeth, of driving-wheels therefor engaging said peripheral teeth, and a single shaft upon which both said driving-wheels are mounted.

7. A machine for the purpose specified, having an intermediate mold-wheel with two lateral molding-faces, each lying in a plane at right angles to the axis of the wheel, two similar oblique mold-wheels situated at the respective opposite sides of said intermediate wheel, each of said oblique wheels having a conical, bevel molding-face in tangential contact with a lateral face on said intermediate wheel, the molds, and means for rotating said mold-wheels.

8. A machine for the purpose specified, having oblique mold-wheels 4 and an intermediate mold-wheel 2, said wheels carrying recessed molds in their molding-faces and having in each mold-recess an automatic ejector for the briquets.

9. A machine for the purpose specified having two oblique mold-wheels, and an intermediate mold-wheel, said wheels carrying recessed molds in their molding-faces, and having also means for driving said wheels in unison from their peripheries and means for pressing together their molding-faces.

809,555. RAIL AND TIE FASTENER. ALFRED S. DERIEMER, Reading, Pa. Filed Sept. 5, 1905. Serial No. 277,088.



Claim.—The combination of a railway-tie comprising an approximately rectangular box, a cover capable of vertical movement, springs interposed between the vertical walls of said box and cover, a cup-like receptacle formed in the base of said box near either end, a coiled spring located in each of said receptacles, a clamping device formed of two plates, one of which is permanently secured to the tie and the other movably secured to the top of said permanent plate, said plates having serrated meeting faces, bars passing under said clamping-plates and under the rail and formed with a hook at their outer ends adapted to engage the base of the rail and lugs formed on their inner ends, a bolt passing through the lugs on the two oppositely-disposed bars and adapted to draw them together, with metal I-shaped beams on which the ties rest and to which they are removably secured, and a bed of concrete in which said beams are completely embedded, leaving only their upper surfaces exposed.

809,556. DIAL-LOCK. LOUIS A. DEUBEL, Chicago, Ill. Filed Oct. 27, 1904. Serial No. 230,188.

Claim.—1. In a dial-lock, the combination with a dial-carrying plate, of rotary dials disposed upon the plate and having stems passing through the plate and provided with lugs, separable elements having slots adapted for the passage of the said stems and lugs whereby said elements are locked together, the said plate having hinge-plates at each end, and one of said hinge-plates being secured to one of said separable elements, and means arranged to cover the edges of both hinge-plates when said dial-carrying plate is in locked position.

2. In a dial-lock, the combination with a dial-carrying plate, of rotary dials disposed upon the plate and having stems passing through the plate and provided with lugs, separable elements having slots adapted for the passage of the said stems and lugs whereby said elements are locked together, the said plate having inwardly-extending hinge-plates at each end, and one of said hinge-plates being secured to one of said separable elements, the said dial-carrying plates having aprons arranged, when said plate is in locked position, to cover the edges of both hinge-plates.

809,557. LOOSE-LEAF BINDER. ERNEST G. DUMAS, Lowell, Mass. Filed Sept. 11, 1905. Serial No. 277,886.

Claim.—1. In a loose-leaf binder, a lower cover comprising a binder member, posts arising from the lower binder member, an upper cover comprising a binder member, a recess in the upper binder member, a plate secured in the recess, orifices in the upper binder member and in the plate for the passage of said posts, fixed jaws, and levers forming clamps therewith about the posts, springs at the ends of the levers, set-screws bearing against the levers, and depressions in the upper binder member to receive the set-screws.

2. In a loose-leaf binder, a plate, a fixed clamp-jaw, a pivoted clamp-jaw cooperating therewith, a spring carried by the lever, and a set-screw adapted to operate the lever, combined with a binder member recessed for the plate with depressions for the set-screws, and orifices for the posts, a lower binder member, and posts rising therefrom as described.

3. In a loose-leaf binder, a lower cover, and posts rising therefrom, combined with an upper cover including a clamp-plate with orifices for the posts, clamp-jaws fixed thereto, clamp-jaws pivoted thereto, set-screws, and half-elliptic springs adapted to operate the pivoted jaws, rubber caps for the posts, and a binder member recessed for the plate, cut away for the set-screws and pierced for the posts as described.

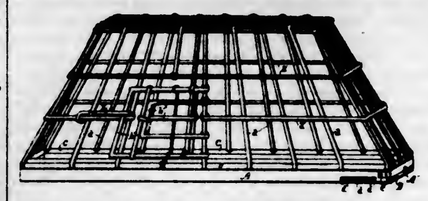
4. In a loose-leaf binder, an upper binder member and a lower binder member; posts arising from the lower binder member; openings in said upper binder member through which said posts pass; and means contained in the upper binder member for clamping said binder members comprising for each post, a fixed jaw, a lever-jaw pivoted at one end near said post, a half-elliptic spring carried by the other end of the pivoted jaw, a set-screw bearing against the free end of the pivoted jaw in opposition to the half-elliptic spring, and a depression in the upper binder member to receive said set-screw.

5. In a loose-leaf binder; a lower binder member; a plurality of posts arising therefrom; a complementary upper binder member comprising a recess for a plate, openings for the passage of the posts, and depressions for set-screws; combined with a plate fitted into the recess, a plurality of fixed jaws arranged to adjoin said openings and to conform to the surface of the posts, a plurality of lever-jaws pivoted at one end near said openings and shaped to conform to the surface of the posts and with an elongated free arm, a plurality of half-elliptic springs one centrally carried by the end of the long arm of each pivoted jaw whereby its ends bear against the side of the recess, a plurality of set-screws carried by said plate and adapted to bear against the side of the long arm of the pivoted jaw opposite to the half-elliptic springs; and rubber caps for said posts as described.

809,558. POULTRY-SHIPPING COOP. FRANK M. GAULT, Oklahoma, Okla. Filed Sept. 2, 1904. Serial No. 223,266.

Claim.—As an article of manufacture, a rectangular, inclosed shipping-coop A, comprising a floor *c*, sills *a* and *a'*, supporting the floor, vertical rods *e* inserted into the sills *a* and *a'*, by right-angled projections, for side and end walls, and bent at their upper ends to form a roof G, having a central opening B, a door D, provided with a fastening device E, substantially as described.

809,559. CRATE FOR TRANSPORTING POULTRY. FRANK M. GAULT, Oklahoma, Okla. Filed Apr. 5, 1905. Serial No. 253,963.

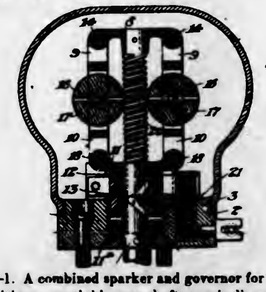


Claim.—1. A crate for transporting poultry, comprising an upper part or cage, formed of upwardly and inwardly inclined wire loops, having their feet removably secured in the sills, and a divisional and sectional base, whereby the respective parts may be detached, collected and shipped in separate packages, substantially as described.

2. In a crate for transporting poultry, the combination with a divisional and sectional base, comprising the detachable sills A A', the removable floor-pieces B, provided with staples *h h*, of an inwardly-tapering cage formed of wire loops *a* encircled with rib-wires *a'* and provided with a suitable door substantially as described.

3. In a transportation poultry-coop consisting of a tapering cage portion, its base being secured to sills providing a supporting-seat for the sliding removable bottom; the locking-pins *d' d'* secured in the ends of the longitudinal springs *d*, the said springs being firmly secured to the outer surface of the side sills, substantially as described and for the purposes set forth.

809,560. COMBINED SPARKER AND GOVERNOR FOR GAS-ENGINES. DAVID F. GRAHAM and FRANK A. FOX, Stamford, Conn., assignors, by mesne assignments, to The Bissbuth Horseless Vehicle Company, Middletown, Conn., a Corporation of Maine. Filed Mar. 11, 1903. Serial No. 147,239.



Claim.—1. A combined sparker and governor for explosive-engines, comprising a revoluble cam-shaft; a spirally-grooved sleeve mounted upon said shaft; a cam surrounding said sleeve and provided with projections entering the grooves of the sleeve and having an internally-threaded recess at its upper end; ignition-contacts operated by said cam; and a governor comprising an upper head fixed to said shaft, a lower movable head having an externally-threaded extension engaging the threaded recess in the cam and screwed partially home, toggle-levers connecting said heads, and weights on said levers, whereby the cam is given both a reciprocatory and a rotary movement, substantially as set forth.

2. A combined sparker and governor for explosive-engines, comprising a revoluble cam-shaft, a sleeve mounted upon said shaft and having oppositely-located exterior spiral grooves, a cam surrounding said sleeve and provided with interiorly-projecting pins entering said grooves, ignition-contacts operated by said cam, a movable governor-head connected to said cam by a threaded connection screwed partially home, a stationary governor-head carried by said shaft, and a centrifugally-acting connection between the two heads, for the purpose set forth.

3. A combined sparker and governor for explosive-engines, comprising a revoluble cam-shaft, a sleeve mounted upon said shaft

and having exterior spiral grooves, a cam surrounding said sleeve and provided with interiorly-projecting pins entering said grooves, ignition-contacts operated by said cam, a movable governor-head connected to said cam by a threaded connection screwed partially home, a stationary governor-head secured on said shaft, weighted toggle-arms connecting the two heads, and a coil-spring on said shaft tending to move the movable governor-head away from the stationary governor-head, whereby the cam is given both a reciprocatory and a rotary movement on said shaft, substantially as set forth.

4. A combined sparker and governor for explosive-engines, comprising a base, contact-springs secured to said base, ignition-contacts for said springs, contact-rollers carried by said springs, a revoluble cam-shaft extending through said base, a stationary governor-head carried by said shaft, a spirally-grooved sleeve mounted on said shaft, a cam surrounding said sleeve between said contact-springs and having projections entering the grooves of the sleeve, a movable governor-head connected to said cam by a threaded connection screwed partially home, and pivotal connections between said governor-heads, for the purpose set forth.

5. A combined sparker and governor for explosive-engines, comprising a revoluble cam-shaft, a spirally-grooved sleeve mounted on said shaft, a cam surrounding said sleeve and provided with pins entering the grooves of the sleeve and also provided with diametrically opposite cam-surfaces, a contact-spring on each side of said cam, rollers carried by said springs, contacts for the free ends of said springs, and a movable governor-head connected to said cam by a threaded connection screwed partially home, whereby said cam will be advanced and rotated to spread said springs apart and against their contacts, substantially as set forth.

809,561. **MECHANISM FOR CONSTRUCTING FLEXIBLE METAL TUBES AND ARMORING FLEXIBLE HOSE OR OTHER TUBES.** EDWIN T. GREENFIELD, Monticello, N. Y. Filed Dec. 3, 1904. Serial No. 235,309.

Claim.—1. A machine for forming flexible metal tubes or armoring flexible tubes, such as hose, with spirally-wound strips of metal, embracing means for forming a strengthening corrugation or bead in the direction of the length of the strips, and additional means for giving to said strips spiral tubular conformation.

2. A machine for forming flexible tubes from strips of metal embracing means for giving to said strips strengthening corrugations or beads in the direction of their length; in combination with means for giving them spiral tubular conformation, and additional means for guiding the strips from the first-named means to and through the latter.

3. A machine for forming flexible tubes from strips of metal, embracing means for giving to said strips a concave or convex cross-section and simultaneously producing a longitudinal strengthening corrugation or bead therein; in combination with additional means for giving to said strips spiral tubular conformation.

4. A machine for forming flexible tubes from a strip of metal, embracing means for simultaneously giving to said strip a concave or a convex cross-section and a longitudinal strengthening corrugation or bead; in combination with means for forming the same into successive tubular spirals and additional means for guiding the strip or strips continuously to the tube-forming means.

5. A machine for forming flexible tubes from strips of metal, embracing means for giving to two such strips respectively convex and concave cross-sections and an additional longitudinal strengthening corrugation or bead in each; in combination with means for causing said strips to assume a conjoint spiral relation such that the concave and convex spirals interlock.

6. In a machine for forming tubes from strips of metal a screw-threaded forming-die; in combination with a housing or guideway for giving to the strip an initial tubular conformation on entering the die, and additional means for forcing the strip endwise through the guideway and the die.

7. In a machine for forming tubes from a strip of metal a forming-die screw-threaded interiorly at such pitch as will give the desired spiral convolutions to the strip; in combination with a housing or guideway adapted with the die to give to the strip an initial tubular and spiral conformation; together with means for forcing the strip endwise through the guideway and the screw-threaded die.

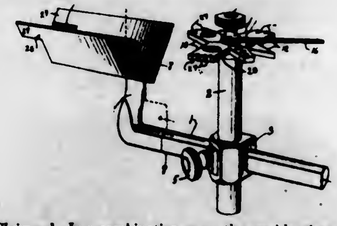
8. In a machine for forming tubes from a strip of metal, means for giving to the strip a convex or concave cross-section and for simultaneously advancing or feeding the same forward; in combination with a forming-die screw-threaded interiorly with threads which conform in cross-section with the convex or concave formation of the strip; together with a housing or guideway located concentric with the first thread of the die and adapted to give to the strip its initial tubular and spiral conformation.

9. In a machine for forming tubes from strips of metal, means for advancing or feeding the same forward endwise; in combination with a forming-die screw-threaded internally with threads which conform to the shape and width of the strip and a housing or guideway concentric with the first thread of the die for giving to the strip as it is forced into the die its initial curvature and spiral convolution.

10. A forming-die screw-threaded internally and provided with a side opening coinciding with one of the threads thereof; in combination with a curvilinear guideway substantially concentric with said thread for giving to a strip of metal when forced into the die an initial curvature and spiral conformation.

11. In a machine for forming tubes from strips of metal a die screw-threaded internally and provided with a side opening coinciding with one of the threads thereof; in combination with a curvilinear guideway substantially concentric with said thread; together with additional means for forcing a strip of metal through the side opening between the thread and the concentric means and successively through the remaining threads of the die.

809,562. **COMBINATION-GAGE.** FREDERICK GUMPF, Massillon, Ohio. Filed Aug. 14, 1905. Serial No. 274,188.



Claim.—1. In a combination-gage, the combination of bars located at right angles to each other and adjustable with reference to each other, one of said bars provided with a tool-holding trough, and the other bar provided with a gage-disk, and means for holding the gage-disk in fixed adjustment, and means for holding the adjustable bars in fixed adjustment, substantially as and for the purpose specified.

2. In a combination-gage, the combination of bars located at right angles to each other and adjustable with reference to each other, one of said bars provided with a trough, and the other bar provided with a gage-disk, said gage-disk provided with angled edges of different angularities, and means for holding the gage-disk in fixed adjustment, and means for holding the bars in fixed adjustment, substantially as and for the purpose specified.

3. In a combination-gage, the combination of bars located at an angle one to the other, one of said bars provided with a gage-disk and the other with a trough, said gage-disk provided with angled edges having different angularities, apertures formed in the gage-disk of different diameters, and said gage-disk provided with screw-pitch notches, and means for holding the adjustable bars in fixed adjustment, substantially as and for the purpose specified.

4. In a combination-gage, the combination of adjustable bars located at an angle one to the other, one of said bars provided with a gage-disk, said gage-disk provided with varying reëntrant angles, said gage-disk provided with screw-pitch notches and means for holding the adjustable bars in fixed adjustment, and a trough carried by the other of the adjustable bars, substantially as and for the purpose specified.

5. In a combination-gage, the combination of adjustable bars, means for holding the adjustable bars in fixed adjustment, one of said bars provided with a gage-disk having edges of different angularities, a center-rule rotatable concentrically with the gage-disk, means for holding said center-rule in fixed relation with the gage-disk, and means for holding the gage-disk, and center-rule against rotation, and a trough carried by the other of the adjustable bars, substantially as and for the purpose specified.

6. In a combination-gage, the combination of adjustable bars, one of said bars provided with a gage-disk, said gage-disk rotatably mounted upon its bar, and a trough carried by the other adjustable bar, said trough provided with a cut-out portion, substantially as and for the purpose specified.

809,563. **VENDING-MACHINE.** HANS K. HANSEN, Sioux City, Iowa. Filed Mar. 16, 1905. Serial No. 250,448.

Claim.—1. In a vending-machine, the combination with a reservoir, of a pair of delivery-plates having article-engaging surfaces extending, respectively, in opposite directions, said plates being arranged one above the other and spaced for a distance approximately equal to the diameter of the articles in the magazine, a pinion connected to the plates, a rack-bar engaging said pinion, and means for operating said rack-bar.

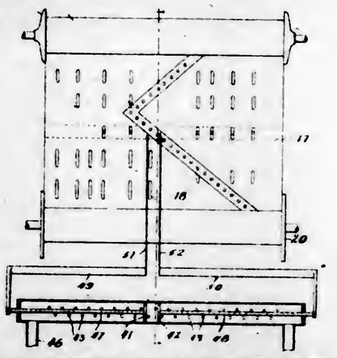
2. In a vending-machine, the combination with a reservoir, of a pair of delivery-plates having article-engaging surfaces extending, respectively, in opposite directions, and spaced vertically from each other for a distance approximately equal to the diameter of the articles in the magazine, a pinion arranged between the plates, a rack-bar intermeshing with the pinion, means for moving said rack-bar in one direction, means for automatically locking said rack-bar at the limit of its inward movement, an operating-rod, and means controllable by the operating-rod for releasing said rack-bar.

3. In a vending-machine, the combination with a reservoir, of a plurality of sets of delivery-plates, each set being formed of two superposed plates having article-engaging surfaces extending, respectively, in opposite directions, a pinion arranged between said plates, a slidable rack-bar having teeth intermeshing with the pinions, an operating-rod for effecting inward movement of the rack-bar, a pawl for locking the rack-bar at the limit of its inward movement, a spring for restoring the rack-bar to its initial position, and means carried by the operating-rod for engaging and moving said pawl to release position.

809,564. **SHUTTLE FOR RIBBON-LOOMS.** WILHELM HAUSMANN, Barmen, Germany. Filed Apr. 21, 1905. Serial No. 256,602.

Claim.—In a shuttle for looms, the shuttle-body provided with a thread-guide G fixed rigidly to the body of the shuttle behind the bobbin B and of parabolic shape in its longitudinal direction and also in transverse direction on the rear part of the same, the whole as described and illustrated and for the purpose set forth.

809,565. **SELF-PLAYING MECHANISM FOR INSTRUMENTS.** FREDERICK W. HEDGLAND, Chicago, Ill. Filed July 21, 1905. Serial No. 270,605.



Claim.—1. In a self-playing organ, the combination with a solo-manual and an accompaniment-manual, of a music-sheet controlling both manuals and employing the same perforations for both, means whereby the sheet causes the operation of both manuals, and means whereby the operator may silence the notes of the solo-manual not embraced in the solo, such means consisting of the plungers and the cylinder containing the plungers and having perforations connected to the action of the solo-manual.

2. The combination with an instrument having no less than two manuals, of a perforated music-sheet controlling the manuals, and means under the control of the operator whereby he may silence all the notes except the solo-notes upon one manual without interfering with the accompaniment upon the other manual.

3. In an automatic musical instrument, the combination of a solo-manual, an accompaniment-manual, means for playing both manuals automatically and means under the control of the operator for silencing at will such notes as he may desire on the solo-manual while permitting the playing of the notes of the accompaniment upon the other manual.

4. The combination with the automatic playing mechanism embodying a perforated music-sheet, of a two-manual organ, embodying a solo-manual and an accompaniment-manual, both manuals being controlled by the same perforations in the music-sheet, of means whereby the operator selects such of the notes upon the sheet as he wishes to play upon the solo-organ and silences the others upon the same organ.

5. The combination with the automatic playing mechanism of a two-manual organ or similar instrument employing a perforated music-sheet, of means whereby the operator may select and permit the notes of a solo to be played together with an accompaniment, while he prevents the sounding by the solo register of the notes occurring in the music-sheet other than those of the solo.

6. The combination with the solo-manual, the accompaniment-manual, the music-sheet and means whereby the sheet controls both

manuals, of means for normally silencing all the notes of the solo-manual, and means for selecting such of the notes of the solo-manual as are to be played with the accompaniment, substantially as set forth.

7. The combination with the automatic playing mechanism embodying a perforated music-sheet, of a two-manual organ, embodying a solo-manual and an accompaniment-manual, both manuals being controlled by the same perforations in the music-sheet, of means whereby the operator selects such of the notes upon the sheet as he wishes to play upon the solo-organ and silences the others upon the same organ, and means whereby the operator may silence the notes of the solo-manual not embraced in the solo, such means consisting of the plungers and the cylinder containing the plungers and having perforations connected to the action of the solo-manual.

8. The combination with the automatic playing mechanism embodying a perforated music-sheet, of a two-manual organ, embodying a solo-manual and an accompaniment-manual, both manuals being controlled by the same perforations in the music-sheet, of means whereby the operator selects such of the notes upon the sheet as he wishes to play upon the solo-organ and silences the others upon the same organ, means whereby the operator may silence the notes of the solo-manual not embraced in the solo, such means consisting of the plungers and the cylinder containing the plungers and having perforations connected to the action of the solo-manual, and means whereby the operator may select and permit the notes of a solo to be played together with an accompaniment, while he prevents the sounding by the solo register of the notes occurring in the music-sheet other than those of the solo.

9. The combination with the automatic playing mechanism embodying a perforated music-sheet, of a two-manual organ, embodying a solo-manual and an accompaniment-manual, both manuals being controlled by the same perforations in the music-sheet, of means whereby the operator selects such of the notes upon the sheet as he wishes to play upon the solo-organ and silences the others upon the same organ, means whereby the operator may silence the notes of the solo-manual not embraced in the solo, such means consisting of the plungers and the cylinder containing the plungers and having perforations connected to the action of the solo-manual, means whereby the operator may select and permit the notes of a solo to be played together with an accompaniment, while he prevents the sounding by the solo register of the notes occurring in the music-sheet other than those of the solo, and means whereby the sheet controls both manuals and the operation of the plungers.

10. The combination with the automatic playing mechanism embodying a perforated music-sheet, of a two-manual organ, embodying a solo-manual and an accompaniment-manual, both manuals being controlled by the same perforations in the music-sheet, of means whereby the operator selects such of the notes upon the sheet as he wishes to play upon the solo-organ and silences the others upon the same organ, means whereby the operator may silence the notes of the solo-manual not embraced in the solo, such means consisting of the plungers and the cylinder containing the plungers and having perforations connected to the action of the solo-manual, means whereby the operator may select and permit the notes of a solo to be played together with an accompaniment, while he prevents the sounding by the solo register of the notes occurring in the music-sheet other than those of the solo, means whereby the sheet controls both manuals and the operation of the plungers, and means whereby the sheet controls the operation of the solo-register.

11. The combination with the automatic playing mechanism embodying a perforated music-sheet, of a two-manual organ, embodying a solo-manual and an accompaniment-manual, both manuals being controlled by the same perforations in the music-sheet, of means whereby the operator selects such of the notes upon the sheet as he wishes to play upon the solo-organ and silences the others upon the same organ, means whereby the operator may silence the notes of the solo-manual not embraced in the solo, such means consisting of the plungers and the cylinder containing the plungers and having perforations connected to the action of the solo-manual, means whereby the operator may select and permit the notes of a solo to be played together with an accompaniment, while he prevents the sounding by the solo register of the notes occurring in the music-sheet other than those of the solo, means whereby the sheet controls both manuals and the operation of the plungers, means whereby the sheet controls the operation of the solo-register, and means whereby the operator may silence the accompaniment-manual.

12. The combination with the automatic playing mechanism embodying a perforated music-sheet, of a two-manual organ, embodying a solo-manual and an accompaniment-manual, both manuals being controlled by the same perforations in the music-sheet, of means whereby the operator selects such of the notes upon the sheet as he wishes to play upon the solo-organ and silences the others upon the same organ, means whereby the operator may silence the notes of the solo-manual not embraced in the solo, such means consisting of the plungers and the cylinder containing the plungers and having perforations connected to the action of the solo-manual, means whereby the operator may select and permit the notes of a solo to be played together with an accompaniment, while he prevents the sounding by the solo register of the notes occurring in the music-sheet other than those of the solo, means whereby the sheet controls both manuals and the operation of the plungers, means whereby the sheet controls the operation of the solo-register, means whereby the operator may silence the accompaniment-manual, and means whereby the sheet controls the operation of the accompaniment-manual.

13. The combination with the automatic playing mechanism embodying a perforated music-sheet, of a two-manual organ, embodying a solo-manual and an accompaniment-manual, both manuals being controlled by the same perforations in the music-sheet, of means whereby the operator selects such of the notes upon the sheet as he wishes to play upon the solo-organ and silences the others upon the same organ, means whereby the operator may silence the notes of the solo-manual not embraced in the solo, such means consisting of the plungers and the cylinder containing the plungers and having perforations connected to the action of the solo-manual, means whereby the operator may select and permit the notes of a solo to be played together with an accompaniment, while he prevents the sounding by the solo register of the notes occurring in the music-sheet other than those of the solo, means whereby the sheet controls both manuals and the operation of the plungers, means whereby the sheet controls the operation of the solo-register, means whereby the operator may silence the accompaniment-manual, means whereby the sheet controls the operation of the accompaniment-manual, and means whereby the operator may silence the solo-register.

14. The combination with the automatic playing mechanism embodying a perforated music-sheet, of a two-manual organ, embodying a solo-manual and an accompaniment-manual, both manuals being controlled by the same perforations in the music-sheet, of means whereby the operator selects such of the notes upon the sheet as he wishes to play upon the solo-organ and silences the others upon the same organ, means whereby the operator may silence the notes of the solo-manual not embraced in the solo, such means consisting of the plungers and the cylinder containing the plungers and having perforations connected to the action of the solo-manual, means whereby the operator may select and permit the notes of a solo to be played together with an accompaniment, while he prevents the sounding by the solo register of the notes occurring in the music-sheet other than those of the solo, means whereby the sheet controls both manuals and the operation of the plungers, means whereby the sheet controls the operation of the solo-register, means whereby the operator may silence the accompaniment-manual, means whereby the sheet controls the operation of the accompaniment-manual, means whereby the operator may silence the solo-register, and means whereby the sheet controls the operation of the solo-register.

15. The combination with the automatic playing mechanism embodying a perforated music-sheet, of a two-manual organ, embodying a solo-manual and an accompaniment-manual, both manuals being controlled by the same perforations in the music-sheet, of means whereby the operator selects such of the notes upon the sheet as he wishes to play upon the solo-organ and silences the others upon the same organ, means whereby the operator may silence the notes of the solo-manual not embraced in the solo, such means consisting of the plungers and the cylinder containing the plungers and having perforations connected to the action of the solo-manual, means whereby the operator may select and permit the notes of a solo to be played together with an accompaniment, while he prevents the sounding by the solo register of the notes occurring in the music-sheet other than those of the solo, means whereby the sheet controls both manuals and the operation of the plungers, means whereby the sheet controls the operation of the solo-register, means whereby the operator may silence the accompaniment-manual, means whereby the sheet controls the operation of the accompaniment-manual, means whereby the operator may silence the solo-register, means whereby the sheet controls the operation of the solo-register, and means whereby the operator may silence the accompaniment-manual.

16. The combination with the automatic playing mechanism embodying a perforated music-sheet, of a two-manual organ, embodying a solo-manual and an accompaniment-manual, both manuals being controlled by the same perforations in the music-sheet, of means whereby the operator selects such of the notes upon the sheet as he wishes to play upon the solo-organ and silences the others upon the same organ, means whereby the operator may silence the notes of the solo-manual not embraced in the solo, such means consisting of the plungers and the cylinder containing the plungers and having perforations connected to the action of the solo-manual, means whereby the operator may select and permit the notes of a solo to be played together with an accompaniment, while he prevents the sounding by the solo register of the notes occurring in the music-sheet other than those of the solo, means whereby the sheet controls both manuals and the operation of the plungers, means whereby the sheet controls the operation of the solo-register, means whereby the operator may silence the accompaniment-manual, means whereby the sheet controls the operation of the accompaniment-manual, means whereby the operator may silence the solo-register, means whereby the sheet controls the operation of the solo-register, means whereby the operator may silence the accompaniment-manual, and means whereby the sheet controls the operation of the accompaniment-manual.

17. The combination with the automatic playing mechanism embodying a perforated music-sheet, of a two-manual organ, embodying a solo-manual and an accompaniment-manual, both manuals being controlled by the same perforations in the music-sheet, of means whereby the operator selects such of the notes upon the sheet as he wishes to play upon the solo-organ and silences the others upon the same organ, means whereby the operator may silence the notes of the solo-manual not embraced in the solo, such means consisting of the plungers and the cylinder containing the plungers and having perforations connected to the action of the solo-manual, means whereby the operator may select and permit the notes of a solo to be played together with an accompaniment, while he prevents the sounding by the solo register of the notes occurring in the music-sheet other than those of the solo, means whereby the sheet controls both manuals and the operation of the plungers, means whereby the sheet controls the operation of the solo-register, means whereby the operator may silence the accompaniment-manual, means whereby the sheet controls the operation of the accompaniment-manual, means whereby the operator may silence the solo-register, means whereby the sheet controls the operation of the solo-register, means whereby the operator may silence the accompaniment-manual, means whereby the sheet controls the operation of the accompaniment-manual, and means whereby the operator may silence the solo-register.

18. The combination with the automatic playing mechanism embodying a perforated music-sheet, of a two-manual organ, embodying a solo-manual and an accompaniment-manual, both manuals being controlled by the same perforations in the music-sheet, of means whereby the operator selects such of the notes upon the sheet as he wishes to play upon the solo-organ and silences the others upon the same organ, means whereby the operator may silence the notes of the solo-manual not embraced in the solo, such means consisting of the plungers and the cylinder containing the plungers and having perforations connected to the action of the solo-manual, means whereby the operator may select and permit the notes of a solo to be played together with an accompaniment, while he prevents the sounding by the solo register of the notes occurring in the music-sheet other than those of the solo, means whereby the sheet controls both manuals and the operation of the plungers, means whereby the sheet controls the operation of the solo-register, means whereby the operator may silence the accompaniment-manual, means whereby the sheet controls the operation of the accompaniment-manual, means whereby the operator may silence the solo-register, means whereby the sheet controls the operation of the solo-register, means whereby the operator may silence the accompaniment-manual, means whereby the sheet controls the operation of the accompaniment-manual, means whereby the operator may silence the solo-register, and means whereby the sheet controls the operation of the solo-register.

19. The combination with the automatic playing mechanism embodying a perforated music-sheet, of a two-manual organ, embodying a solo-manual and an accompaniment-manual, both manuals being controlled by the same perforations in the music-sheet, of means whereby the operator selects such of the notes upon the sheet as he wishes to play upon the solo-organ and silences the others upon the same organ, means whereby the operator may silence the notes of the solo-manual not embraced in the solo, such means consisting of the plungers and the cylinder containing the plungers and having perforations connected to the action of the solo-manual, means whereby the operator may select and permit the notes of a solo to be played together with an accompaniment, while he prevents the sounding by the solo register of the notes occurring in the music-sheet other than those of the solo, means whereby the sheet controls both manuals and the operation of the plungers, means whereby the sheet controls the operation of the solo-register, means whereby the operator may silence the accompaniment-manual, means whereby the sheet controls the operation of the accompaniment-manual, means whereby the operator may silence the solo-register, means whereby the sheet controls the operation of the solo-register, means whereby the operator may silence the accompaniment-manual, means whereby the sheet controls the operation of the accompaniment-manual, means whereby the operator may silence the solo-register, means whereby the sheet controls the operation of the solo-register, and means whereby the operator may silence the accompaniment-manual.

20. The combination with the automatic playing mechanism embodying a perforated music-sheet, of a two-manual organ, embodying a solo-manual and an accompaniment-manual, both manuals being controlled by the same perforations in the music-sheet, of means whereby the operator selects such of the notes upon the sheet as he wishes to play upon the solo-organ and silences the others upon the same organ, means whereby the operator may silence the notes of the solo-manual not embraced in the solo, such means consisting of the plungers and the cylinder containing the plungers and having perforations connected to the action of the solo-manual, means whereby the operator may select and permit the notes of a solo to be played together with an accompaniment, while he prevents the sounding by the solo register of the notes occurring in the music-sheet other than those of the solo, means whereby the sheet controls both manuals and the operation of the plungers, means whereby the sheet controls the operation of the solo-register, means whereby the operator may silence the accompaniment-manual, means whereby the sheet controls the operation of the accompaniment-manual, means whereby the operator may silence the solo-register, means whereby the sheet controls the operation of the solo-register, means whereby the operator may silence the accompaniment-manual, means whereby the sheet controls the operation of the accompaniment-manual, means whereby the operator may silence the solo-register, means whereby the sheet controls the operation of the solo-register, means whereby the operator may silence the accompaniment-manual, and means whereby the sheet controls the operation of the accompaniment-manual.

21. The combination with the automatic playing mechanism embodying a perforated music-sheet, of a two-manual organ, embodying a solo-manual and an accompaniment-manual, both manuals being controlled by the same perforations in the music-sheet, of means whereby the operator selects such of the notes upon the sheet as he wishes to play upon the solo-organ and silences the others upon the same organ, means whereby the operator may silence the notes of the solo-manual not embraced in the solo, such means consisting of the plungers and the cylinder containing the plungers and having perforations connected to the action of the solo-manual, means whereby the operator may select and permit the notes of a solo to be played together with an accompaniment, while he prevents the sounding by the solo register of the notes occurring in the music-sheet other than those of the solo, means whereby the sheet controls both manuals and the operation of the plungers, means whereby the sheet controls the operation of the solo-register, means whereby the operator may silence the accompaniment-manual, means whereby the sheet controls the operation of the accompaniment-manual, means whereby the operator may silence the solo-register, means whereby the sheet controls the operation of the solo-register, means whereby the operator may silence the accompaniment-manual, means whereby the sheet controls the operation of the accompaniment-manual, means whereby the operator may silence the solo-register, means whereby the sheet controls the operation of the solo-register, means whereby the operator may silence the accompaniment-manual, means whereby the sheet controls the operation of the accompaniment-manual, and means whereby the operator may silence the solo-register.

22. The combination with the automatic playing mechanism embodying a perforated music-sheet, of a two-manual organ, embodying a solo-manual and an accompaniment-manual, both manuals being controlled by the same perforations in the music-sheet, of means whereby the operator selects such of the notes upon the sheet as he wishes to play upon the solo-organ and silences the others upon the same organ, means whereby the operator may silence the notes of the solo-manual not embraced in the solo, such means consisting of the plungers and the cylinder containing the plungers and having perforations connected to the action of the solo-manual, means whereby the operator may select and permit the notes of a solo to be played together with an accompaniment, while he prevents the sounding by the solo register of the notes occurring in the music-sheet other than those of the solo, means whereby the sheet controls both manuals and the operation of the plungers, means whereby the sheet controls the operation of the solo-register, means whereby the operator may silence the accompaniment-manual, means whereby the sheet controls the operation of the accompaniment-manual, means whereby the operator may silence the solo-register, means whereby the sheet controls the operation of the solo-register, means whereby the operator may silence the accompaniment-manual, means whereby the sheet controls the operation of the accompaniment-manual, means whereby the operator may silence the solo-register, means whereby the sheet controls the operation of the solo-register, means whereby the operator may silence the accompaniment-manual, means whereby the sheet controls the operation of the accompaniment-manual, means whereby the operator may silence the solo-register, and means whereby the sheet controls the operation of the solo-register.

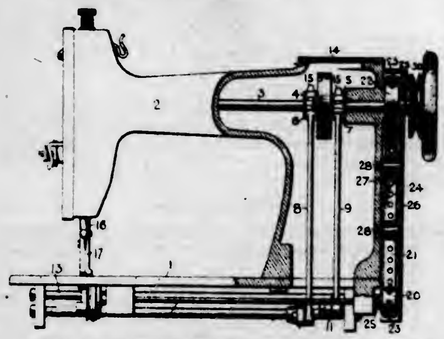
23. The combination with the automatic playing mechanism embodying a perforated music-sheet, of a two-manual organ, embodying a solo-manual and an accompaniment-manual, both manuals being controlled by the same perforations in the music-sheet, of means whereby the operator selects such of the notes upon the sheet as he wishes to play upon the solo-organ and silences the others upon the same organ, means whereby the operator may silence the notes of the solo-manual not embraced in the solo, such means consisting of the plungers and the cylinder containing the plungers and having perforations connected to the action of the solo-manual, means whereby the operator may select and permit the notes of a solo to be played together with an accompaniment, while he prevents the sounding by the solo register of the notes occurring in the music-sheet other than those of the solo, means whereby the sheet controls both manuals and the operation of the plungers, means whereby the sheet controls the operation of the solo-register, means whereby the operator may silence the accompaniment-manual, means whereby the sheet controls the operation of the accompaniment-manual, means whereby the operator may silence the solo-register, means whereby the sheet controls the operation of the solo-register, means whereby the operator may silence the accompaniment-manual, means whereby the sheet controls the operation of the accompaniment-manual, means whereby the operator may silence the solo-register, means whereby the sheet controls the operation of the solo-register, means whereby the operator may silence the accompaniment-manual, means whereby the sheet controls the operation of the accompaniment-manual, means whereby the operator may silence the solo-register, and means whereby the sheet controls the operation of the solo-register.

24. The combination with the automatic playing mechanism embodying a perforated music-sheet, of a two-manual organ, embodying a solo-manual and an accompaniment-manual, both manuals being controlled by the same perforations in the music-sheet, of means whereby the operator selects such of the notes upon the sheet as he wishes to play upon the solo-organ and silences the others upon the same organ, means whereby the operator may silence the notes of the solo-manual not embraced in the solo, such means consisting of the plungers and the cylinder containing the plungers and having perforations connected to the action of the solo-manual, means whereby the operator may select and permit the notes of a solo to be played together with an accompaniment, while he prevents the sounding by the solo register of the notes occurring in the music-sheet other than those of the solo, means whereby the sheet controls both manuals and the operation of the plungers, means whereby the sheet controls the operation of the solo-register, means whereby the operator may silence the accompaniment-manual, means whereby the sheet controls the operation of the accompaniment-manual, means whereby the operator may silence the solo-register, means whereby the sheet controls the operation of the solo-register, means whereby the operator may silence the accompaniment-manual, means whereby the sheet controls the operation of the accompaniment-manual, means whereby the operator may silence the solo-register, means whereby the sheet controls the operation of the solo-register, means whereby the operator may silence the accompaniment-manual, means whereby the sheet controls the operation of the accompaniment-manual, means whereby the operator may silence the solo-register, means whereby the sheet controls the operation of the solo-register, and means whereby the operator may silence the accompaniment-manual.

25. The combination with the automatic playing mechanism embodying a perforated music-sheet, of a two-manual organ, embodying a solo-manual and an accompaniment-manual, both manuals being controlled by the same perforations in the music-sheet, of means whereby the operator selects such of the notes upon the sheet as he wishes to play upon the solo-organ and silences the others upon the same organ, means whereby the operator may silence the notes of the solo-manual not embraced in the solo, such means consisting of the plungers and the cylinder containing the plungers and having perforations connected to the action of the solo-manual, means whereby the operator may select and permit the notes of a solo to be played together with an accompaniment, while he prevents the sounding by the solo register of the notes occurring in the music-sheet other than those of the solo, means whereby the sheet controls both manuals and the operation of the plungers, means whereby the sheet controls the operation of the solo-register, means whereby the operator may silence the accompaniment-manual, means whereby the sheet controls the operation of the accompaniment-manual, means whereby the operator may silence the solo-register, means whereby the sheet controls the operation of the solo-register, means whereby the operator may silence the accompaniment-manual, means whereby the sheet controls the operation of the accompaniment-manual, means whereby the operator may silence the solo-register, means whereby the sheet controls the operation of the solo-register, means whereby the operator may silence the accompaniment-manual, means whereby the sheet controls the operation of the accompaniment-manual, means whereby the operator may silence the solo-register, means whereby the sheet controls the operation of the solo-register, means whereby the operator may silence the accompaniment-manual, and means whereby the sheet controls the operation of the accompaniment-manual.

manuals, of means for normally silencing all the notes of the solo-manual, and means for selecting such of said notes as are embraced in the solo and allowing them to sound.

809,566. **SEWING-MACHINE FEED AND LOOP-TAKER ACTUATING MECHANISM.** MARTIN HEBLER, Hinsboth, N. J., assignor to The Singer Manufacturing Company, a Corporation of New Jersey. Filed June 13, 1905. Serial No. 264,769.



Claim.—1. In a sewing-machine, the combination with the frame comprising a bed-plate and a hollow bracket-arm, and a rotary main shaft journaled in the bracket-arm, of stitch-forming mechanism comprising a loop-taker and a rotary shaft mounted beneath the bed-plate for imparting a rotating motion to said loop-taker, feeding mechanism disposed beneath the bed-plate, metallic connections disposed within and inclosed by said bracket-arm intermediate the main shaft and feeding mechanism, pulley-wheels mounted upon the main and looper shafts external to said bracket-arm, a non-metallic belt connecting said pulley-wheels, a housing inclosing said pulley-wheels and connecting-belt, and means for removably securing said housing to said bracket-arm.

2. In a sewing-machine, the combination with the frame comprising a bed-plate and a hollow bracket-arm formed with two closed vertical compartments one removable from the other and means for securing the same together, and a rotary main shaft journaled in said bracket-arm and extending through the upper portion of both of said compartments, of a plurality of lower shafts mounted beneath the bed-plate, pulley-wheels applied to said main shaft and one of the lower shafts within the removable compartment of said bracket-arm and a non-metallic belt connecting said pulleys, and metallic connections within the other compartment of said bracket-arm intermediate said main shaft and others of the lower shafts.

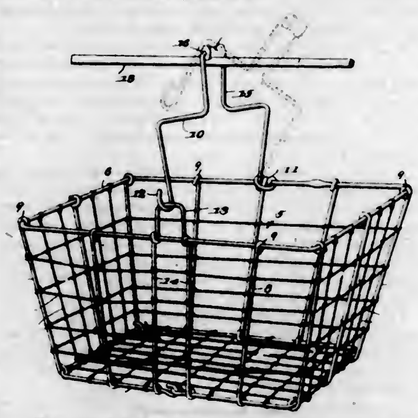
809,567. **TABLEWARE AND LIKE ARTICLES.** GUSTAVE A. HENCKEL, East Orange, N. J. Filed July 27, 1905. Serial No. 271,427.

Claim.—1. In a tableware article, the combination with a base having a socket and a spring clamping-thimble therein, said thimble comprising a spiral spring, of a receptacle having a stem within said socket and thimble and gripped and held by the latter, the convolutions of said spring surrounding said stem.

2. In a tableware article, the combination with a base having a socket and a spring clamping-thimble therein, said thimble comprising a spiral spring, said base having also a steadying-skirt, of a receptacle adapted to be received and steadied by said skirt, said receptacle having a stem within said socket and thimble and gripped and held by the latter, the convolutions of said spring surrounding said stem.

3. As an article of manufacture, a separable base for tableware, comprising a base-piece having a socket adapted to receive the projecting stem of a receptacle, said socket having within it a spiral spring arranged axially, its convolutions adapted to surround and grip such stem, said spring forming a clamping-thimble.

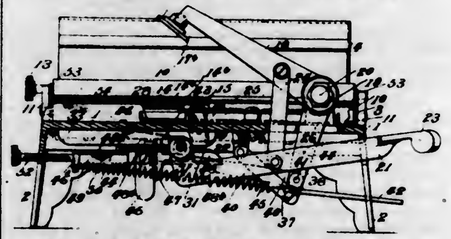
809,568. **CLOTHES-PIN BASKET.** SAMUEL W. HURLBURT, Creston, Iowa, assignor of one-half to Lansing W. Hurlburt, Creston, Iowa. Filed Oct. 7, 1904. Serial No. 227,582.



Claim.—1. A device of the class described comprising a receptacle, a handle pivoted to the receptacle and having its free end provided with a terminal hook adapted to detachably engage the receptacle and its intermediate portion bent upwardly beyond the general plane of the top of said handle to form a loop adapted to receive the clothes-line, said handle extending in a substantially horizontal plane on each side of the loop, and a roller journaled on the handle at said loop.

2. A device of the class described comprising a receptacle formed of an upper and lower horizontal frame connected by vertical stays, a handle having one end thereof pivoted to the upper frame and engaging each side of one vertical stay and its opposite end provided with a terminal hook, the intermediate portion of said handle being bent to form an upwardly-extending loop provided with a roller, and a keeper adapted to engage the terminal hook of the handle and formed by extending the intermediate pair of stays on one side of the basket above the general plane of the upper frame.

809,569. **STAMP-AFFIXING MACHINE.** OLIVER W. JOHNSON, Cleveland, Ohio. Filed Dec. 20, 1904. Serial No. 237,676.



Claim.—1. In a stamping-machine, the combination of a support, a cutter-bar pivoted to the support, a cutter carried by said cutter-bar, a crank-arm projected from the cutter-bar, a moistener movable upon the support, a link connection between the moistener and the crank-arm aforesaid, a lever pivoted to the support and operably connected with the cutter-bar, an actuating-bar mounted upon the support and connected with the crank-arm aforesaid, and a stamp-holder movably mounted upon the support for actuation by the actuating-bar aforementioned.

2. In a stamping-machine, the combination of a support, a carriage movably mounted upon the support, a stamp-holder upon said carriage, cutting mechanism including a pivoted cutter-bar, a crank-arm projected from said cutter-bar, a moistener slidably mounted upon the support, a link connecting the moistener with the crank-arm, an operating-lever pivoted to the support and operably connected with the cutter-bar, an actuating-bar slidable upon the support and pivotally connected with the crank-arm aforesaid, an engaging member extended from the actuating-bar, and coöperating with the carriage to advance the same at a step-by-step movement, and means for disengaging the actuating-bar from the carriage.

3. In a stamping-machine, the combination of a support, a movable stamp-holder adapted to receive a sheet of stamps, cutting mechanism, means for feeding the stamps from the holder to expose a longitudinal row of stamps to the action of the cutting mechanism, means for actuating the holder to advance the row of stamps as the same are severed, and means other than the aforesaid actuating means for adjusting the holder to properly aline transverse perforations separating the stamps with relation to the cutting mechanism.

4. In a stamping-machine, the combination of a support, a carriage movably mounted thereon, cutting mechanism, a stamp-holder upon said carriage, an actuating-bar coöperating with the carriage to advance the same, means for normally holding the actuating-bar in coöperation with the carriage, a lock device coöperating with the carriage to position the same at in ascertained adjustment, and means for adjusting the lock device to properly aline transverse perforations separating sheets of stamps with relation to the cutting mechanism.

5. In a stamping-machine, the combination of a support, a carriage reciprocally mounted thereon, cutting mechanism, a stamp-holder upon the carriage and adapted to receive a sheet of stamps to be fed to the cutting mechanism, an actuating-bar engaging the carriage to advance the same, means for operating said actuating-bar, a guide member coöperating with the actuating-bar, a lock device carried by the guide member and coacting with the actuating-bar to position the carriage at an ascertained adjustment, and means for adjusting the guide member aforesaid to thereby adjust the carriage to properly aline transverse perforations separating stamps relative to the cutting mechanism.

6. In a stamping-machine, the combination of a support, a carriage mounted upon the support, a stamp-holder mounted upon the carriage, a cutting-plate carried by the support, a pivotally-moving cutter-bar, a cutter carried by said cutter-bar and coöperating with said cutter-plate, means for feeding the stamps from the stamp-holder to the cutting mechanism, an actuating-bar connected with the cutter-bar and engaging the carriage to impart movement thereto, a moistener, and means for disengaging the actuating-bar from the carriage.

7. In a stamping-machine, the combination of a support, a carriage reciprocally mounted thereon, a stamp-holder upon the carriage, an actuating-bar engaging the carriage, means for actuating said bar, means for normally holding said bar in engagement with the carriage, and means for throwing the actuating-bar out of coöperation with the carriage.

8. In a stamping-machine, the combination of a support, a carriage reciprocally mounted thereon, a stamp-holder upon the carriage, an actuating-bar engaging the carriage, means for actuating said bar, means for normally holding said bar in engagement with the carriage, and a lock device coöperating with the actuating-bar aforesaid to position the carriage at an ascertained adjustment.

9. In a stamping-machine, the combination of a support, a carriage reciprocally mounted thereon, a stamp-holder upon the carriage, an actuating-bar engaging the carriage, means for actuating said bar, means for normally holding said bar in engagement with the carriage, means for throwing the actuating-bar out of coöperation with the carriage and a lock-pawl coöperating with the actuating-bar to position the carriage at an ascertained adjustment.

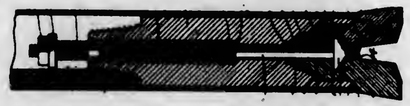
10. In a stamping-machine, the combination of a support, a carriage mounted thereon, a stamp-holder mounted upon the carriage, a moistener slidably mounted upon the support, a tank, and a spring-actuated roller partially immersed in the tank and adapted to contact with the under side of the moistener, as specified.

11. In a stamping-machine, the combination of a support, a reciprocally-mounted carriage upon said support, a stamp-holder carried by said support, feeding-rollers mounted upon the carriage to feed stamps from the stamp-holder, a cutting-plate arranged upon the support, a cutter-bar pivoted to the support, a cutter carried by said bar and coöperating with the cutting-plate, a plurality of lugs and teeth projecting from the carriage, an actuating-bar normally engaging the teeth of the carriage, a lock device coöperating with said actuating-bar to fix the position of the carriage, a moistener reciprocally mounted upon the support, and connections whereby the actuating-bar, the moistener and the cutter-bar are simultaneously operated.

12. In a stamping-machine, the combination of a stamp-holder adapted to receive a sheet of stamps, and cutting mechanism embodying a bed-plate and a cutter coöperating with said plate and having cutting edges extending at an angle to each other, the plate and cutter being arranged to effect cutting action approximately from a point at the angle at which the cutting edges of the cutter meet.

13. In a stamping-machine, the combination of a stamp-holder adapted to receive a sheet of stamps, and cutting mechanism embodying cutting elements, each having coöperating cutting edges extending at an angle to each other, the said elements being arranged to begin cutting from the angle at which the cutting edges of each element meet.

809,570. **UNDERREAMER.** FREDERICK W. JONES, Santa Paula, Cal., assignor to Edward North and Edward Double, Los Angeles, Cal. Filed Aug. 30, 1904. Serial No. 223,668.



Claim.—1. An underreamer of the class described comprising a centrally-bored mandrel having a cylindrical recess in its lower end, a recess above said cylindrical recess, a beveled shoulder between said upper recess and said cylindrical recess, a rod movable longitudinally in the bore of the mandrel and having a head on its lower end and a pair of cutters recessed on their opposing inner sides to receive the lower portion of said rod and the head of said rod, each of said cutters having a semicylindrical portion of a diameter to fit in the cylindrical recess of the mandrel, a semiconical upper portion to fit in the upper recess of the mandrel, a beveled shoulder to engage the upper beveled shoulder of the mandrel, a lower portion of a diameter exceeding that of the cylindrical recess of the mandrel, a beveled shoulder between the semicylindrical portion and the said portion of enlarged diameter, the said portions of enlarged diameter having their inner opposing sides oppositely beveled to form wedge-shaped openings between them.

2. An underreamer comprising a centrally-bored mandrel having a cylindrical recess in its lower end and a recess above said cylindrical recess, a beveled shoulder or abutment between said recesses, a spring-actuated rod slidable in said central bore, said rod having a head at its lower end, tilting slips tiltingly mounted on said head, said slips provided with cutting edges and with shoulders adapted to contact with said beveled shoulder or abutment.

3. An underreamer comprising in combination a centrally-bored mandrel having a cylindrical recess in its lower end and a second and smaller recess above said cylindrical recess, an inclined or beveled shoulder or abutment being provided between said recesses, a spring-actuated rod slidable in said mandrel, said rod provided with a pivot-head and underreaming bits or slips tiltingly mounted on said head, said bits provided with underreaming-faces and with shanks adapted to extend up into said recesses, said shanks having reduced upper portions adapted to fit within the upper recess.

4. An underreamer comprising a hollow mandrel, a spring-actuated rod slidable therein, said mandrel having at its lower end a cylindrical chamber and an inner and smaller chamber above said cylindrical chamber, an inclined or beveled abutment formed between the adjoining ends of the walls of said chambers, reaming-bits mounted on said rod and provided with surfaces adapted to contact with said inclined shoulder or abutment to tilt said bits.

5. An underreamer comprising a mandrel having a recess or chamber in its bottom and an inclined or beveled abutment in the said chamber, a spring-actuated rod slidable in said mandrel, said spring-actuated rod having a head of a form similar to an arrow-head, tilting slips or bits having sockets corresponding to the wings of said arrow-head into which said arrow-head is adapted to fit, said slips or bits provided with shanks adapted to be drawn up into said chamber and provided with inclined shoulders adapted to abut against said beveled or inclined shoulders in said chamber to tilt said slips or bits on said arrow-head as said slips or bits are drawn inward into said chamber.

6. An underreamer comprising a hollow mandrel furnished in

its lower end with a chamber provided at an intermediate portion with an inclined or beveled portion or abutment, a spring-actuated rod sliding through said chamber and extending up in said mandrel, two jaws pivoted to said rod respectively furnished at their upper ends with shanks extending above the pivot and into said chamber and furnished at their intermediate portions and above said pivot with inclined shoulders adapted to contact with said inclined abutment in said chamber.

7. An underreamer comprising a hollow mandrel furnished in its lower end with a chamber provided at an intermediate portion with an inclined or beveled portion or abutment, a spring-actuated rod sliding through said chamber and extending up in said mandrel, two jaws pivoted to said rod respectively furnished at their upper ends with shanks extending above the pivot and into said chamber, furnished above said pivot with inclined shoulders adapted to contact with said inclined abutment in said chamber, said shanks of said bits being of sufficient length to abut against the surface of the end wall of said chamber.

8. An underreamer comprising a mandrel provided in its lower end with an inwardly-extending chamber or socket, said chamber provided intermediate its length with an inclined or beveled abutment, a spring-actuated rod slidably mounted in said mandrel and extending through said socket or chamber up into the mandrel, two slips or bits pivoted to said rod and respectively furnished at their upper ends with shanks extending above the pivotal point to enter the upper end of said socket or chamber, said bits provided above said pivotal point with inclined shoulders adapted to abut against said inclined abutment in said socket or chamber to tilt said bits, said bits also provided with shoulders adapted to abut against the end of said mandrel.

9. An underreamer comprising a centrally-bored mandrel having a cylindrical recess in its lower side and a recess above said cylindrical recess, a shoulder or abutment between said recesses, a spring-actuated rod slidable in said central bore, said rod having a head at its lower end, tilting slips tiltingly mounted on said head, said slips provided with cutting edges and with inclined or beveled shoulders adapted to contact with said shoulder or abutment.

10. An underreamer comprising in combination a mandrel having a cylindrical chamber in its lower end and a tapering chamber above said cylindrical chamber and forming an inward extension thereof, a spring-actuated rod slidably mounted in said mandrel and extending up from said cylindrical chamber into said mandrel, reaming bits or slips tiltingly mounted on the lower end of said rod, said bits or slips having shanks extending above said lower end of said rod, said shanks having tapered upper ends corresponding to said tapered chamber, said bits or slips adapted to contact with the walls of said chambers and provided with shoulders adapted to contact with the end of said mandrel when said bits are in operative position.

11. An underreamer comprising a mandrel, a spring-actuated rod slidable therein, said mandrel having at its lower end a cylindrical chamber and an inner and smaller chamber above said cylindrical chamber, an abutment formed between the adjoining ends of the walls of said chambers, reaming-bits mounted on said rod and provided with surfaces adapted to contact with said abutment to tilt said bits.

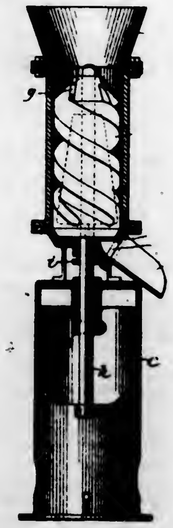
12. An underreamer comprising in combination a mandrel having a cylindrical chamber in its lower end and a tapering chamber above said cylindrical chamber and forming an inward extension thereof, a spring-actuated rod slidably mounted in said mandrel and extending up from said cylindrical chamber into said mandrel, the end of said rod in said cylindrical chamber being formed in the shape of an arrow-head, reaming bits or slips having sockets to receive the wings of said arrow-head and tiltingly mounted thereon, said bits or slips having shanks extending above said lower end of said rod and into said tapering chamber, the upper ends of said shanks being tapered to correspond to said tapered chamber, said bits or slips adapted to contact with the walls of said chambers and abut against the end wall of said tapered chamber and provided with shoulders adapted to abut against the end of the mandrel when in operative position.

13. An underreamer comprising a centrally-bored mandrel having a cylindrical chamber in its lower end and a recess above said cylindrical recess, a beveled or inclined shoulder or abutment formed between said recesses, a spring-actuated rod slidably mounted in said central bore, said rod having an arrow-head-shaped end in said cylindrical chamber, bits or slips having sockets corresponding to and adapted to receive the wings of said arrow-head and having shanks extending up into said cylindrical chamber and recess thereabove and provided with shoulders to abut against said abutment, said bits or slips abutting against the end wall of said recess when in operative position.

14. An underreamer comprising in combination, a mandrel, a spring-actuated rod slidable therein, said mandrel having in its lower end a cylindrical chamber and an inner and smaller chamber above said cylindrical chamber, an inclined or beveled abutment formed between the adjoining walls of said chambers, said rod provided with an arrow-head-shaped end, reaming-bits provided with sockets corresponding to and adapted to receive the wings of said arrow-head and thereby tiltingly supported on said rod, said bits provided with surfaces adapted to contact with said inclined shoulder or abutment to cause the bits to tilt.

15. An underreamer comprising a mandrel provided in its lower end with an inwardly-extending socket or chamber, said chamber provided intermediate its length with an inclined shoulder or abutment, a spring-actuated rod slidably mounted in said mandrel and extending through said socket or chamber up into the mandrel, two slips or bits pivoted to said rod and respectively furnished at their upper ends with shanks extending above the pivotal point to enter the upper end of said socket or chamber, said bits or slips provided with inclined shoulders above said pivot-point to abut against said inclined abutment in said socket or chamber to tilt said bits.

809,571. POI-MACHINE. ERNST KÖPKE, Honolulu, Hawaii. Filed Dec. 1, 1904. Serial No. 235,069.



Claim.—1. A machine for making poi or the like, comprising a vertical cylindrical body, its lower head having an outlet, a feeding-hopper at top of body, a supporting-base, a centrally-located shaft, means for revolving same, a drum mounted on the shaft within the cylinder between the hopper and head, said drum having beveled ends and spiral grooves in its surface tapering toward the lower end, and knives or cutting edges on the upper beveled end of said drum, substantially as described.

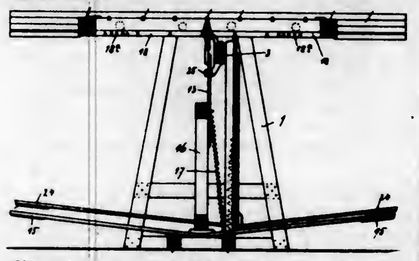
2. In a machine for making poi and the like, the cylindrical body, a recessed head at its lower end having an outlet, a shaft revoluble within the body and carrying a spirally-grooved drum having a beveled lower end fitting the recessed head, knives or cutting edges on the upper end of said drum and means for raising or lowering said shaft whereby the distance between the lower end of the drum and the head may be adjusted, substantially as described.

3. In a machine for making poi or the like, the cylindrical body, a recessed head at its lower end, a centrally-located shaft revoluble within the body and carrying a cylindrical drum beveled at both ends and having spiral grooves in its surface between the beveled ends, and knives or cutting edges fastened to the upper beveled end of said drum, the grooves in the drum tapering toward its lower beveled end, substantially as described.

4. In a machine for making poi or the like, the combination of

a vertical body having a feeding-hopper at its upper end and a central shaft and spirally-grooved drum revoluble therein, knives on the upper end of said drum, a base on which the body is mounted, a bevel-pinion supported in a sleeve-bearing in the base, a driving-gear journaled in the base above the wheel, the drum-shaft passing down into the base and through the pinion and connected thereto by a spline, a bearing for the lower end of the shaft, and means for adjusting the bearing.

809,572. TUFTING-MACHINE. WILLIAM B. LATIMER, Utica, N. Y., assignor to H. R. Latimer, Utica, N. Y. Filed Mar. 5, 1903. Serial No. 146,360.



Claim.—1. In a tufting-machine, the combination of a tufting-table having holders for securing the washers in definite locations thereon, of a mechanism arranged under the table for spreading the prongs of the staple, after being passed through the washer, the table and staple-spreading mechanism being relatively movable to provide for having the staples and spreading mechanism register with more than one washer-holder, substantially as set forth.

2. In a tufting-machine, the combination of a series of staple-expanders supported and arranged in the machine, of a movable table having washer-holders adapted to be shifted with reference to the expanding devices to cause the washer positions to register with the expanders, substantially as set forth.

3. A washer-holder for tufting-machines, having a base part and a projection adapted to be received in the opening of the washer and substantially fill the same diametrically, said projection being grooved or cut away on its sides to provide passages for the tufting-button prongs, and the base part cut away to afford clearance-spaces, for the expanded tufting-button prongs when being removed, substantially as set forth.

4. The combination in a tufting-machine of a table, having a washer-receiving projection adapted to be received in the opening of the tufting-button washer, said projection being elongated in one direction to substantially fill the opening in the washer diametrically, and being comparatively narrow in the other direction, whereby openings are provided for the prongs of the tufting-button, and a clenching device arranged below said projection, consisting of a pair of simultaneously-opening jaws adapted to engage and spread the prongs of the button, substantially as set forth.

5. In a tufting-machine, the combination of a tufting-table, having means for securing the tufting-button washer in position thereon, an opening through the table at the washer position and a spreader for the prongs of the tufting-button, consisting of a pair of simultaneously-opening jaws, and mechanism for operating same, substantially as set forth.

6. The combination in a tufting-machine of a table, having an opening, a point or projection supported in said opening adapted to be received in the opening of the tufting-button washer and fill the washer-opening diametrically in one direction, while affording openings for the prongs of the tufting-button at the sides of the diametrical line, a pair of simultaneously-opening spreading jaws located beneath the said projection and having their hinging-joint substantially parallel with the plane of the said projection, substantially as set forth.

7. The combination in a tufting-machine of a table movably supported, having means for securing tufting-button washers in position thereon, with an opening beneath said washer when in position, spreading mechanism for the prongs of the tufting-button supported on the frame in position to operate on the prongs of the tufting-button, the said tufting-table being movable to bring one or more of the washer positions to register with the spreading mechanism, substantially as set forth.

8. The combination in a tufting-machine of a movable table, having means for securing the washers of tufting-buttons in position thereon, with an opening beneath the washer positions, a spreading mechanism for the prongs of the tufting-buttons, consisting of a pair of simultaneously-opening jaws hinged together, and said hinging-point being supported close to the under side of the table by an arm from the main frame, substantially as set forth.

9. The combination of a tufting-table having projections adapted to pass into or through the openings in the tufting-washers, and locate and hold them, of an expanding mechanism arranged below the table and adapted to operate after the button is placed in its final position simultaneously on both prongs of the tufting-button to bend the prongs to secure the washer, substantially as set forth.

10. The combination in a tufting-machine of a table, washer-holders having a fixed projection adapted to be received in the washer-opening and of a form to substantially fill the washer-opening diametrically and afford passages at each side for the prongs of the button through the washer-opening, and a movable button-prong bender arranged immediately beneath the washer-holder, substantially as set forth.

11. A holder for a tufting-button washer for tufting-machines, consisting of a base, having a projection adapted to pass into or through the opening in the washer, elongated in one direction to substantially fill the opening in the washer diametrically, while affording clearances for the prongs of the tufting-button at either side, said base being cut away to make provision for placing the button without spreading the prongs materially, and to permit the removal of the button and washer after the prongs have been spread, substantially as set forth.

809,573. BURIAL-CASKET. MONROE S. LEECH, Chicago, Ill. Filed Aug. 21, 1905. Serial No. 274,999.

Claim.—1. In a casket, a flat glass base thicker near its outer edge, a glass cover interfitting with said base, and a metallic reinforcing means underlying said base and inturned over the edges thereof to protect the same.

2. In a casket, a flat glass base thicker near its outer edges provided with a channel in its thickest portion, a glass cover interfitting in said channel, a metallic reinforcing means extending under the base, and inturned over the edge thereof.

3. In a casket, a flat glass base thicker near its outer edges, a glass cover, metallic reinforcing means extending under the base and inturned over the edges thereof, and handles secured to the inturned portion of said metallic reinforcing means.

809,574. ORNAMENTAL COMB. WALTON J. METCALF and JOHN W. PROBERTS, Leominster, Mass. Filed Mar. 16, 1905. Serial No. 250,410.

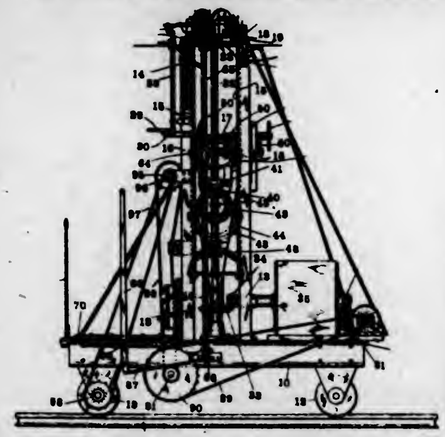
Claim.—1. In a comb of the character described, a suitable back and teeth, the said back having an opening, an ornamental plate lying against the back of the comb and exposed through the opening, a retaining-band, bearing against the plate and clips carried by the comb, and bent to overlie the outer surface of the retaining-band, substantially as described.

2. In a comb of the character described, a suitable body and teeth, the said body having suitably-shaped openings, plates fitting within the openings, a retaining-band having a flat surface bearing against each of said plates, the outer surface of said retaining-bands being convex, flexible clips carried by the comb and adapted to over-

lie the convex surface of the retaining-band, the ends of the said clips extending toward and terminating near the back of the comb.

2. In a device of the character described, a comb having a back provided with openings, plates fitting within the openings, the back of said comb, around each opening, being recessed to form a seat for the plate, a retaining-band having a flat contacting surface in engagement with the plate, flexible clips carried by the comb and adapted to overlie the outer surface of the retaining-band.

809,575. POWER-SLEDGE. PETER C. MOSS, Elwood, Ind., assignor to American Sheet and Tin Plate Company, Pittsburg, Pa., a Corporation of New Jersey. Filed Nov. 30, 1904. Serial No. 234,282.



Claim.—1. In a power-sledge, the combination with a portable carriage, of a cross-head carried thereby, a plurality of threaded vertical shafts journaled on the portable carriage and engaging said cross-head, intermediate connections between said several threaded shafts for causing simultaneous movement thereof, a reciprocating hammer-carriage mounted on the cross-head, means for reciprocating said hammer-carriage on the cross-head, a vertically-reciprocable hammer mounted on the hammer-carriage, and means for reciprocating said hammer.

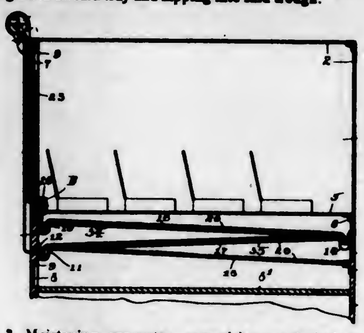
2. In a power-sledge, the combination with a portable carriage, of a cross-head carried by said carriage and vertically adjustable thereon, a hammer-carriage mounted on said cross-head and horizontally reciprocable thereon, a hammer carried by the hammer-carriage and vertically reciprocable thereon, a motor mounted on the portable carriage, and intermediate independently-controllable connections between said motor and the hammer-carriage and hammer whereby the hammer-carriage and hammer may be independently or simultaneously reciprocated.

3. In a power-sledge, the combination with a portable carriage, of a cross-head carried thereby, means for vertically adjusting said cross-head on the carriage, a hammer-carriage horizontally reciprocable on said cross-head, a horizontal shaft journaled on the cross-head, a splined driving connection between said shaft and the hammer whereby said hammer may be vertically reciprocated by rotation of the shaft, a crank-and-pitman driving connection for the hammer-carriage, means for varying the effective length of the crank thereof, a motor, and intermediate independently-controllable driving connections between said motor and said shaft and said crank, substantially as and for the purpose set forth.

809,576. TOBACCO-MOISTENING APPARATUS. HENRY J. MURRAY, Courtney, N. D. Filed Aug. 15, 1904. Serial No. 220,731.

Claim.—1. Apparatus of the class set forth, comprising an inclosing case, means for permitting a current of air to pass through said case, a series of troughs in the case, a water-supply tank, means for feeding water from said tank to said troughs, means for regulating the feed-supply, means for preventing the water overflowing said troughs, a series of trays in said case, and diffusing-cloths on said trays and projecting into said troughs.

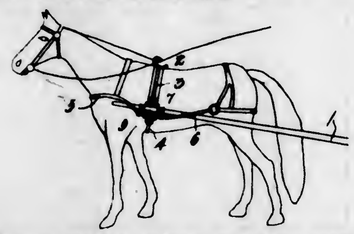
2. A device of the class set forth, consisting, in combination, of an inclosing case, means for permitting a current of air to circulate in said case, a trough in the case, a water-supply tank, a feed connection between said tank and trough, means controlled by the humidity in said case for regulating said feed connection, means for preventing the water overflowing said trough, a tray in said case, and a diffusing-cloth on said tray and lapping into said trough.



3. Moistening apparatus, comprising an inclosing case, a source of liquid-supply, a trough in said case, a feed connection between said source of liquid-supply and trough, means affected by the humidity in said case for automatically regulating the feed-supply, means for permitting a current of air to pass through said case to diffuse the liquid therein, means for checking the supply of liquid to said trough, a tray provided with openings passing therethrough, and a diffusing-cloth on said tray and lapping into said trough.

4. A device of the class set forth, consisting, in combination, of an inclosing case, a series of trays having openings passing therethrough, troughs in said case adjoining said trays, diffusing-cloths resting on said trays and lapping into said troughs, a water-supply tank, a feed connection between said tank and troughs, and means for checking the supply of water to said troughs, for the purposes specified.

809,577. HARNESS-TUG. JAMES S. MCKENZIE, Atlanta, Ga. Filed Nov. 26, 1904. Serial No. 234,676.



Claim.—A combined shaft-tug and holdback comprising a shaft-tug frame consisting of two plates permanently secured to a shaft, a holdback-rod permanently and yieldingly mounted in the tug-frame and buckles secured to the opposite ends of said holdback-rod for detachably connecting the holdback-strap and the breast-strap, and buckles above and below the tug-frame plates, substantially as described.

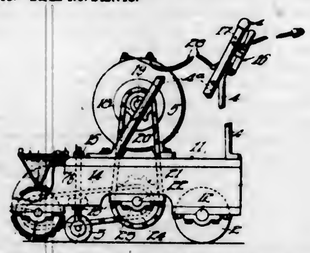
809,578. SPARKING PLUG. WILLIAM OTTAWAY, Aurora, Ill., assignor to Aurora Automatic Machinery Company, Aurora, Ill., a Corporation of Illinois. Filed Feb. 15, 1904. Serial No. 193,666.

Claim.—A sparking plug comprising an insulating-sleeve, a stem which passes through the sleeve and is provided with a head at its inner end, a packing interposed between said head and an opposing surface or shoulder on said sleeve, a cap applied to the outer end of said sleeve, a second cap which slides on the first-named cap and the head of which is perforated for the passage of the said stem, a nut on the stem adapted to bear against said second cap, and a spring interposed between said caps and acting to exert endwise tension on said stem.

809,579. COMBINED TWEEZERS, NEEDLE, AND EYE-CURETTE. ERNESTO PASTORE, New Haven, Conn. Filed May 18, 1905. Serial No. 260,971.

Claim.—The herein-described article consisting of a pair of tweezers comprising a flat central portion, legs extending downward therefrom, the central portion provided with a screw-threaded opening, a threaded shank arranged to be turned into said opening and carrying a needle-point at its lower end, said shank formed with a collar below its upper end, screw-threads above said collar, a loop inserted into the upper end of said shank, and a cap adapted to set over said loop and be turned onto said shank to a bearing on said collar whereby the shank and cap form a handle for the needle and also for the tweezers, and the tweezers or the needle form a handle for the loop, substantially as described.

809,580. FLOOR WAXING, POLISHING, AND CLEANING MACHINE. FRANK B. REICHENBACH, Los Angeles, Cal. Filed Jan. 26, 1905. Serial No. 242,718.



Claim.—1. A floor-waxing machine comprising a truck-frame, a motor on said frame, a rotary brush mounted on said frame, and connected to be driven by the motor, and a receptacle on the frame for supplying wax to said brush, said receptacle having a perforate bottom against which the brush wipes in its rotation.

2. A floor-waxing machine comprising a truck-frame, a motor on said frame, a rotary brush detachably mounted on said frame and connected to be driven by the motor, and a receptacle detachably mounted on the frame for applying wax to said brush, said receptacle having a perforate bottom against which the brush wipes in its rotation.

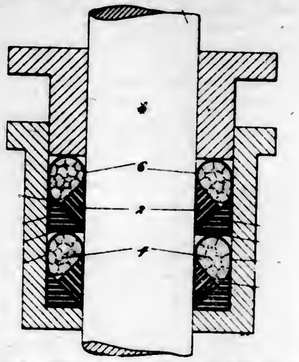
3. A floor waxing and polishing machine comprising a truck-frame, a motor on said frame, a shaft on the frame connected to be driven by the motor and interchangeable rotary waxing and polishing devices detachably mounted on said shaft, and a wax-carrying receptacle detachably mounted on the frame and having an opening for exposing the wax to the rotary waxing device.

4. A floor-waxing machine comprising a truck-frame, a motor on said frame, a rotary brush mounted on said frame and connected to be driven by the motor and a receptacle on the frame for supplying wax to the brush and roller means for engaging the floor and adjustably connected to the frame to adjust the height of the part of the frame carrying the rotary brush.

5. A machine for operating upon floors comprising a truck-frame, a motor on said frame, a rotary brush mounted on said frame and connected to be driven by the motor, a receptacle on the frame for supplying fluid to said brush and roller means for engaging the floor and adjustably connected to the frame to adjust the height of the part of the frame that carries the brush.

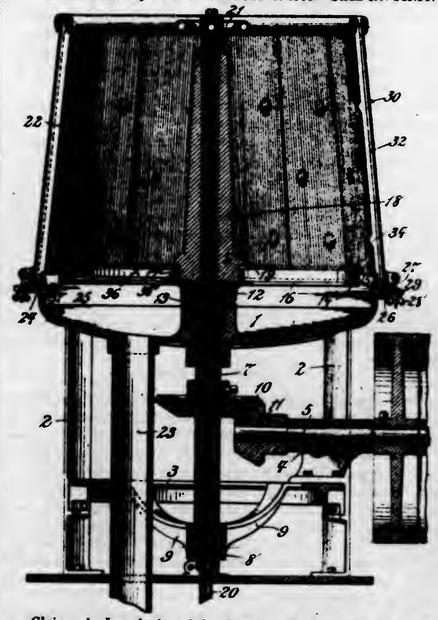
809,581. PACKING. CLEMENT RENTSCH, Philadelphia, Pa. Filed May 29, 1904. Serial No. 210,308.

Claim.—1. A packing comprising a pair of wedge members having the cross-sectional shape of right-angle isosceles triangles and having the side of one arranged in sliding contact with the hypotenuse of the other thereby forming a V-shaped groove, and a soft absorbent cushion arranged in the groove in contact with said members and having its face exposed on both sides of the packing whereby it can lubricate freely, substantially as described.



2. A packing comprising a pair of wedge members having the cross-sectional shape of right-angle isosceles triangles and having the side of one arranged to slide in contact with the hypotenuse of the other thereby forming a V-shaped groove, and a soft absorbent cylindrical cushion arranged in the groove and supported by said members to afford a lubricant-space and having its faces exposed on both sides of the packing whereby it can lubricate freely, substantially as described.

809,582. MACHINE FOR PEELING VEGETABLES. HENRY ROBINSON, Brooklyn, N. Y. Filed Jan. 7, 1905. Serial No. 240,047.



Claim.—1. In a device of the class described, an impelling and abrading member comprising a rotary disk composed of a horizontal flat striated portion and a raised portion extending from near the circumference inward and having two sides sloping down to the flat striated portion of said disk, substantially as described.

2. In a device of the class described, an impelling and abrading member comprising a rotary disk composed of a number of horizontal flat striated portions separated by raised portions at intervals extending from near the circumference inward, substantially as described.

3. In a device of the class described, an impelling and abrading member comprising a rotary disk composed of a horizontal flat striated portion and a rounded raised portion rising gradually from near the center toward the circumference, substantially as described.

4. In a device of the class described, an impelling and abrading member comprising a rotary disk composed of a horizontal flat striated portion, and a rounded raised portion bounded by two approximately radial edges extending from near the circumference inward and having a striated surface, substantially as described.

5. In a device of the class described, an impelling and abrading member comprising a rotary disk composed of a horizontal flat striated portion and a rounded raised portion bounded by two approximately radial edges extending from near the circumference inward, and having its surface striated at a material angle to the radii of the disk, substantially as described.

6. In a device of the class described, a containing vessel and a removable lining therefor the surface of which is striated and provided with rounded knobs adapted to enter the concavities of potatoes and the like, substantially as described.

7. In a device of the class described, a containing vessel and a removable lining therefor composed of vertical sections the surface of each of which is striated and provided with rounded knobs adapted to enter the concavities of potatoes and the like, substantially as described.

8. As an article of manufacture, an abrading element for peeling-machines comprising a striated strip having side ribs tapered at their ends, substantially as described.

9. As an article of manufacture, an abrading element for peeling-machines, comprising a striated strip having non-parallel sides and tapering ends, and provided with knobs on its striated surface, substantially as described.

10. As an article of manufacture an abrading element for peeling-machines comprising a striated strip with non-parallel sides and having ribs along said sides which ribs have tapering ends, substantially as described.

11. As an article of manufacture, an abrading element for peeling-machines, comprising a concave strip with non-parallel sides and tapering ends, and having striations on its concave surface making an acute angle with the median line of the strip, substantially as described.

12. As an article of manufacture, an abrading element for peeling-machines comprising a flat striated plate conforming roughly in outline to a sector of a circle and having isolated knobs on the working portion of its striated surface, substantially as described.

13. In a peeling-machine, a horizontal bowl having an upturned circular edge and a removable pot resting on said edge and having a deep circular lip fitting snugly within the edge of said bowl and having its inner surface sloping downward away from the center of the bowl, substantially as described.

14. In a peeling-machine, a horizontal bowl having an upturned circular edge and a removable pot provided with a bottom ring having an exterior flange extending upward and a deep interior lip fitting snugly within said bowl and having its inner surface sloping downward away from the center of the bowl, substantially as described.

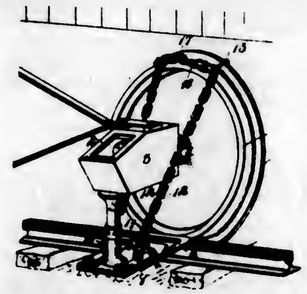
809,583. **BISMUTH DISALICYLATE AND PROCESS OF MAKING SAME.** BRUNO R. SEIFERT, Radebeul, near Dresden, Germany, assignor to Chemische Fabrik von Heyden Aktiengesellschaft, Radebeul, near Dresden, Germany. Filed Oct. 10, 1905. Serial No. 282,159.

Claim.—1. The manufacture of bismuth disalicylate which consists in causing a normal bismuth salt to act on a solution of a salicylic salt, the base of which forms a soluble salt with the acid of the bismuth salt, and in removing the free salicylic acid from the product of reaction by neutralization or extraction with indifferent solvents at a temperature at which the bismuth disalicylate is not yet split up into salicylic acid and bismuth monosalicylate, substantially as and for the purpose specified.

2. As a new article of manufacture the new salt, bismuth disalicylate, a chemical combination of one atom of bismuth with two molecules of salicylic acid, forming a whitish powder of neutral reaction, which is split up into free salicylic acid and bismuth monosalicylate by boiling water, substantially as and for the purpose specified.

809,584. **LIFTING-JACK.** JOHN J. SHANNON, Bangor, Me. Filed July 20, 1905. Serial No. 271,722.

Claim.—1. In a device of the character described, a block, said block being adapted to support a jack and being independent thereof, connections on the block adapted to engage the rim of a wheel, and means carried by the block for adjusting said block with relation to the wheel.



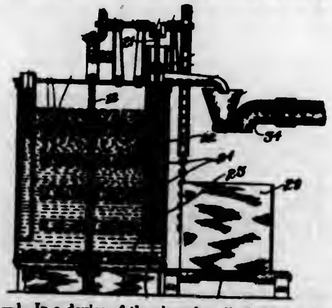
2. In a device of the character described, a block, said block being adapted to support a jack and being independent thereof, connections on the block adapted to engage the rim of a wheel, a brace carried by the block to engage the wheel, said brace being adjustable with relation to the block.

3. In a device of the character described, a block, said block being adapted to support a jack and being independent thereof, connections on the block adapted to engage the rim of a wheel, a slotted brace adapted to engage the wheel through the block and slots of the brace, the connections of the block engaging the eyebolts and causing them to bind against the brace.

4. In a device of the character described, a block adapted to support a jack, a brace for the block, said brace being approximately U-shaped, the parallel arms of the brace being slotted, eyebolts passing through the block and the slots of the brace, binding means for the eyebolts engaging the brace, and connections between the eyebolts and the rim of a wheel.

5. In a device of the character described, a block adapted to support a jack, a brace for the block, said brace being approximately U-shaped, the parallel arms of the brace being slotted, reinforcing-stripe carried by the block, eyebolts passing through the reinforcing-stripe, block, and slots of the brace, the eyes of the bolts bearing on the reinforcing-stripe, binding means on the bolts engaging the brace, and connections between the eyebolts and the rim of a wheel.

809,585. **MIXING AND MEASURING APPARATUS.** ROBERT C. SMITH, Oak Park, Ill. Filed Mar. 7, 1905. Serial No. 248,909.



Claim.—1. In a device of the class described, the combination with a tilting vessel having two compartments, of a raw-water pipe discharging into the two compartments of said tilting vessel alternately, a tank for chemical fluid, a measuring-pump for pumping chemical fluid from said tank and delivering it to said tilting vessel, a rock-shaft, a crank on said rock-shaft connected with the pump-rod of said pump, and gearing connecting the tilting vessel mechanically with said rock-shaft, the ratio and adjustment of said gearing being such as to cause an upward stroke of said pump-rod in unison with each single oscillation of said tilting vessel.

2. In a device of the class described, the combination with a tilting vessel having two compartments, of a raw-water pipe discharging into the two compartments of said tilting vessel alternately, a chemical-supply tank, a measuring-pump for pumping chemical fluid from said supply-tank and discharging alternately into the two compartments of said tilting vessel, said pump being actuated by the movements of said tilting vessel, a rock-shaft, a crank on said rock-shaft connected with the pump-rod of said pump, gearing connecting said tilting vessel mechanically with said rock-shaft, the ratio and adjustment of said gearing being such that each single oscillation of said tilting vessel causes a predetermined upward stroke of said pump-rod.

3. In a device of the class described, the combination with a tilting vessel having two compartments, of a raw-water pipe discharging into the two compartments of said tilting vessel alternately, a chemical-supply tank, a stirring device in said chemical-supply tank, a reciprocating measuring-pump for pumping chemical fluid from said tank and delivering it to said tilting vessel, a rock-shaft, a crank on said rock-shaft connected with the pump-rod of said pump, gearing connecting said stirring device with said rock-shaft, and gearing connecting said tilting vessel mechanically with said rock-shaft, the ratio and adjustment of said gearing being such that each single oscillation of said tilting vessel causes a predetermined upward stroke of said pump-rod.

4. In a device of the class described, the combination with a chemical-supply tank, of stirring mechanism in said tank, a tilting vessel having two compartments, a raw-water pipe discharging alternately into the two compartments of said tilting vessel, a measuring-pump for pumping chemical fluid from said supply-tank and discharging alternately into the two compartments of said tilting vessel, said pump being actuated by the movements of said tilting vessel by means of connecting-gearing serving to cause a complete up-and-down stroke of said pump in unison with each single oscillation of said tilting vessel, and gearing for connecting said tilting vessel mechanically with said stirring mechanism.

5. In a device of the class described, the combination with a chemical-supply tank, of a tilting vessel having two compartments, a raw-water pipe discharging alternately into the two compartments of said tilting vessel, and a measuring-pump for pumping chemical fluid from said supply-tank and discharging alternately into the two compartments of said tilting vessel, said pump being actuated by the movements of said tilting vessel by means of connecting-gearing serving to cause a complete up-and-down stroke of said pump in unison with each single oscillation of said tilting vessel.

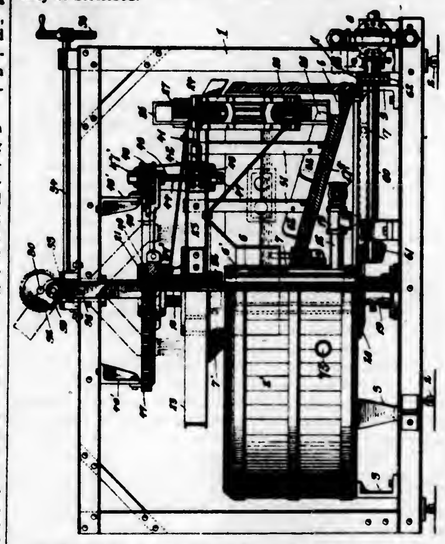
6. In a device of the class described, the combination with a chemical-supply tank, of a tilting vessel having two compartments, a raw-water discharge-pipe discharging alternately into the two compartments of said tilting vessel, a single measuring-pump for pumping chemical fluid from said tank and delivering it into the tilting vessel, said pump being actuated by the movements of said tilting vessel, a gearing between said pump serving to cause both an upward and a downward stroke of said pump in unison with each single oscillation of said tilting vessel, and means for adjusting the stroke of the pump relatively to a given movement of said tilting vessel.

809,586. **GOLD-SEPARATOR.** EBEN J. STERLING, Brooklyn, N. Y. Filed Feb. 1, 1905. Serial No. 243,699.

Claim.—1. In a gold-separator, the combination of a tank, a circular rack above said tank, a rotatable shaft extending upwardly through said tank, means for operating said shaft, a hub rotatable with and slidable on said shaft, means for sliding said hub on said shaft, arms secured to said hub, elevators rotatably mounted on said arms, laterally-extending shafts for operating said elevators, said shafts rotatably mounted on said arms and having gears on their inner ends and upwardly-extending shafts rotatably mounted on said arms and having gears on their lower ends meshing with the gears on the laterally-extending shafts and gears on their upper ends rotatable therewith and slidable thereon and meshing with said circular rack, substantially as described.

2. In a gold-separator, the combination of a tank, a circular rack above said tank, a pipe projecting up through said tank and having an exterior annular chamber provided with outlet-openings leading into said tank, a rotatable shaft extending upwardly through said pipe, means for operating said shaft, a hub rotatable with and slidable on said shaft, means for sliding said hub on said shaft, arms secured to said hub, elevators rotatably mounted on said arms, laterally-extending shafts for operating said elevators, said shafts rotatably mounted on said arms and having gears on their inner ends and upwardly-extending shafts rotatably mounted on said arms and having gears on their lower ends meshing with the gears on the laterally-extending shafts and gears on their upper ends rotatable therewith and slidable thereon and meshing with said circular rack, substantially as described.

3. In a gold-separator, the combination of a tank, a circular rack above said tank, a rotatable shaft extending upwardly through said tank, a hub rotatable with and slidable on said shaft, means for sliding said hub on said shaft, arms secured to said hub, scrapers carried by said arms, elevators rotatably mounted on said arms, laterally-extending shafts for operating said elevators, said shafts rotatably mounted on said arms and having gears on their inner ends and upwardly-extending shafts rotatably mounted on said arms and having gears on their lower ends meshing with the gears on the laterally-extending shafts and gears on their upper ends rotatable therewith and slidable thereon and meshing with said circular rack, substantially as described.



4. In a gold-separator, the combination of a tank, a circular rack above said tank, a rotatable shaft extending upwardly through said tank, means for operating said shaft, a hub rotatable with and slidable on said shaft, a block on the upper end of said shaft, a shaft rotatably mounted on said block and having a worm-wheel on one end and a disk on the other end, links having their upper ends pivoted to said worm-wheel and disk and their lower ends pivoted to said hub, a rotatable shaft having a worm meshing with said worm-wheel, arms secured to said hub, elevators rotatably mounted on said arms, laterally-extending shafts for operating said elevators, said shafts rotatably mounted on said arms and having gears on their inner ends and upwardly-extending shafts rotatably mounted on said arms and having gears on their lower ends meshing with the gears on the laterally-extending shafts and gears on their upper ends rotatable therewith and slidable thereon and meshing with said circular rack, substantially as described.

5. In a gold-separator, the combination of a tank, a circular rack above said tank, a rotatable shaft extending upwardly through said tank, means for operating said shaft, a hub rotatable with said shaft, arms secured to said hub, elevators rotatably mounted on said arms, laterally-extending shafts for operating said elevators, said shafts rotatably mounted on said arms and having gears on their inner ends and upwardly-extending shafts rotatably mounted on said arms and having gears on their lower ends meshing with the gears on the laterally-extending shafts and gears on their upper ends rotatable therewith and meshing with said circular rack, substantially as described.

6. In a gold-separator, the combination of a tank, a circular rack above said tank, a rotatable shaft extending upwardly through said tank, means for operating said shaft, a hub rotatable with said shaft, arms secured to said hub, scrapers secured to said arms, elevators rotatably mounted on said arms, laterally-extending shafts for operating said elevators, said shafts rotatably mounted on said arms and having gears on their inner ends and upwardly-extending shafts rotatably mounted on said arms and having gears on their

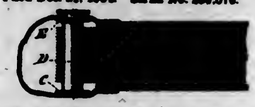
lower ends meshing with the gears on the laterally-extending shafts

having means for engagement with the lower, and a support from the

lower ends meshing with the gears on the laterally-extending shafts and gears on their upper ends rotatable therewith and meshing with said circular rack, substantially as described.

7. In a gold-separator, the combination of a tank, a circular rack above said tank, a pipe projecting up through said tank and having an exterior annular chamber provided with outlet-openings leading into said tank, a rotatable shaft extending upwardly through said pipe, means for operating said shaft, a hub rotatable with said shaft, arms secured to said hub, elevators rotatably mounted on said arms, laterally-extending shafts for operating said elevators, said shafts rotatably mounted on said arms and having gears on their inner ends and upwardly-extending shafts rotatably mounted on said arms and having gears on their lower ends meshing with the gears on the laterally-extending shafts and gears on their upper ends rotatable therewith and meshing with said circular rack, substantially as described.

809,587. LOOSE-LEAF BINDER. LEON SUSSMAN, Bayonne, N. J., assignor of one-half to Samuel Wilner and Rhea R. Wilner, New York, N. Y. Filed Dec. 31, 1904. Serial No. 239,076.



Claim.—1. A binder or holder for leaves and the like, comprising two sets of connected members, the members of one set being adapted to enter those of the other set, spring-pressed plungers mounted in the members of one set, and locking mechanism, operated by the movement of said plungers, to connect one set of members with the other, or disconnect it therefrom.

2. A binder or holder for leaves or the like, comprising a socket roughened on its inner surface, a slide adapted to be inserted into the said socket, a spring-pressed plunger in the slide, and means, operated by the movement of said plunger, for locking the slide to the socket, or releasing it therefrom.

3. A binder or holder for leaves or the like, comprising a socket roughened on its inner surface, a slide adapted to be inserted into the said socket, a spring-pressed plunger movable in the slide, and elastic means, controlled by the movement of the plunger, for locking the slide to the socket, or releasing it therefrom.

4. A binder or holder for leaves or the like, comprising a socket, a slide adapted to enter the said socket, a plunger movable in the slide, mechanism operated by the movement of said plunger, for locking said slide to the socket or releasing it therefrom, and a catch for holding the plunger in its releasing position.

5. A binder or holder for leaves or the like, comprising a set of connected sockets, a set of connected slides adapted to enter the said sockets, connected plungers movable in the said slides, locking mechanism operated by the movement of said plungers for locking said slides to the sockets or releasing them, and a catch for holding the plungers in the releasing position.

6. A binder or holder for leaves or the like, comprising a strip or bar and sockets carried thereby, another strip or bar carrying slides adapted to enter the said sockets, connected plungers movable in the said slides, locking mechanism, operated by the movement of said plungers, to connect or disconnect the said slides and sockets, and a catch for holding the plungers in the releasing position.

809,588. RACE-COURSE FOR AUTOMOBILES. JOHN B. THOMAS and JASPER LYNES, Lakewood, N. J. Filed Apr. 1, 1905. Serial No. 253,274.

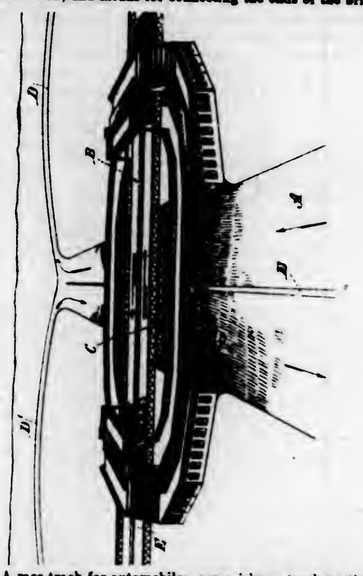
Claim.—1. A race-track for automobiles, comprising two straight portions crossing one another at different levels, each end of each straight portion being connected with each end of the other portion by means of loops.

2. A race-track for automobiles, comprising two straight portions crossing one another at different levels, each end of each straight portion being connected with each end of the other portion by means of loops, the straight portions being at least twice as wide as the looped portions.

3. A race-track for automobiles, comprising a plurality of track portions crossing at different levels, and loops connecting said track portions, there being a plurality of loops each having one end connected with the same end of one of the crossing track portions.

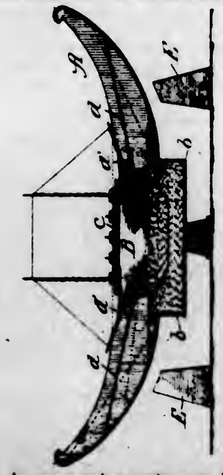
4. A race-track for automobiles, comprising two tracks crossing at different levels, means for joining the ends, and a grand-stand built around the crossing-point of the two tracks.

5. In a race-track for automobiles, two tracks crossing at a different level, a grand-stand consisting of one or more bridges spanning each track, and means for connecting the ends of the bridges.



6. A race-track for automobiles, comprising a track portion, a plurality of tracks crossing such track portion and each arranged at a level different from that of the track portion, and dissociated loops connecting said tracks with the track portion and forming a continuous course therewith.

809,589. AMUSEMENT APPARATUS. EDWIN S. TIMMONS, Chicago, Ill. Filed May 5, 1905. Serial No. 259,936.



Claim.—1. An amusement apparatus comprising, in combination, a water-receptacle, means for moving the receptacle to agitate the water therein, a boat supported by the water in said receptacle and means for preventing the boat from striking against the walls of the receptacle.

2. An amusement apparatus comprising, in combination, an oblong water-receptacle, means for rocking said receptacle to agitate the water therein, a boat supported by the water in said receptacle and means for preventing the boat from striking against the walls of the receptacle.

3. An amusement apparatus comprising, in combination, a water-receptacle, means for moving said receptacle to agitate the water therein, a boat supported by the water in said receptacle and means for preventing the boat from striking against the walls of the receptacle.

4. An amusement apparatus comprising, in combination, a water-receptacle, means for rocking said receptacle, buffers located below the opposite end portions of the said receptacle, a boat supported by the water in said receptacle, and means for preventing the boat from striking against the walls of the receptacle.

5. An amusement apparatus comprising, in combination, a water-receptacle, bearings therefor between its ends, means for rocking said receptacle on its bearings, a boat supported by the water in said receptacle and means for preventing the boat from striking against the walls of the receptacle.

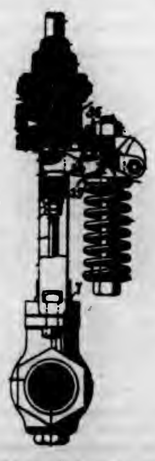
6. An amusement apparatus comprising, in combination, a water-receptacle, bearings on which said receptacle is pivotally mounted between its ends, gear and pitman rocking means for the receptacle, a boat supported by the water and means for preventing the boat from striking against the walls of the receptacle.

7. An amusement apparatus comprising, in combination, a water-receptacle, means for moving said receptacle for agitating the water therein, a boat supported by the water in said receptacle and means for maintaining the boat in substantially the same longitudinal position relative to the receptacle comprising resilient connections secured to said boat and said receptacle.

8. An amusement apparatus comprising, in combination, a water-receptacle, means for moving said receptacle to agitate the water therein, a boat supported by the water in said receptacle, and means for maintaining the boat in substantially the same longitudinal position with relation to the receptacle, comprising spring-equipped rods secured to the opposite ends of the boat and receptacle respectively.

9. An amusement apparatus comprising, in combination, a water-receptacle, means for moving said receptacle to agitate the water therein, a boat supported in the water in said receptacle, means for preventing the boat from striking the walls of the receptacle, a stationary platform adjacent to said receptacle and a gang-plank adapted to be raised and lowered to span the space between the boat and said platform.

809,590. PUMP-REGULATOR. JAMES P. WATSON and FREDERICK L. JAHN, Philadelphia, Pa., assignors to The Watson & McDaniel Company, a Corporation of Pennsylvania. Filed July 14, 1905. Serial No. 269,897.



Claim.—1. In a pump-regulator, a case, a steam-inlet and an outlet therefor, balanced steam-valves in the case, a stem for the valves, a framework supported on the case, a hydraulic cylinder supported on the framework and in alinement with the case, a chambered piston in the cylinder and adjustably connected to the valve-stem; a passage from the pump to the hydraulic cylinder; a spring supported out of alinement with the valves and piston, with means to adjust its tension; a lever fulcrumed upon the framework, a seat for the spring having means for engagement with the lever, and a support from the end of the lever opposite its fulcrum, which enters and is seated in the piston's chamber at a point near the head of the piston and where it receives its pressure.

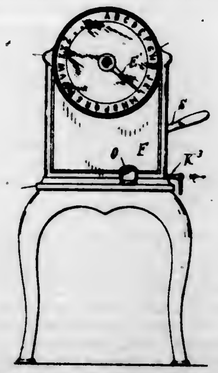
2. In a pump-regulator, the combination of balanced steam-valves, and a stem therefor, a hydraulic piston adjustably connected to the stem and in alinement therewith, a lever fulcrumed at its outer end and extending to the hydraulic piston, a spring adjustably suspended between the lever's fulcrum and the hydraulic piston and whereby the spring is placed out of alinement with the valves and piston and its movement is less than the movement of the valves and piston, depressions in the lever, a spring-seat having projections engaging the depressions, and a supporting means for the piston which engages the lever and extends to the point of pressure on the piston.

3. In a pump-regulator, a case with steam connections thereto and therefrom, a framework for the case and a hydraulic cylinder thereon in alinement with the case, a piston in the cylinder and adjustably secured to the valve-stem in direct alinement, a passage from a pump to the hydraulic cylinder, a lever pivotally supported at its outer end, a spring adjustably supported upon the framework and bearing upon the lever between its pivot and the piston to decrease its movement relative to the piston and valves, a speed limit adapted for adjustment to contact and restrict the lever's movement and the opening of the steam-valves, and a means of support from the lever to the piston which at one end engages the lever and at its opposite and engages the piston at its end which is subjected to hydraulic pressure.

4. In a pump-regulator, steam-valves and a hydraulic piston adjustably connected, a spring adapted to resist the pressure on the piston and seated upon a lever whereon is also seated an end bearing-support adapted to support the piston at its point subjected to pressure.

5. In a pump-regulator, steam-valves and a hydraulic piston adjustably connected, a spring supported in manner for its less movement than the movement of the valves and piston, and seated upon a lever having a pin-support for the piston and whereby the the piston is supported at its point subjected to pressure.

809,591. BLANK STAMPING OR IMPRESSING MACHINE. GEORGE W. HERNS, Cleveland, Ohio. Filed June 14, 1903. Serial No. 161,706.



Claim.—1. In a machine of the type set forth the combination with a matrix table or platen provided with a series of pivoted matrices, springs for holding said matrices in normal or non-operative position, means for moving said platen or table comprising an indicator a pivoted weight adapted to operate upon an individually-positioned matrix a blank-holder located in juxtaposition to said weight said blank-holder being movable so as to present successively a new surface to be operated upon, means for moving said blank-holder and means for feeding the blank to said blank-holder and ejecting the previously-completed blank from said blank-holder, said latter means comprising grasping-jaws an anvil located between said grasping-jaws means for opening and closing said jaws, and means for raising and lowering the anvil within said jaws, substantially as and for the purpose set forth.

2. The combination with a series of pivoted dies, and the movable weight, of a blank-holding chuck, means for simultaneously no-

tuating the said chuck and weight, an anvil-block operating in said

tioning, temporarily holding, releasing, and delivering the blank

a metallic angle-frame having one angle secured to the body portion,

809,594. SELF-ACTING MULTISPINDLE-MACHINE. HENRY

tuating the said chuck and weight, an anvil-block operating in said chuck, and a slide arranged beneath the said block and having an inclined face for raising and lowering the same.

3. The combination with the movable die and the means for actuating the same, of a blank-holding chuck comprising inner and outer shells, means for contracting the upper end of the inner shell as it is lowered, an anvil-block slidably mounted in the inner shell of the said chuck, and means for sliding said block in said shell, substantially as described.

4. The combination with the dies and the actuating means therefor, of a blank-holding clutch comprising an outer shell provided on its interior with an inclined surface, and an inner shell having its upper portion formed with a series of jaws having their outer surfaces inclined and being adapted to engage the inclined portion of the outer shell, means for holding the said shell in a depressed state within the outer shell, an anvil-block operating within the inner shell, and means for elevating the said inner shell and anvil-block.

5. In combination with the dies and the means for actuating the same, a chuck, an anvil-block arranged in the chuck, a blank-feed means, and a slide for simultaneously actuating said anvil-block and blank-feeding means.

6. In combination with the chuck comprising inner and outer shells, the inner shell having spring-arms engaging an inclined flange of the outer shell, an anvil-block arranged in said chuck, means for successively elevating the inner shell and anvil-block respectively, and means for feeding blanks to said chuck operated by said last-named means.

7. In combination with a chuck and a die, an ejecting means arranged in the chuck, a means for operating the said ejecting means, and means connected directly to said last-named means for feeding blanks to the chuck.

8. In combination with the chuck comprising coöperating inner and outer shells, an ejecting means arranged in the chuck, and a slide formed with cam-faces for successive engagement with the said inner shell and ejecting means respectively.

9. In combination with the blank-holding means, and the dies, means for bringing the said dies successively over said blank-holding means, a weighted lever for engagement with said dies, a pair of levers arranged one above the other, a cam-lever adapted when engaged by the upper of the first-named levers to actuate the lower thereof, said upper lever when operated elevating said weighted lever, and means carried on the inner end of said lower lever for imparting an intermittent movement to said blank-holding means.

10. In a machine of the type set forth, the combination with the blank-holding means, the dies, and the ejecting means operating through the said blank-holding means, of a blank-feeding means, and means rigidly connected to said last-named means, for releasing the blank in said holding means and actuating the ejecting means.

11. In a stamping-press, printing mechanism having individual die elements, mechanism comprising means for positioning, temporarily holding, releasing and delivering a blank, and means for effecting a stamping of the characters in a circle upon the blank while temporarily held.

12. In a stamping-press, printing mechanism having individual die elements, means for moving a blank into a position with its edge lapped by the printing mechanism, and also for temporarily holding the blank in and delivering it from such position, and means for effecting a stamping of the characters in a circle upon the blank.

13. In a stamping-press, printing mechanism having individual die elements, blank-handling mechanism comprising means for positioning, temporarily holding, releasing and delivering a blank, and means for effecting a spacing action, through relative movement of the blank and die elements, for stamping the characters in a circle upon the blank.

14. In a stamping-press, printing mechanism having a plurality of die elements, means for selecting individual die elements with reference to the printing position, blank-handling mechanism comprising means for positioning, temporarily holding, releasing, and delivering a blank, and means for effecting a stamping of the characters in a circle upon a blank.

15. In a stamping-press, printing mechanism having individual die elements, blank-handling mechanism having a rotatable anvil-support for the blank and also having means for positioning, temporarily holding, releasing, and delivering the blank, selecting means for the die elements, and means for effecting character-spacing through the movement of the anvil-support.

16. In a stamping-press, printing mechanism having individual die elements, blank-handling mechanism having a step-by-step rotated anvil-support for the blank and also having means for positioning, temporarily holding, releasing, and delivering the blank, and selecting means for the die elements.

17. In a stamping-press, printing mechanism having individual die elements, blank-handling mechanism having a rotatable anvil-support for the blank and also having means for positioning, temporarily holding, releasing, and delivering the blank, selecting means for the die elements, and operating mechanism having means for actuating the die elements and also for effecting a character-spacing through the medium of the anvil-support.

18. In a stamping-press, blank-handling mechanism having an anvil-support for the blank and also comprising means for positioning, temporarily holding, releasing, and delivering a blank, a die-holder arranged in overlapping relation to the anvil-support and having a plurality of die elements, means for selecting the individual die elements and operating mechanism comprising means for actuating the selected die element, and also for effecting a character-spacing movement of the blank.

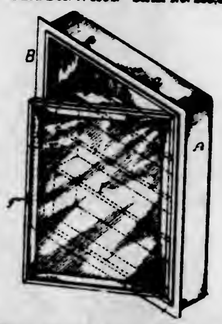
19. In a stamping-press, blank-handling mechanism having an anvil-support for the blank and spacing mechanism coöperating with the anvil-support, said blank-handling mechanism also comprising means for positioning, temporarily holding, releasing, and delivering a blank, a die-holder bearing an overlapping relation to the anvil-support and having a plurality of die elements, means for selecting the individual die elements, and operating mechanism comprising means for actuating the said spacing mechanism for the anvil-support and also for actuating the selected die element.

20. In a machine of the class described, printing mechanism having individual die elements, blank-handling mechanism including an anvil-support for the blank and comprising means for positioning, and delivering the blank, a holding device for clamping and releasing the automatically-positioned blank upon the anvil, and controlling mechanism comprising means for setting and releasing the holding device respectively after the positioning of the blank and at the completion of the stamping operation.

21. The combination with the dies, a pivoted weight and operating means therefor of a blank-holding chuck, comprising inner and outer shells, means for contracting the upper portion of the inner shell, an anvil-block operating in said inner shell, and a slide formed with cams adapted to elevate successively the inner shell of the chuck and the anvil-block.

22. The combination with the dies, a weight, and the actuating means therefor, of the blank-hopper, a chuck, means for feeding the blanks from the hopper to the chuck, a finger engaging the upper face of the blanks when arranged in the chuck, an anvil-block operating in the chuck, means for elevating the anvil-block for ejecting the blank, and means for rotating the said chuck.

809,592. **METALLIC WALL-CLOSET.** DAVID H. WATTS, Jr., Philadelphia, Pa. Filed Dec. 7, 1904. Serial No. 235,864.



Claim.—1. The combination in a closet, of a metallic body portion arranged to fit in the space between the two walls of a partition, and a frame secured to the open end of the body portion and overlapping one wall forming a finish, and a door hung to said frame, substantially as specified.

2. The combination of a body portion, lugs thereon, an angle-frame having one member secured to the lugs, the other member extending through one wall of the partition, a facing-frame secured to the angle-frame, and a door hung to the facing-frame, substantially as specified.

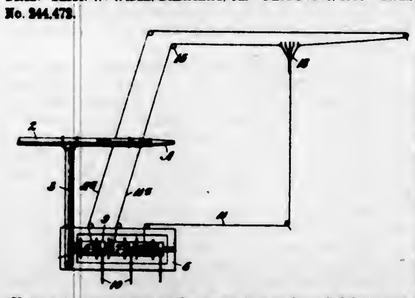
3. The combination in a closet, of a body portion adapted to be mounted between the walls of a partition, lugs on the body portion, a metallic angle-frame having one angle secured to the body portion, the other angle extending through one wall of the partition and a metallic angle facing-strip overlapping the wall and secured to the angle-frame, substantially as specified.

4. The combination in a closet, of a body portion made of cast metal and enameled on the inside, shelf-supports secured to the body portion, shelves mounted thereon, a metallic angle-frame having one member secured to the body portion, the other member extending through one wall of the partition, an angle facing-frame having one member overlapping one of the members of the angle-frame and the other member overlapping the wall of the partition, and a door pivoted to the facing-frame, substantially as specified.

5. The combination in a closet, of a body portion, a frame secured to the body portion, a door, concealed pivots by which the door is hung to the frame, and a washer on the pivot between the lower portion of the door and the frame, substantially as specified.

6. The combination in a closet, of a partition, studding therein, a cast-metal body portion having lugs and having its inner surface enameled, a metallic angle-frame, screws fastening one member of the frame to the lugs of the body portion, the other member of the frame extending through the wall of the partition and flush with the outer surface thereof, an angle facing-frame, screws fastening one member of the said facing-frame to the angle-frame, the other member of the facing-frame overlapping the wall of the partition, a door mounted in the facing-frame, concealed pivots by which the door is hung to the frame, said door being made in the form of a frame, a glass mounted in the frame, and a backing for the glass also mounted in the frame, substantially as specified.

809,593. **DEVICE FOR REMOVING MINING AND OTHER DEBRIS.** SIMON W. WERLE, Bakersfield, Cal. Filed Feb. 6, 1905. Serial No. 244,473.



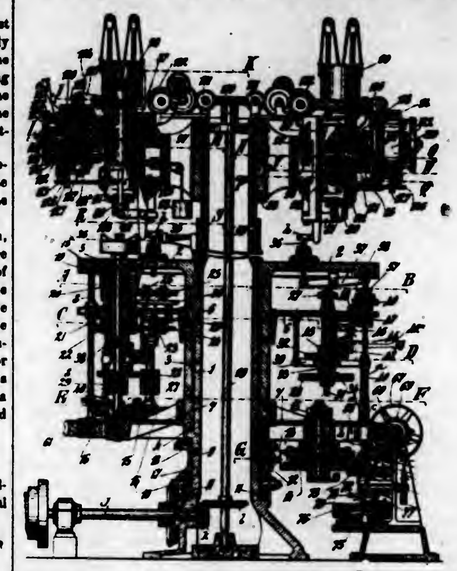
Claim.—1. An apparatus for removing rock and debris, said apparatus comprising drums loosely mounted upon a motor-driven shaft, means for engaging said drums with or disengaging them from the shaft, a rake, a rope extending from the rake to one of said drums, direction-pulleys around which the rope passes, other ropes connecting with opposite sides of the rake, direction-pulleys around which the last-named ropes pass, and independent winding-drums with which said ropes are connected and by which the rake is placed in position.

2. An apparatus for the removal of rocks and debris, said apparatus consisting of a rake, a rope and direction-pulleys by which the rake may be drawn across the territory to be cleared, other ropes attached to the sides of the rake through which power may be applied to transfer the rake to any desired point to embrace the material to be removed.

3. In an apparatus for removing rock and debris, a rake consisting of bent arms having their outer ends adapted to engage the material to be moved, a central shank to which said arms converge and are fixed, a swiveled rope connection carried by the end of the shank, spacing-blocks by which the outer ends of the arms are maintained in position and means for attaching ropes upon opposite sides whereby the device may be moved laterally.

4. In an apparatus for moving rocks and debris, a rake composed of curved arms, adapted to engage the material, a central shank to which said arms converge and are secured, a caster-wheel upon which the shank is supported, a swivel attachment for a rope by which the rake and its load may be moved, spacing-blocks by which the outer ends of the arms are maintained in position, means carried by opposite sides of the rake for the attachment of ropes whereby transverse movement in positioning of the rake may be effected with relation to the material to be moved.

809,594. **SELF-ACTING MULTISPINDLE-MACHINE.** RUDOLF WERNER-ARNOLD, Horgen, Switzerland, assignor to The Firm of Werner & Co., Horgen, Switzerland. Filed Oct. 9, 1903. Serial No. 176,821.



Claim.—1. In a self-acting multispindle-machine, the combination of a number of work-spindles and a rotary frame; of a corresponding number of tool slides or carriages arranged around the axis of the rotary frame, with means to operate each tool separately and independently of the other tools, said means including means for giving the tool a longitudinal feed and means for giving it a transverse feed, controlling means for such feeds adapted to permit the longitudinal feed, the transverse feed or both feeds together relative to the article under treatment.

2. In a self-acting multispindle-machine, the combination of a number of work-spindles and a rotary frame; of a corresponding number of tool slides or carriages arranged around the axis of the rotary frame, with means to operate each tool separately and independently of the other tools, said means including means for giving the tool a longitudinal feed and means for giving it a transverse feed, controlling means for such feeds adapted to permit the longitudinal feed, the transverse feed or both feeds together relative to the article under treatment, means for returning the tool into its initial position after completing its allotted partial machining of the article situated opposite to it.

3. In a self-acting multispindle-machine, the combination of a number of work-spindles and a rotary frame; of a corresponding number of tool slides or carriages arranged around the axis of the rotary frame, with means to operate each tool separately and independently of the other tool, said means including means for giving the tool a longitudinal feed and means for giving it a transverse feed, controlling means for such feeds adapted to permit the longitudinal feed, the transverse feed or both feeds together relative to the article under treatment, means for returning the tool into its initial position after completing its allotted partial machining of the article situated opposite to it, means to rotate the rotary frame relatively to the tools at any desired variable intervals of time, and means adapted to permit said rotation to be utilized for bringing the feed movement of the tools in operation.

4. In a self-acting multispindle-machine, a rotary frame and a number of rotary work-spindles mounted in a circle at equal distances apart in said frame, in combination with a corresponding number of tool slides or carriages arranged around the axis of the rotary frame, with means to operate each tool separately and independently of the other tools, said means including means to give the tool a longitudinal feed and means to give it a transverse feed, controlling means for such feeds adapted to permit the longitudinal feed, the transverse feed or both feeds together relative to the article under treatment, means to return the tool into its initial position after

completing its allotted partial machining of the article situated op-

other tools, each of said mechanisms including means for giving the

completing its allotted partial machining of the article situated opposite to it, means to set the said tool-feeding mechanisms into operation, and means on the frame coacting therewith; a separate mechanism situated outside of the machine and provided with its own driving power for rotating the rotary frame relatively to the tools at any desired variable intervals of time.

5. In a self-acting multispindle-machine, a rotary frame, a number of work-spindles mounted in a circle at equal distances apart in said frame, and a corresponding number of independent tool slides or carriages arranged around the axis of the rotary frame, means to rotate the work-spindles and move each of these spindles in the direction of its length separately and independently of the other work-spindles, and means for reversing the direction of movement of the work-spindles at desired intervals of time.

6. In a self-acting multispindle-machine, a rotary frame and a number of work-spindles mounted therein, in combination with a corresponding number of tool slides or carriages arranged around the axis of the frame, means to yieldingly hold each slide in normal position, means to laterally traverse the slides and against the action of their holding means, a tool-holder in each slide, means to normally hold each tool-holder in raised position, and means to feed each tool-holder toward the work-spindles and against the action of their holding means.

7. In a self-acting multispindle-machine, a rotary frame and a number of work-spindles mounted therein, in combination with a number of tool slides or carriages arranged around the axis of the frame a weight to yieldingly hold each tool-slide in normal position, means to traverse the slides and against the action of the weight, a tool-holder in each slide, a weight to hold each holder away from the work-spindles, and means to feed each tool-holder toward the work-spindles against the action of its respective weight.

8. In a self-acting multispindle-machine, a rotary frame and a number of work-spindles mounted therein, in combination with a number of tool slides or carriages arranged around the axis of the frame, means to yieldingly hold each slide in normal position, mechanism to traverse each slide, a tool-holder, means to normally hold each tool-holder away from the work, mechanism to feed each tool-holder to the work against the action of its holding means, means for setting said mechanisms into operation and means on the frame coacting therewith.

9. In a self-acting multispindle-machine, a rotary frame and a number of work-spindles mounted therein, in combination with a number of tool slides or carriages arranged around the axis of the machine, means on each carriage to traverse the slide, a tool-holder in each slide, means on each carriage to feed the tool-holder, cams on each carriage to control the operation of both of said means, mechanism to drive said means, a device on the table to set said mechanism in operation, and a central driving device common to all of the carriages.

10. In a metal-working machine, a work-spindle, in combination with a tool slide or carriage, said tool-slide containing a spindle, a controlling-cam and a gear-wheel fixed on the spindle, a drum revolubly on the spindle having an external-toothed ring, two slidable pins mounted in the drum and planet-gears having clutch-faces on the pins and a gear-train clutched and operated by each planet-gear, one of said trains capable of traversing the carriage and the other of feeding the tool, said pins operated by the cam, and mechanism to rotate the drum.

11. In a self-acting multispindle-machine, a rotary frame and a number of work-spindles mounted therein, in combination with a number of tool slides or carriages arranged around the axis of the frame, means to yieldingly hold each tool-carriage in normal position, a spindle fixed to the carriage, a controlling-cam and a gear-wheel fixed on the spindle, a tool-holder in each carriage, means to yieldingly hold it away from its work, a drum having an external worm-ring, two slidable pins mounted in the drum, a planet-gear having a clutch-face on each pin and meshing with the gear on the spindle, a gear-train clutched and driven by each planet-gear, one of said trains of gear to traverse the carriage and the other to feed the tool-holder, a continuously-driven worm on each carriage means to move the worm into engagement with the drum by the movement of the rotary frame and a step on the drum to throw said worm out of engagement to permit the carriage and tool-holder to return to normal position.

12. In a multispindle-machine, a pillar, a rotary frame and a friction-ring mounted thereon, a number of work-spindles mounted in the frame, means to drive the friction-ring, means driven by the friction-ring to operate the work-spindles, a corresponding number of tool-slides mounted around the pillar above the frame, with mechanism for operating each tool separately and independently of the other tools, each of said mechanisms including means for giving the tool a longitudinal feed and means for giving it a transverse feed, controlling means for said feeds and a driven element common to all of said mechanisms to drive them.

13. In a self-acting multispindle-machine, a number of work-spindles mounted in a circle at equal distances apart in a rotary frame common to all of them and a corresponding number of independent tool slides or carriages arranged around the axis of the rotary frame, means to rotate the work-spindles and move each of these spindles in the direction of its length separately and independently of the other work-spindles, said means including a friction-drive with driving friction-cylinder, friction-bowls all driven by the friction-cylinder and a worm driving-gear for each work-spindle, the worm-shaft of these gears being freely movable in the direction of its length and adapted to utilize the thrust of the worm-wheel in the direction of the length of the worm-shaft to press the friction-bowls against the driving friction-cylinder with a force which increases with the thrust of the worm-wheel.

14. In a self-acting multispindle-machine, a central pillar, a drum 88 adjustable along the pillar, a number of tool slides or carriages mounted on the drum, with means to operate each tool separately and independently of the other tools, said means including means for giving the tool a longitudinal feed, means for giving it transverse feed, and controlling means for such feeds adapted to permit the longitudinal feed, the transverse feed or both feeds together relative to the article under treatment, and driving mechanism common to all the means to operate the tools, substantially as described.

15. In a multispindle-machine, a pillar, a rotary frame and a driven friction-ring mounted thereon, a number of work-spindles mounted in the frame, a number of tool-slides mounted around the pillar, a gear-wheel mounted on each spindle, separate means to rotate each gear-wheel driven from said ring, a mechanism to feed each spindle toward its tool driven from said spindle, and means on the frame for intermittently engaging said mechanism to set the same in operation.

16. In a self-acting multispindle-machine, a rotary frame, a number of work-spindles mounted in a circle at equal distances apart in said frame, a corresponding number of independent tool slides or carriages arranged around the axis of the rotary frame, means to rotate the work-spindles, a driven friction-ring having oppositely-situated friction-surfaces, friction-bowls and a worm driving-gear for each work-spindle driven by a bowl, the worm-shaft of the gears being freely movable in the direction of its length to contact the driving-bowl with either one of said surfaces, and a mechanism to move each worm-shaft in the direction of the axis to reverse the direction of rotation of the work-spindle at desired intervals of time.

17. In a self-acting multispindle-machine, a number of tool carriages or slides arranged around the axis of the machine, means to operate each tool separately and independently of the other tools, said means including means to give the tool a longitudinal feed and means to give it a transverse feed, controlling means for such feeds adapted to permit the longitudinal feed, the transverse feed or both feeds together relative to the article under treatment, a number of work-holding spindles mounted in said frame, mechanism to rotate said spindles, means to feed the spindles to and from the tools.

18. In a self-acting multispindle-machine, a rotary frame, a number of tool-slides mounted around the axis of the frame, means to operate each tool separately and independently of the other tools and a device on the frame to set the same in operation, said means including means to give the tool a longitudinal feed, and means to give it a transverse feed, controlling means for both of said feeds adapted to permit the longitudinal feed, the transverse feed or both feeds together relative to the article under treatment, a number of work-holding spindles in the frame, means to separately and independently rotate said spindles, mechanism to feed said spindles to and from the tools and means to set said mechanism into operation.

19. In a self-acting multispindle-machine, a rotary frame, a number of tool-slides mounted around the axis of the frame, means to operate each tool separately and independently of the other tools and a device on the frame to set the same in operation, said means including means to give the tool a longitudinal feed, and means to give it a transverse feed, controlling means for both of said feeds adapted to permit the longitudinal feed, the transverse feed or both feeds together relative to the article under treatment, a number of work-holding spindles in the frame, means to separately and independently rotate said spindles, means set in operation by the rotation of the frame to feed said spindles to and from the tools, and mechanism operated by the means to feed each spindle to control its feed independently of the feed of the other spindles.

20. In a self-acting multispindle-machine, a rotary frame, a number of tool-slides mounted around the axis of the frame, means to operate each tool separately and independently of the other tools and a device on the frame to set the same in operation, work-spindles mounted in the frame, a driven friction-ring having two friction-surfaces, a worm, worm-shaft and bowl capable of longitudinal movement, whereby said bowl can engage either of the friction-surfaces, mechanism driven by the worm to rotate the spindles, a loose gear-wheel having a clutch-face driven from its adjacent work-spindle, planet-gearing, a clutch actuated by the rotation of the frame to connect said planet-gearing to the loose gear-wheel, mechanism operated by the planet-gearing to move the worm-shaft and reverse the rotation of the spindle and means to control the number of reversals of rotation of each spindle.

21. In a self-acting multispindle-machine, a rotary frame, a number of tool-slides mounted around the axis of the frame, a number of work-holding spindles in the frame, means to operate each tool separately and independently of the other tools and a device on the frame to set said means in operation, a driven friction-ring having two oppositely-situated inclined friction-surfaces, a worm, a worm-shaft and a bowl on the shaft, a gear-wheel and a long pinion on each spindle, said gear-wheel driven from the worm, a shaft 31 mounted within the frame for each spindle, a loose gear having a clutch-face and a pinion thereon, a disk on shaft 31, a planet-wheel thereon, means to connect the loose gear and disk, a fixed pinion with which said planet-wheel gears, a rod to move the worm-shaft, a lever thereon, means on the planet-wheel to transmit movement to the lever to oscillate the rod, a notched element on the rod and a ratchet-wheel operated by the lever and in slidable engagement with the notched element to disconnect the loose gear.

22. The combination with a central pillar, of a rotary frame thereon, a ring having oppositely-situated friction-surfaces thereon, work-spindles in the frame, mechanism frictionally driven from the ring to rotate and axially move each spindle, controlling means to permit the axial movement of each spindle independently of the others and to determine the number of axial movements thereof to be driven by either one or the other of the friction-surfaces, a drum on the pillar, as many tool-carriages as there are spindles mounted on the drum, means to operate each tool separately and independently of the other tools, means common to all of the tool-operating means to drive the latter, and means on the frame to set said tool-operating means, and the mechanism to rotate the spindles in operation.

23. In a self-acting multispindle-machine, a rotary frame, a peripheral worm-ring thereon, a worm to drive the worm-ring, a continuously-driven shaft in alinement with the worm, a fixed internal-toothed ring, a pinion gearing therewith having an adjustable pin mounted therein, change-gears driven from the shaft to drive the pinion, lever mechanism in the path of said pin to throw the clutch into engagement to operate the worm and means on the frame to throw the clutch out of engagement.

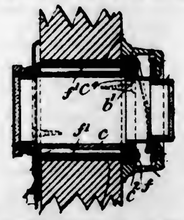
24. In a multispindle-machine, the combination with a pillar, a frame and a driven friction-ring thereon, said ring having oppositely-positioned friction-surfaces; of a work-holding spindle mounted in the frame, a pinion thereon, a worm, worm-shaft and friction-bowl mounted on the frame and longitudinally movable to cause said bowl to contact with either of the friction-surfaces on the ring, gearing connecting the pinion and worm and means to axially move the worm, worm-shaft and bowl at desired intervals of time to change the direction of rotation of the spindle, substantially as set forth.

25. In a multispindle-machine, the combination with a pillar, a rotary frame thereon, a work-holding spindle mounted in the frame and mechanism to rotate the spindle; of mechanism driven by the spindle and means on the frame to set the mechanism in operation when the frame rotates to feed the work-holding spindle longitudinally.

26. In a multispindle-machine, the combination with a pillar, a rotary frame, indexing mechanism therefor, a work-holding spindle mounted in the frame to have both longitudinal and rotary motion, and a continuously-driven friction-ring on the pillar below the frame having oppositely-situated friction-surfaces; of a pinion through which the spindle can slide but not rotate, a long pinion fixed on the spindle, a worm, worm-shaft and bowl on the worm-shaft, gearing connecting said first-named pinion and worm to rotate the spindle, an idle clutch-wheel driven by the long pinion, mechanism clutched into gear with the idle wheel to feed the work-holding spindle in a longitudinal direction, including means to automatically reverse the feed of the spindle, and means to control the number of reversals both of the feed and the rotation of the spindle, substantially as described.

27. In a multispindle-machine, the combination with a pillar, a rotary frame, indexing mechanism therefor, a work-holding spindle mounted to rotate and longitudinally move in the frame, a screw on the spindle and a rotatable nut on the screw; of a worm, worm-shaft and bowl on the worm-shaft, a two-part rod capable of oscillation connected to the worm-shaft, the upper part of said rod longitudinally movable, gearing connecting the spindle and worm, a vertical shaft mounted in the frame, an idle clutch gear-wheel driven from the spindle, planet-gearing, a fixed element on the pillar, a lever to depress the upper part of said two-part rod and operated from the fixed element during the indexing of the frame, planet-gearing mounted on the vertical shaft to oscillate the rod, a clutch member between it and the idle gear-wheel, operated by the upper part of said rod, gearing connecting the vertical shaft and rotatable nut, and means on the rod actuated from the planet-gearing to control the number of oscillations of the rod and thereby the number of reversals of the spindle, substantially as and for the purposes set forth.

809,595. BELL PUSH, PULL, &c. LAWRENCE S. WILES, Whippa Cross, England. Filed May 1, 1905. Serial No. 258,334.



Claim.—1. In means for illuminating bell-actuating devices, a hole or way through the object to which the device is affixed, a tubular movable hand-operated device in alinement with said hole at the front thereof, a disk of a material which will allow the passage of light at the front end of said tubular device, a similar disk at the near end of said hole and means actuated by said tubular device for sounding a bell, substantially as described.

2. In means for illuminating bell-actuating devices, a hole or way through the object to which the device is affixed, a tubular movable hand-operated device in alinement with said hole at the front thereof, a disk of a material which will allow the passage of light at the front end of said tubular device, a similar disk at the rear end of said hole, electric contacts adapted to be brought into engagement by the movement of the tubular device and means for connecting the leads of an electric-bell system with said contacts, substantially as described.

3. In means for illuminating bell-actuating devices, a hole or way through the object to which the device is affixed, a tubular movable hand-operated device in alinement with said hole at the front thereof, a disk of a material which will allow the passage of light in the front end of said tubular device, a similar disk at the rear end of the hole or way, an insulating-ring carrying electrical contact devices adapted to be brought into engagement by the movement of the tubular device, means for connecting the leads of an electric-bell system with said contacts, a screw-thread upon the exterior of the insulating-ring, a flange upon the tubular device, an insulating-washer upon the inner face of said flange and means for inclosing said parts while exposing the transparent or translucent disk of the tubular device, substantially as described.

4. In means for illuminating bell-actuating devices, a hole or way through the object to which the device is affixed, a tubular push-piece in alinement with said hole at the front thereof, a disk of a material which will allow the passage of light in the front end of said push-piece, a similar disk at the rear end of said hole or way, an insulating-ring fixed with said object and carrying electrical contact devices adapted to be brought into engagement by the movement of the push-piece, means for connecting the leads of an electric-bell system with said contacts, a screw-thread upon the exterior of the insulating-ring, a flange upon the tubular push-piece, an insulating-washer upon the inner face of said flange and a perforated cap fitting upon the push-piece and screwing upon the insulating-ring, substantially as described.

5. In means for illuminating bell-actuating devices, a hole or way through the object to which the device is affixed, a length of tube passing through said hole, a tubular push-piece working in the front end of said tube, a disk of a material which will allow the pas-

completing its allotted partial machining of the article situated opposite to it, means to set the said tool-feeding mechanisms into operation, and means on the frame connting therewith; a separate mechanism situated outside of the machine and provided with its own driving power for rotating the rotary frame relatively to the tools at any desired variable intervals of time.

5. In a self-acting multispindle-machine, a rotary frame, a number of work-spindles mounted in a circle at equal distances apart in said frame, and a corresponding number of independent tool slides or carriages arranged around the axis of the rotary frame, means to rotate the work-spindles and move each of these spindles in the direction of its length separately and independently of the other work-spindles, and means for reversing the direction of movement of the work-spindles at desired intervals of time.

6. In a self-acting multispindle-machine, a rotary frame and a number of work-spindles mounted therein, in combination with a corresponding number of tool slides or carriages arranged around the axis of the frame, means to yieldingly hold each slide in normal position, means to laterally traverse the slides and against the action of their holding means, a tool-holder in each slide, means to normally hold each tool-holder in raised position, and means to feed each tool-holder toward the work-spindles and against the action of their holding means.

7. In a self-acting multispindle-machine, a rotary frame and a number of work-spindles mounted therein, in combination with a number of tool slides or carriages arranged around the axis of the frame a weight to yieldingly hold each tool-slide in normal position, means to traverse the slides and against the action of the weight, a tool-holder in each slide, a weight to hold each holder away from the work-spindles, and means to feed each tool-holder toward the work-spindles against the action of its respective weight.

8. In a self-acting multispindle-machine, a rotary frame and a number of work-spindles mounted therein, in combination with a number of tool slides or carriages arranged around the axis of the frame, means to yieldingly hold each slide in normal position, mechanism to traverse each slide, a tool-holder, means to normally hold each tool-holder away from the work, mechanism to feed each tool-holder to the work against the action of its holding means, means for setting said mechanisms into operation and means on the frame connting therewith.

9. In a self-acting multispindle-machine, a rotary frame and a number of work-spindles mounted therein, in combination with a number of tool slides or carriages arranged around the axis of the machine, means on each carriage to traverse the slide, a tool-holder in each slide, means on each carriage to feed the tool-holder, cams on each carriage to control the operation of both of said means, mechanism to drive said means, a device on the table to set said mechanism in operation, and a central driving device common to all of the carriages.

10. In a metal-working machine, a work-spindle, in combination with a tool slide or carriage, said tool-slide containing a spindle, a controlling-cam and a gear-wheel fixed on the spindle, a drum revoluble on the spindle having an external-toothed ring, two slidable pins mounted in the drum and planet-gears having clutch-faces on the pins and a gear-train clutched and operated by each planet-gear, one of said trains capable of traversing the carriage and the other of feeding the tool, said pins operated by the cam, and mechanism to rotate the drum.

11. In a self-acting multispindle-machine, a rotary frame and a number of work-spindles mounted therein, in combination with a number of tool slides or carriages arranged around the axis of the frame, means to yieldingly hold each tool-carriage in normal position, a spindle fixed to the carriage, a controlling-cam and a gear-wheel fixed on the spindle, a tool-holder in each carriage, means to yieldingly hold it away from its work, a drum having an external worm-ring, two slidable pins mounted in the drum, a planet-gear having a clutch-face on each pin and meshing with the gear on the spindle, a gear-train clutched and driven by each planet-gear, one of said trains of gear to traverse the carriage and the other to feed the tool-holder, a continuously-driven worm on each carriage means to move the worm into engagement with the drum by the movement of the rotary frame and a stop on the drum to throw said worm out of engagement to permit the carriage and tool-holder to return to normal position.

12. In a multispindle-machine, a pillar, a rotary frame and a friction-ring mounted thereon, a number of work-spindles mounted in the frame, means to drive the friction-ring, means driven by the friction-ring to operate the work-spindles, a corresponding number of tool-slides mounted around the pillar above the frame, with mechanisms for operating each tool separately and independently of the other tools, each of said mechanisms including means for giving the tool a longitudinal feed and means for giving it a transverse feed, controlling means for said feeds and a driven element common to all of said mechanisms to drive them.

13. In a self-acting multispindle-machine, a number of work-spindles mounted in a circle at equal distances apart in a rotary frame common to all of them and a corresponding number of independent tool slides or carriages arranged around the axis of the rotary frame, means to rotate the work-spindles and move each of these spindles in the direction of its length separately and independently of the other work-spindles, said means including a friction-drive with driving friction-cylinder, friction-bowls all driven by the friction-cylinder and a worm driving-gear for each work-spindle, the worm-shaft of these gears being freely movable in the direction of its length and adapted to utilize the thrust of the worm-wheel in the direction of the length of the worm-shaft to press the friction-bowls against the driving friction-cylinder with a force which increases with the thrust of the worm-wheel.

14. In a self-acting multispindle-machine, a central pillar, a drum 88 adjustable along the pillar, a number of tool slides or carriages mounted on the drum, with means to operate each tool separately and independently of the other tools, said means including means for giving the tool a longitudinal feed, means for giving it transverse feed, and controlling means for such feeds adapted to permit the longitudinal feed, the transverse feed or both feeds together relative to the article under treatment, and driving mechanism common to all the means to operate the tools, substantially as described.

15. In a multispindle-machine, a pillar, a rotary frame and a driven friction-ring mounted thereon, a number of work-spindles mounted in the frame, a number of tool-slides mounted around the pillar, a gear-wheel mounted on each spindle, separate means to rotate each gear-wheel driven from said ring, a mechanism to feed each spindle toward its tool driven from said spindle, and means on the frame for intermittently engaging said mechanism to set the same in operation.

16. In a self-acting multispindle-machine, a rotary frame, a number of work-spindles mounted in a circle at equal distances apart in said frame, a corresponding number of independent tool slides or carriages arranged around the axis of the rotary frame, means to rotate the work-spindles, a driven friction-ring having oppositely-situated friction-surfaces, friction-bowls and a worm driving-gear for each work-spindle driven by a bowl, the worm-shaft of the gears being freely movable in the direction of its length to contact the driving-bowl with either one of said surfaces, and a mechanism to move each worm-shaft in the direction of the axis to reverse the direction of rotation of the work-spindle at desired intervals of time.

17. In a self-acting multispindle-machine, a number of tool carriages or slides arranged around the axis of the machine, means to operate each tool separately and independently of the other tools, said means including means to give the tool a longitudinal feed and means to give it a transverse feed, controlling means for such feeds adapted to permit the longitudinal feed, the transverse feed or both feeds together relative to the article under treatment, a rotary frame, a number of work-holding spindles mounted in said frame, mechanism to rotate said spindles, means to feed the spindles to and from the tools.

18. In a self-acting multispindle-machine, a rotary frame, a number of tool-slides mounted around the axis of the frame, means to operate each tool separately and independently of the other tools and a device on the frame to set the same in operation, said means including means to give the tool a longitudinal feed, and means to give it a transverse feed, controlling means for both of said feeds adapted to permit the longitudinal feed, the transverse feed or both feeds together relative to the article under treatment, a number of work-holding spindles in the frame, means to separately and independently rotate said spindles, mechanism to feed said spindles to and from the tools and means to set said mechanism into operation.

19. In a self-acting multispindle-machine, a rotary frame, a number of tool-slides mounted around the axis of the frame, means to operate each tool separately and independently of the other tools and a device on the frame to set the same in operation, said means including means to give the tool a longitudinal feed, and means to give it a transverse feed, controlling means for both of said feeds adapted to permit the longitudinal feed, the transverse feed or both feeds together relative to the article under treatment, a number of work-holding spindles in the frame, means to separately and independently rotate said spindles, means set in operation by the rotation of the frame to feed said spindles to and from the tools, and mechanism operated by the means to feed each spindle to control its feed independently of the feed of the other spindles.

20. In a self-acting multispindle-machine, a rotary frame, a number of tool-slides mounted around the axis of the frame, means to operate each tool separately and independently of the other tools and a device on the frame to set the same in operation, work-spindles mounted in the frame, a driven friction-ring having two friction-surfaces, a worm, worm-shaft and bowl capable of longitudinal movement, whereby said bowl can engage either of the friction-surfaces, mechanism driven by the worm to rotate the spindles, a loose gear-wheel having a clutch-face driven from its adjacent work-spindle, planet-gearing, a clutch actuated by the rotation of the frame to connect said planet-gearing to the loose gear-wheel, mechanism operated by the planet-gearing to move the worm-shaft and reverse the rotation of the spindle and means to control the number of reversals of rotation of each spindle.

21. In a self-acting multispindle-machine, a rotary frame, a number of tool-slides mounted around the axis of the frame, a number of work-holding spindles in the frame, means to operate each tool separately and independently of the other tools and a device on the frame to set said means in operation, a driven friction-ring having two oppositely-situated inclined friction-surfaces, a worm, a worm-shaft and a bowl on the shaft, a gear-wheel and a long pinion on each spindle, said gear-wheel driven from the worm, a shaft 31 mounted within the frame for each spindle, a loose gear having a clutch-face and a pinion thereon, a disk on shaft 31, a planet-wheel thereon, means to connect the loose gear and disk, a fixed pinion with which said planet-wheel gears, a rod to move the worm-shaft, a lever thereon, means on the planet-wheel to transmit movement to the lever to oscillate the rod, a notched element on the rod and a ratchet-wheel operated by the lever and in slidable engagement with the notched element to disconnect the loose gear.

22. The combination with a central pillar, of a rotary frame thereon, a ring having oppositely-situated friction-surfaces thereon, work-spindles in the frame, mechanism frictionally driven from the ring to rotate and axially move each spindle, controlling means to permit the axial movement of each spindle independently of the others and to determine the number of axial movements thereof to be driven by either one or the other of the friction-surfaces, a drum on the pillar, as many tool-carriages as there are spindles mounted on the drum, means to operate each tool separately and independently of the other tools, means common to all of the tool-operating means to drive the latter, and means on the frame to set said tool-operating means, and the mechanism to rotate the spindles in operation.

23. In a self-acting multispindle-machine, a rotary frame, a peripheral worm-ring thereon, a worm to drive the worm-ring, a continuously-driven shaft in alinement with the worm, a fixed internal-toothed ring, a pinion gearing therewith having an adjustable pin mounted therein, change-gears driven from the shaft to drive the pinion, lever mechanism in the path of said pin to throw the clutch into engagement to operate the worm and means on the frame to throw the clutch out of engagement.

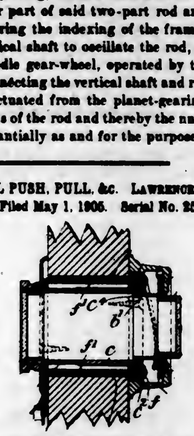
24. In a multispindle-machine, the combination with a pillar, a frame and a driven friction-ring thereon, said ring having oppositely-positioned friction-surfaces; of a work-holding spindle mounted in the frame, a pinion thereon, a worm, worm-shaft and friction-bowl mounted on the frame and longitudinally movable to cause said bowl to contact with either of the friction-surfaces on the ring, gearing connecting the pinion and worm and means to axially move the worm, worm-shaft and bowl at desired intervals of time to change the direction of rotation of the spindle, substantially as set forth.

25. In a multispindle-machine, the combination with a pillar, a rotary frame thereon, a work-holding spindle mounted in the frame and mechanism to rotate the spindle; of mechanism driven by the spindle and means on the frame to set the mechanism in operation when the frame rotates to feed the work-holding spindle longitudinally.

26. In a multispindle-machine, the combination with a pillar, a rotary frame, indexing mechanism therefor, a work-holding spindle mounted in the frame to have both longitudinal and rotary motion, and a continuously-driven friction-ring on the pillar below the frame having oppositely-situated friction-surfaces; of a pinion through which the spindle can slide but not rotate, a long pinion fixed on the spindle, a worm, worm-shaft and bowl on the worm-shaft, gearing connecting said first-named pinion and worm to rotate the spindle, an idle clutch-wheel driven by the long pinion, mechanism clutched into gear with the idle wheel to feed the work-holding spindle in a longitudinal direction, including means to automatically reverse the feed of the spindle, and means to control the number of reversals both of the feed and the rotation of the spindle, substantially as described.

27. In a multispindle-machine, the combination with a pillar, a rotary frame, indexing mechanism therefor, a work-holding spindle mounted to rotate and longitudinally move in the frame, a screw on the spindle and a rotatable nut on the screw; of a worm, worm-shaft and bowl on the worm-shaft, a two-part rod capable of oscillation connected to the worm-shaft, the upper part of said rod longitudinally movable, gearing connecting the spindle and worm, a vertical shaft mounted in the frame, an idle clutch gear-wheel driven from the spindle, planet-gearing, a fixed element on the pillar, a lever to depress the upper part of said two-part rod and operated from the fixed element during the indexing of the frame, planet-gearing mounted on the vertical shaft to oscillate the rod, a clutch member between it and the idle gear-wheel, operated by the upper part of said rod, gearing connecting the vertical shaft and rotatable nut, and means on the rod actuated from the planet-gearing to control the number of oscillations of the rod and thereby the number of reversals of the spindle, substantially as and for the purposes set forth.

809,595. BELL PUSH, PULL, &c. LAWRENCE S. WILKS, Whippa Cross, England. Filed May 1, 1905. Serial No. 258,334.



Claim.—1. In means for illuminating bell-actuating devices, a hole or way through the object to which the device is affixed, a tubular movable hand-operated device in alinement with said hole at the front thereof, a disk of a material which will allow the passage of light at the front end of said tubular device, a similar disk at the rear end of said hole and means actuated by said tubular device for sounding a bell, substantially as described.

2. In means for illuminating bell-actuating devices, a hole or way through the object to which the device is affixed, a tubular movable hand-operated device in alinement with said hole at the front thereof, a disk of a material which will allow the passage of light at the front end of said tubular device, a similar disk at the rear end of said hole, electric contacts adapted to be brought into engagement by the movement of the tubular device and means for connecting the leads of an electric-bell system with said contacts, substantially as described.

3. In means for illuminating bell-actuating devices, a hole or way through the object to which the device is affixed, a tubular movable hand-operated device in alinement with said hole at the front thereof, a disk of a material which will allow the passage of light in the front end of said tubular device, a similar disk at the rear end of the hole or way, an insulating-ring carrying electrical contact devices adapted to be brought into engagement by the movement of the tubular device, means for connecting the leads of an electric-bell system with said contacts, a screw-thread upon the exterior of the insulating-ring, a flange upon the tubular device, an insulating-washer upon the inner face of said flange and means for inclosing said parts while exposing the transparent or translucent disk of the tubular device, substantially as described.

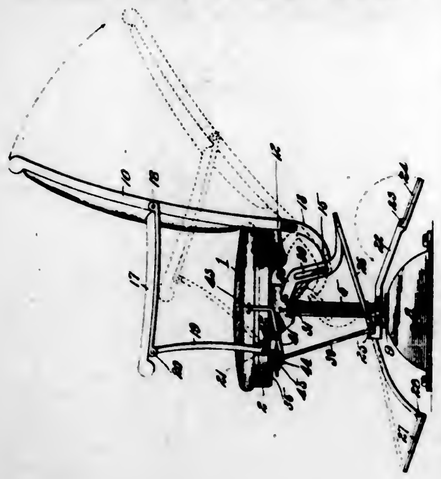
4. In means for illuminating bell-actuating devices, a hole or way through the object to which the device is affixed, a tubular push-piece in alinement with said hole at the front thereof, a disk of a material which will allow the passage of light in the front end of said push-piece, a similar disk at the rear end of said hole or way, an insulating-ring fixed with said object and carrying electrical contact devices adapted to be brought into engagement by the movement of the push-piece, means for connecting the leads of an electric-bell system with said contacts, a screw-thread upon the exterior of the insulating-ring, a flange upon the tubular push-piece, an insulating-washer upon the inner face of said flange and a perforated cap fitting upon the push-piece and screwing upon the insulating-ring, substantially as described.

5. In means for illuminating bell-actuating devices, a hole or way through the object to which the device is affixed, a length of tube passing through said hole, a tubular push-piece working in the front end of said tube, a disk of a material which will allow the pas-

cage of light in the front end of said push-piece, a similar disk at the rear end of said tube, an insulating-ring screwing into the front end of the tube and carrying electrical contact devices adapted to be brought into engagement by the movement of the push-piece, means for connecting the leads of an electric-bell system with said contacts, a screw-thread upon the exterior of the insulating-ring, a flange upon the tubular push-piece, an insulating-washer upon the inner face of said flange and a perforated cap fitting upon the push-piece and screwing upon the insulating-ring, substantially as described.

6. In means for illuminating bell-actuating devices, a tubular push-piece arranged within one end of a hole or way through the object to which the device is attached, said push and opposite end of said hole or way each being furnished with a disk of material which will allow of the passage of light, substantially as described.

809,596. **REVOLVING AND RECLINING CHAIR.** HUBERT WITTE, St. Louis, Mo., assignor to St. Louis Car Company, St. Louis, Mo., a Corporation. Filed July 7, 1905. Serial No. 268,650.



Claim.—1. In a chair of the character described, the combination of a seat, a post by which said seat is supported, a swingingly-supported chair-back, a foot-rest arm fixed to said post, and a reciprocating foot-rest member loosely connected to said chair-back and operating in said foot-rest arm, substantially as set forth.

2. In a chair of the character described, the combination of a seat, a post by which said seat is supported, a chair-back swingingly supported, a link having pivotal connection with said seat and loosely fitted to said chair-back, a foot-rest arm fixed to said post and provided with eyes, and a reciprocating foot-rest member loosely connected to said link and operating in the eyes of said foot-rest, substantially as set forth.

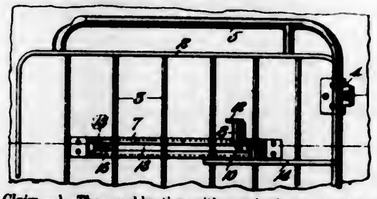
3. In a chair of the character described, the combination of a seat, a post by which said seat is supported, a chair-back swingingly supported, a link having pivotal connection with said seat and loosely fitted to said chair-back, a foot-rest arm fixed to said post, and a reciprocating foot-rest member loosely connected to said link and operating in said foot-rest arm, substantially as set forth.

4. In a chair of the character described, the combination of a seat, a post by which said seat is supported, a chair-back swingingly supported, a link having pivotal connection with said seat and loosely fitted to said chair-back, a foot-rest arm fixed to said post, a reciprocating foot-rest member loosely connected to said link and operating in said foot-rest arm, and a rack-bar connected to said chair-back and arranged to hold said back and link from movement, substantially as set forth.

5. In a chair of the character described, the combination of a seat, a chair-back swingingly connected to said seat, a slotted link having pivotal connection with said seat, and a reciprocating foot-rest member pivoted to said link, said chair-back being provided with an arm having a gudgeon operating in the slot in said link, substantially as set forth.

7. In a chair of the character described, the combination of a seat, a chair-back swingingly connected to said seat, a slotted link having pivotal connection with said seat, a reciprocating foot-rest member pivoted to said link, said chair-back being provided with an arm having a gudgeon operating in the slot in said link; and a rack-bar pivoted to said chair-back arm and arranged to hold it from movement, substantially as set forth.

809,597. **CAR-PLATFORM GATE.** HUBERT WITTE, St. Louis, Mo., assignor to St. Louis Car Company, St. Louis, Mo., a Corporation. Filed Oct. 19, 1905. Serial No. 283,289.



Claim.—1. The combination with a swinging gate, of a guide, a link connected to said gate and arranged to operate in said guide, and a retaining-bolt supported by said guide and arranged to engage said link, substantially as set forth.

2. The combination with a swinging gate, of a link connected to said gate, a guide in which said link operates and a spring retaining-bolt carried by said guide, substantially as set forth.

3. The combination with a swinging gate, of a guide, of a link connected to said gate and provided with a tooth, and a retaining-bolt arranged to engage said tooth; said link being arranged to operate in said guide, substantially as set forth.

4. The combination with a swinging gate, of a channel-guide, a link pivoted to said gate and provided with studs arranged to operate in the channel in said guide, and a retaining-bolt arranged to engage said link to hold it from movement in said guide; said link being provided with a tooth to be engaged by said retaining-bolt, substantially as set forth.

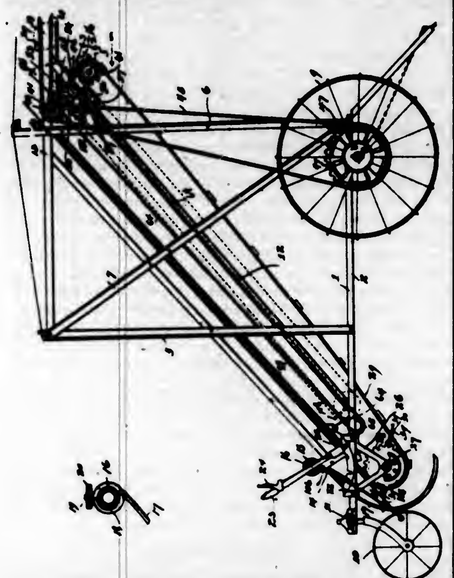
809,598. **HAY-LOADER.** SAMUEL M. WILKIE, Marcus, Iowa. Filed Apr. 13, 1905. Serial No. 255,422.

Claim.—1. In a hay-loader, the combination with a portable frame, of an elevating-carrier, a coöperating extendible and retractable carrier, driving connections for operating said carriers during the movement of said frame, and mechanism for automatically reversing the extending and retracting movement of said horizontal carrier during operation.

2. In a hay-loader, the combination with a portable frame, of an endless elevating and delivering carrier moving thereon, one portion thereof inclined and the other portion thereof substantially horizontal, mechanism for automatically extending and retracting the horizontal portion longitudinally, and mechanism for automatically actuating said carrier during the movement of said frame.

3. In a hay-loader, the combination with a portable frame, of an endless elevating and delivering carrier moving upon said frame, one portion thereof inclined and the other portion thereof substantially horizontal, said horizontal portion adapted to be automatically extended and retracted longitudinally during the movement of said frame and carrier, driving connections for actuating said carrier, and mechanism for automatically reversing the extending and retracting movement of the horizontal portion of said carrier during its operation.

4. In a hay-loader, the combination with a portable frame, of an elevating-carrier, a coöperating delivery-carrier adapted to be extended and contracted, mechanism for automatically extending and retracting said delivery-carrier during operation, driving connections for actuating said carrier, and a floating guard-frame overlying said elevating-carrier and yieldingly retaining the hay thereupon during its upward movement.



5. In a hay-loader, the combination of a main wheeled frame, a rake suspended therefrom, an inclined elevating-carrier frame portion, a horizontal carrier-frame portion connected with the upper part of said inclined frame portion, an endless carrier traveling upon said inclined and horizontal frame portions, mechanism for telescoping said carrier within itself to extend and retract the delivery end thereof, and mechanism for actuating the carrier.

6. In a hay-loader, the combination with a main wheeled frame comprising an inclined carrier-frame portion and a horizontal extension connected with the upper end thereof, of an endless carrier mounted to travel upon said frame and extension, a support for the delivery end of said carrier mounted to reciprocate longitudinally on the horizontal extension of the frame, mechanism for automatically reciprocating and reversing the movement of said support, and mechanism for actuating said carrier.

7. In a hay-loader, the combination of a main wheeled frame comprising upwardly-inclined guides and horizontally-disposed guides at the upper ends of said inclined guides, a carrier-support at the receiving end of the carrier, a movable carrier-support mounted to reciprocate upon said horizontally-disposed guides and supporting the delivery end of the carrier, an intermediate carrier-support mounted to reciprocate upon the inclined guides, an endless carrier trained around said several supports, mechanism for holding said movable supports in various positions of adjustment, and mechanism for operating the endless carrier.

8. In a hay-loader, the combination of a main wheeled frame comprising upwardly-inclined guides and horizontally-disposed guides at the upper ends of said inclined guides, a carrier-support at the receiving end of the carrier, a movable carrier-support mounted to reciprocate upon said horizontally-disposed guides and supporting the delivery end of the carrier, an intermediate carrier-support mounted to reciprocate upon the inclined guides, an endless carrier trained around said several supports, mechanism for holding said movable supports in various positions of adjustment, mechanism for operating the endless carrier, comprising mechanism for imparting a determined rate of travel to one portion of the carrier, and mechanism for imparting a different rate of travel to another portion of the carrier, for the purpose set forth.

9. In a hay-loader, the combination of a main wheeled frame, a rake suspended at the rear end of said frame, an inclined carrier-frame extending from the rake upwardly and forwardly, a horizontal frame extension connected with the upper end of the inclined frame portions, an endless carrier supported upon said inclined and horizontal frame portions, a bodily-shiftable carrier-support mounted to reciprocate upon the horizontal frame extension and supporting the delivery end of said carrier, a take-up carrier-support movably mounted to reciprocate upon the inclined frame portion and engaging with the intermediate portion of the endless carrier, tension-cable and guide-pulley connections between said movable intermediate carrier-support and said movable delivery end carrier-support, and driving connections for actuating said carrier.

10. In a hay-loader, the combination of a main wheeled supporting-frame, a rake operatively supported from the rear end of said frame, a rotatable carrier-support located in proximity to said rake, a horizontal frame extension connected with the upper part of the main frame, rotatable carrier-supports located at or near the junction of the horizontal frame extension with the main frame but spaced apart vertically, a rotatable carrier-support shiftably mounted upon the horizontal frame extension, an endless carrier trained around said several specified supports, a pair of inclined guides located at the respective sides of the carrier and between the upper and lower laps of the inclined portions thereof, an intermediate carrier-support mounted to reciprocate bodily upon said inclined guides and around which the looped back intermediate portion of the carrier extends, driving connections from one of the main supporting-wheels to one of said carrier-supports engaged with, and supporting one of the outer laps of the endless carrier, driving connections to a carrier-support engaging the intermediate or looped back portion of the carrier, and means for throwing said second driving connections out of gear, as and for the purpose set forth.

11. In a hay-loader, the combination of a wheeled main frame comprising lower horizontal side-bar members, cross-frame members connecting said side-bar members, a pair of vertical uprights at each side and spaced apart longitudinally, horizontal extension side-frame members connected with said uprights at the upper ends of the latter and extending forward freely beyond said uprights, the projecting portions of said upper horizontal side-frame members being provided with ways to constitute guides, inclined guide-frame members provided with ways, extending from the intermediate portions of the upper guide members obliquely downwardly and rearwardly to the lower horizontal frame, a rake operatively suspended from the rear end of said main frame, a lower carrier-support rotatably supported in proximity to said rake and in alinement with said inclined guide members, transversely opposite rotatable carrier-supports located respectively above and below said inclined guides and adjacent to the junction of the guides with the upper horizontal guide members, the shaft of one of said carrier-supports constituting the main drive-shaft, an intermediate carrier-support mounted to reciprocate upon said inclined guides, a carrier-support mounted to reciprocate upon the horizontal guide-frame members and constituting a support for the delivery end of the carrier, an endless carrier trained around said several supports, substantially as described, driving connections from one of the supporting-wheels of the loader to said main shaft, driving connections from said main shaft to the transversely opposite carrier-support, a carrier-support engaging and supporting the lower lap of the horizontal extendible portion of the carrier at the juncture of said horizontal extendible portion with the inclined portion of the carrier, change-speed driving connections between said main shaft and the latter carrier-support, an automatically-acting mechanism for alternately throwing said change-speed mechanism into gear and locking it against rotation.

12. In a hay-loader, the combination of a wheeled main frame comprising lower horizontal side-bar members, cross-frame members connecting said side-bar members, a pair of vertical uprights at each side and spaced apart longitudinally, horizontal extension side-frame members connected with said uprights at the upper ends of the latter and extending forward freely beyond said uprights, the projecting portions of said upper horizontal side-frame members being provided with ways to constitute guides, inclined guide-frame members provided with ways extending from the intermediate portions of the upper guide members obliquely downwardly and rearwardly to the lower horizontal frame, a rake operatively suspended from the rear end of said main frame, a lower carrier-support rotatably supported in proximity to said rake and in alinement with said inclined guide members, transversely opposite rotatable carrier-supports located respectively above and below said inclined guides and adjacent to the junction of the guides with the upper horizontal guide members, the shaft of one of said carrier-supports constituting the main drive-shaft, an intermediate carrier-support mounted to reciprocate upon said inclined guides, a carrier-support mounted to reciprocate upon the horizontal guide-frame members and constituting a support for the delivery end of the carrier, an endless car-

rier trained around said several supports, substantially as described, driving connections from one of the supporting-wheels of the loader to said main shaft, driving connections from said main shaft to the transversely opposite carrier-support, a carrier-support engaging and supporting the lower lap of the horizontal extendible portion of the carrier at the juncture of said horizontal extendible portion with the inclined portion of the carrier, change-speed driving connections between said main shaft and the latter carrier-support, automatically-acting mechanism for alternately throwing said change-speed mechanism into gear and locking it against rotation, and tension-cables connected with the carrier-support bodily movable on the inclined guides, extending thence around pulleys located on the lower parts of said inclined guides, thence over intermediate guides and around pulleys located at the ends of the horizontal guide-frame members and thence to and connected with the bodily-movable carrier-support traveling upon said horizontal guide-frame members.

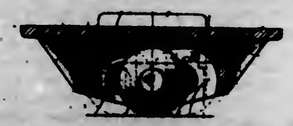
13. In a hay-loader, the combination with a portable frame provided with rake-teeth, of an elevating-carrier, a coöperating extendible and retractable carrier, mechanism for automatically operating and reversing the bodily movement of said carrier; a pair of carrier-supporting wheels located upon said frame in front of and in proximity to said rake-teeth, a plurality of rock-shafts extending between the peripheral portions of said carrier-supporting wheels, each provided with a series of radially-extending pick-up fingers, cranks upon said rock-bars provided with cam-engaging portions, and a fixed cam adjacent to the path of travel of said cranks whereby a variable movement of the rock-bar is imparted during the rotation of the rock-bar-carrying wheels, substantially as described.

14. In combination with a wheeled trailer-frame provided with supporting-wheels and an axle rotatable therewith, of an automatic hitching mechanism comprising a winding-drum mounted upon said axle, a traction-cable engaging said winding-drum, driving connections between the axle and the winding-drum, an automatic throw-off for disengaging said driving connections at a predetermined time, and an automatic dogging mechanism for preventing the unwinding of the cable and which is brought into action when the winding-drum is thrown out of gear.

15. In combination with a wheeled trailer-frame provided with supporting-wheels and an axle rotatable therewith, of an automatic hitching mechanism comprising a winding-drum, mounted upon said axle, a traction-cable engaging said winding-drum, driving connections between the axle and the winding-drum, means for imparting a longitudinal travel of a part upon said axle proportionate to the number of revolutions of the axle, a clutch mechanism constituting a driving connection between axle and the winding-drum, and operative connections between said traveling member and clutch mechanism whereby the latter is thrown out of gear at the end of a predetermined time.

16. In combination with a wheeled trailer-frame provided with supporting-wheels and a shaft rotatable therewith, a sleeve rotatable upon said shaft, a clutch having splined engagement with the shaft and adapted to interengage with the sleeve to lock the latter against rotation, a winding-drum splined upon the sleeve and provided with an external screw-thread, a fixed support with which said screw-thread is interengaged and whereby a longitudinal movement of the drum is imparted by the rotation of the latter, a traction-cable connected with the drum, and a dogging mechanism operating to automatically engage and hold the traction-cable from unwinding when the drum is released; said clutch mechanism being located in the path of travel of the drum, whereby the clutch is disengaged at the end of a predetermined number of revolutions of the drum.

809,599. **ROLLER SIDE BEARING FOR RAILWAY-CARS.** Henry S. Woods, Chicago, Ill. Filed June 16, 1905. Serial No. 265,562.



Claim.—1. In a roller-bearing for railway-cars, an elongated chambered casting formed with integral side and end walls and open at its bottom, the side walls being provided on their inner faces with inwardly-opening channels or ways, a roller mounted in said casting and adapted to project through the open bottom thereof for contact with a lower bearing-surface, and provided with end bearings or trunnions which enter said channels and made of a diameter less than the vertical width of the channels, and an elongated bearing-plate in the top of the casting, one of said end walls being provided with an opening through which the plate is admitted longitudinally to the chambered casting, and the said wall of the casting, at the margin of said admission-opening, being upset against the end of the bearing-plate to constitute a stop to hold the latter in place.

2. In a roller-bearing for railway-cars, an elongated chambered casting formed with integral top, side and end walls and open at its bottom, the side walls being provided on their inner faces with inwardly-opening channels or ways, a roller mounted in said casting and adapted to project through the open bottom thereof for contact with a lower bearing-surface and provided with end bearings or trunnions which enter said channels and made of a diameter less than the vertical width of said channels, and an elongated bearing-plate fitted to the lower face of the top wall of the casting, one of the end walls of the casting being provided with an opening through which the plate is admitted longitudinally to the chambered casting, and the casting being provided with a ledge between which and the top of the casting is received a margin of the bearing-plate the said end wall of the casting at said admission-opening being upset against the end of said plate to constitute a stop to hold the plate in place.

3. In a roller-bearing for railway-cars, an elongated chambered casting provided with a downwardly-facing bearing-surface and formed with integral side and end walls and open at its bottom, the side walls being provided on their inner faces with inwardly-opening channels or ways, and a roller mounted in said chambered casting and adapted to project through said open bottom for contact with a lower bearing-surface, said roller being provided with end bearings or trunnions which enter said channels or ways and made of a diameter less than the vertical width of said channels, the end walls of the casting being curved complementally to the cylindric surface of the roller and serving as stops to engage and arrest the travel of the roller endwise of said bearing-casting.

809,600. **SEWING-MACHINE.** William M. Ahnebrink, New Haven, Conn., assignor to The Edwin J. Toof Company, New Haven, Conn., a Corporation of New Jersey. Filed Oct. 7, 1904. Serial No. 227,536.

Claim.—1. In a sewing-machine, the combination with a rotary loop-taker, of a non-rotary body portion supported in position with a thread-receiving space between it and said loop-taker and also having means for directing one side of a thread-loop engaged by the loop-taker into said thread-receiving space, and a forked loop-holder attached to said body portion and also having connection with the loop-taker to be movable therewith.

2. In a sewing-machine, the combination with a rotary loop-taker, of a non-rotary body portion supported in position with a thread-receiving space between it and said loop-taker and also having means for directing one side of a thread-loop engaged by the loop-taker into said thread-receiving space, and a forked loop-holder pivotally attached to said body portion and also having connection with the loop-taker to be movable therewith.

3. In a sewing-machine, the combination with a rotary loop-taker, of a non-rotary body portion supported by said loop-taker in position with a thread-receiving space therebetween and also having means for directing one side of a thread-loop engaged by the loop-taker into said thread-receiving space, and a forked loop-holder attached to said body portion and also having connection with the loop-taker to be movable therewith.

4. In a sewing-machine, the combination with a rotary loop-taker, of a non-rotary body portion removably supported by said loop-taker in position with a thread-receiving space therebetween and also having means for directing one side of a thread-loop engaged by the loop-taker into said thread-receiving space, and a forked loop-holder attached to said body portion and also having connection with the loop-taker to be movable therewith.

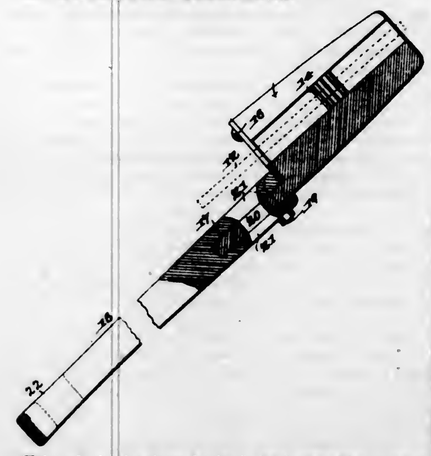
5. In a sewing-machine, the combination of a rotary loop-taker and a non-rotary body portion, the said loop-taker and body portion being provided, one with a groove and the other with a flange extending into said groove, and a forked loop-holder attached to said body portion and also having connection with the loop-taker to be movable therewith.

6. In a sewing-machine, the combination of a rotary loop-taker and a non-rotary body portion, the said loop-taker and body portion being provided, one with a groove and the other with a flange extending into said groove, a forked loop-holder attached to said body portion and also having connection with the loop-taker to be movable therewith, and a movable retainer for removably retaining said body portion in connection with the loop-taker.

7. In a sewing-machine, the combination of a rotary loop-taker having a groove, a non-rotary body portion having a flange extending into the groove of said loop-taker, a forked loop-holder attached to said body portion and also having connection with the loop-taker to be movable therewith, and a movable retainer for engaging with the flange of said body portion to removably retain the latter in connection with the loop-taker.

8. In a sewing-machine, the combination of a rotary loop-taker having a groove, a non-rotary body portion having a flange extending into the groove of said loop-taker, a forked loop-holder attached to said body portion and also having connection with the loop-taker to be movable therewith, a pivoted retainer for engaging with the flange of said body portion to removably retain the latter in connection with the loop-taker, and a latch for holding said retainer in operative retaining position.

809,601. **TROLLEY-WIRE CLAMP.** Edmond L. Baker, Roanoke, Va. Filed Feb. 24, 1906. Serial No. 247,163.



Claim.—1. A wire-clamp having a head comprising a single casting provided with a longitudinal channel which is tapered forwardly and intersects opposite ends of the head, one side of the head being provided with a longitudinal slot intersecting the channel throughout its length and forming an entrance-opening thereinto, a plate secured to the rear end of the head to close the channel and provided with a slot intersecting one edge of the plate and communicating with the entrance-slot of the channel, and a loose clamping-roller working in the channel.

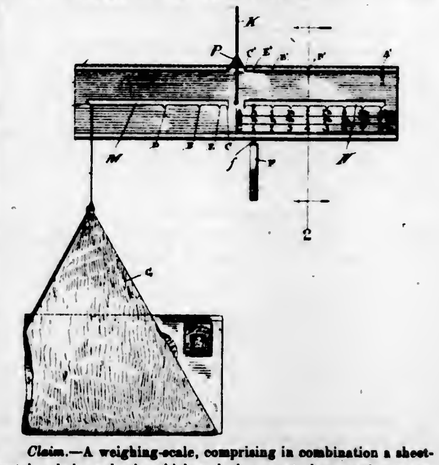
2. A wire-clamp comprising a head and a handle, the head consisting of a single casting having a longitudinal channel intersecting opposite ends of the head and tapered toward the outer end thereof, one side of the head being provided with a longitudinal slot intersecting the ends of the head and one side of the channel throughout its length, the other side of the head being provided with a longitudinal extension having a handle connected thereto and offset at one side of the channel, a plate secured to the rear end of the head and closing the channel and provided with a slot communicating with the channel and the entrance-opening thereof, and a clamping-roller working loosely within the channel.

3. In a clamping device, a rigid head member having a longitudinal channel with walls diverging rearwardly and with one wall provided with a longitudinal concavity and a constricted longitudinal opening, a cylindrical member mounted loosely in said cavity and in opposed relation to the groove and a plate covering the rearward end of the cavity and provided with an opening registering with the groove.

4. In a clamping device, a head member having a rearwardly-projecting lug and with a longitudinal cavity with the walls diverging toward the rear end, a contracted channel communicating with said cavity at one side through one wall of the head member, a stop-plate detachably connected to said head member and extending over the larger end of said cavity and with a recess of less size than said larger end and coinciding with said channel, a cylindrical member operative in said cavity and retained therein by said stop-plate for bearing upon a wire inserted into said cavity through said channel and coinciding recess, a handle member of non-conductive material and provided with a socket bearing over said lug and against said stop-plate, and means for securing said handle member to said lug.

5. As a new article, a clamping device comprising a head member having means for detachable coupling to a conductor-wire and provided with a projecting lug with a transverse aperture through the same, and a handle member of non-conductive material and provided with a socket fitting over said lug and secured thereto and having transverse apertures in alinement with the aperture in said lug.

809,602. **PORTABLE SCALE.** Elias E. Barakat, Washington, D. C. Filed Sept. 13, 1905. Serial No. 278,273.



Claim.—A weighing-scale, comprising in combination a sheet-metal scale-beam having thickened edges, central supporting means therefor, there being a longitudinal slot in each half of the beam, a weight slidably carried in one of said slots, a scale-pan slidably carried in the other slot, both slots being graduated, the weight-slot with equivalent marks and the object-slot with marks set at distances in increasing multiple from the center, and a counterpoise slidably engaging the upper edge of the weight-arm, said edge being graduated to correspond with the graduations of the object-slot.

809,603. **FLUSH.** Andrew J. Barr, Mansfield, Ohio, assignor of one-half to Herman B. Homberger, Mansfield, Ohio. Filed Feb. 25, 1905. Serial No. 247,291.

Claim.—1. In a flush-valve mechanism, in combination with a reservoir of a standard having an aperture formed in the center thereof in alinement with the reservoir and secured to the upper portion of said reservoir, a tapered orifice formed in said standard at right angles therewith, a rotatable tapered pin fitted to said orifice having a portion made eccentric and adapted to aline with the reservoir permitting the water from the inlet-pipe to flow into the reservoir, a rod hooked to the eccentric portion of the pin with the opposite end hooked to a valve located in the lower portion of the reservoir.

2. A flushing device composed of a reservoir, with both ends interiorly screw-threaded, a support having one end exteriorly threaded and adapted to engage with the screw-threaded top of the reservoir, an inlet-aperture formed in said standard communicating with

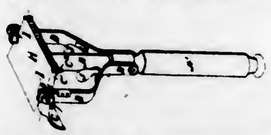
the reservoir, a tapered orifice formed in the support transverse to said aperture, a tapered pin fitted thereto, an eccentric formed on said pin in direct alinement with the inlet-aperture of the support, a rod pivotally journaled to said eccentric on one end, an outlet-bushing fitted to the lower portion of the reservoir having a valve-seat formed thereon, a valve fitted to said bushing and connected to the opposite end of said rod, an operating-lever secured to the projecting end of the tapered pin.

3. In a flushing device, a reservoir having an inlet and outlet in alinement with each other, a support having enlarged projecting portions attached to the upper portion of the reservoir, an inlet-aperture formed therein, a tapered orifice formed transverse to and intersecting said inlet-aperture, a tapered pin fitted to said orifice having an eccentric portion, a bushing fitted to the lower portion of the reservoir with a valve-seat formed thereon, a rod pivotally connected to said valve and tapered pin, a lever secured to said pin providing a means of opening the valve when movement is imparted to the pin.

4. A flushing-valve mechanism comprising a reservoir and support, a tapered pin having an eccentric portion formed thereon fitted to the support, a bushing secured to the lower portion of the reservoir, a valve, a rod adapted to pivotally connect said valve and tapered pin, an operating-lever attached to said pin substantially as described and for the purpose set forth.

5. In a flush for closets, comprising a reservoir with a support attached to the upper portion, said support having an aperture communicating with the reservoir, a tapered orifice formed in said support intersecting with said aperture, a tapered pin having an eccentric portion fitted to said orifice, a bushing adapted to form a valve-seat secured to the lower portion of the reservoir, a valve adapted to contact with said valve-seat, a rod pivotally connecting said valve and tapered pin, a lever secured to the projecting end of the pin as described and set forth.

809,604. **SAFETY-RAZOR.** SAMUEL G. BROSIUS, Washington, D. C. Filed Feb. 21, 1905. Serial No. 246,694.



Claim.—1. In a safety-razor, the combination with a handle, of a shield member mounted thereon, a razor-blade, a supporting member for the razor-blade mounted on said handle, and means interposed between the handle and one of said members and movable longitudinally of the handle, whereby the said razor blade and shield may be moved clear of each other, substantially as described.

2. In a safety-razor, a handle having a shield mounted thereon, a razor-blade, a member for holding the razor-blade, and means interposed between said member and the handle and movable longitudinally thereof to lift the blade free of the shield, substantially as described.

3. In a safety-razor, a handle having a shield mounted thereon, a razor-blade, a member fulcrumed on the handle for holding the razor-blade, and means interposed between the said member and handle and movable longitudinally thereof to lift the blade and permit it to swing free of the shield, substantially as described.

4. In a safety-razor, a handle having a shield mounted thereon, a razor-blade, a member for supporting the razor-blade having a yielding connection with the handle and movable longitudinally thereof and normally holding the razor-blade in operative relation with the shield, whereby the razor-blade may be lifted free of the shield, substantially as described.

5. In a safety-razor, a handle having a shield mounted thereon, a razor-blade, a member for supporting the razor-blade having a yielding pivotal connection with the handle and normally retaining the blade in operative relation with the shield and movable longitudinally of the handle to lift the blade and permit it to swing free of the shield, substantially as described.

6. In a safety-razor, a handle having a shield mounted thereon, a razor-blade, a member for holding the blade normally in operative relation with the shield and movable longitudinally of the handle and having a pivotal connection therewith, whereby the blade is adapted to be lifted and swung free of the razor-shield, substantially as described.

7. In a safety-razor, a handle having a shield mounted thereon, a razor-blade, a spring-retained member for holding the blade normally in operative relation with the shield and movable longitudinally of the handle, and having a pivotal connection therewith, whereby the blade is adapted to be lifted and swung free of the razor-shield, substantially as described.

8. In a safety-razor, a handle having a shield mounted thereon, a member movable longitudinally of the handle for supporting the razor-blade, and adapted to be moved so as to lift the said blade free of the shield, a double-edged razor-blade pivotally mounted in said movable member, whereby it may be rotated in its bearings to reverse the cutting edge, substantially as described.

9. In a safety-razor, a razor-blade having notches in its ends, a handle having a razor-shield mounted thereon, and a two-armed fork mounted on said handle provided with grooved clips rotatably mounted thereon and adapted to fit in the notches of the said razor-blade to hold it in position, substantially as described.

10. In a safety-razor, a razor-blade having curved ends, a handle provided with a razor-shield, and a fork having two arms pivotally mounted on said handle normally holding said razor-blade and adapted to be pressed apart to release the said blade, substantially as described.

11. In a safety-razor, a razor-blade, a handle provided with a razor-shield, a two-armed fork movable longitudinally of the handle normally retaining said blade in position, each of the arms thereof having a clip for engaging the razor-blade and adapted to be pressed apart to release the said blade, substantially as described.

12. In a safety-razor, a razor-blade, a handle, a razor-shield having razor-stops thereon, a fork mounted on the said handle and provided with clips to hold the razor-blade in place on said shield and against said stops, and a spring bearing against the fork, substantially as described.

13. In a safety-razor, a razor-blade, a handle, a razor-shield having a razor-guard, a fork movably mounted on the said handle and provided with clips to hold the said razor-blade in position, razor-stops on the said guard, and a spring on the handle for automatically setting the razor-blade against said stops, substantially as described.

14. In a safety-razor, a razor-blade, a handle, a razor-shield mounted thereon and provided with razor-blade rests, in combination with a fork movably mounted on the said handle, and a spring on the handle connected with the fork for normally holding the razor-blade in position on said rests, substantially as described.

15. In a safety-razor, a razor-blade, a handle provided with a razor-shield, in combination with a two-armed fork provided with clips rotatably mounted in the arms thereof and having knobs for turning the said blade, substantially as described.

16. In a safety-razor, a razor-blade, a razor-shield mounted on the handle, a supporting member having clips to hold the said razor-blade in position, cornered bearings on the said member on which the clips are rotatably mounted, in combination with spring-clamps adapted to hold the said clips and the razor-blade in their several positions, substantially as described.

17. In a safety-razor, a handle, a razor-shield and a fork movably mounted on said handle, a razor-blade supported in the fork, and a spring connection between the fork and handle, substantially as described.

18. In a safety-razor, a razor-blade, a handle having slots in its side, a trunnion-bar moving therein, a spring in the said handle to hold the said trunnion-bar in place, in combination with a razor-shield secured to the said handle, and a fork mounted on the said trunnion-bar and adapted to hold the said razor-blade in position, substantially as described.

19. In a safety-razor, a razor-blade, a handle and a trunnion-bar moving therein and having one side flattened, a spring having a spring-block to hold the trunnion-bar in place, in combination with a razor-shield secured to the said handle, and a fork mounted on the said trunnion-bar and adapted to hold the said razor-blade in its several positions, substantially as described.

20. In a safety-razor, a razor-blade, a handle provided with a trunnion-bar moving therein, a spring having a spring-block adapted to hold the trunnion-bar in place, in combination with a razor-shield secured to the said handle, and a fork mounted on the said trunnion-bar to hold the said razor-blade in its several positions, substantially as described.

21. In a safety-razor, a razor-blade, a handle provided with a resilient fork movably mounted thereon, a spring connection between the handle and fork, the arms of said fork normally holding the razor-blade in position, substantially as described.

22. In a safety-razor, a razor-blade, a razor-shield, a handle provided with a fork movably mounted thereon, and a spring connecting the fork and handle, substantially as described.

23. In a safety-razor, a handle having a razor-shield, a razor-blade having two cutting edges, in combination with a two-armed fork movably secured to said handle, each arm of said fork having a clip rotatably mounted therein, the said blade being held by the clips and free to turn therewith to present either of the said edges, substantially as described.

24. In a safety-razor, a handle having a razor-shield secured thereto, trunnions and a fork longitudinally movable on the handle, in combination with a razor-blade held in position on the said razor-shield, through the agency of the said fork and adapted to swing clear of the said razor-shield, substantially as described.

25. In a safety-razor, a handle having a razor-shield secured thereto, trunnions and a two-armed fork longitudinally movable on the handle, each arm of the said fork having clips, in combination with a razor-blade held in position on the said razor-shield by the said clips and being adapted to swing clear of the said razor-shield, through the agency of the said fork, substantially as described.

26. In a safety-razor, a razor-blade, a handle having a razor-shield secured thereto and provided with a two-armed fork longitudinally movable on the said handle, the said arms having clips adapted to turn therein and to hold the said razor-blade in its several positions, in combination with a controlling-spring, substantially as described.

27. In a safety-razor, a razor-blade, a handle provided with a razor-shield having beveled notches on its sides, a two-armed fork movable longitudinally on the said handle and having clips adapted to fit into the said bevel-notches and to hold the said razor-blade in position, substantially as described.

28. In a safety-razor, a razor-blade, a handle provided with a razor-shield, a two-armed fork mounted upon the said handle, each arm provided with a clip having a rounded edge groove, the said clips being adapted to hold the said blade in position, substantially as described.

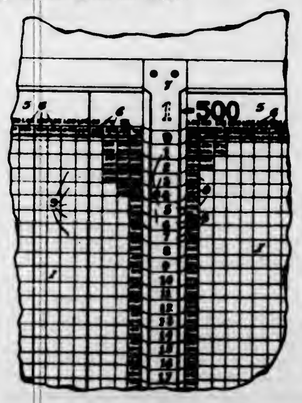
29. In a safety-razor, a razor-blade, a handle having a razor-shield secured thereto, razor-stops on the front of the said shield, trunnions and fork-arms mounted thereon and adapted to support the said fork, in combination with means for automatically adjusting the said blade against the said razor-stops, substantially as described.

30. In a safety-razor, a handle having an upper and a lower part detachably secured together, a razor-shield mounted on the upper part of the said handle, trunnions and fork-arms movably mounted thereon, in combination with a razor-blade held in position on the said shield through the agency of the said fork, substantially as described.

31. In a safety-razor, spring-fork arms provided with a razor-blade mounted thereon, and a razor-shield, in combination with push-bars between the arms of the fork to spread the arms of the said fork in releasing the said blade from the said arms, substantially as described.

32. In a safety-razor, a razor-shield, a handle provided with spring-fork arms pivotally secured thereto and having a razor-blade mounted thereon, in combination with back stops adapted to prevent the razor-blade from being swung back, substantially as described.

809,605. **COMPUTING DEVICE.** GEORGE M. BROWN, Otto, N. Y. Filed July 27, 1905. Serial No. 271,801.



Claim.—1. A computing device of the character described which is divided into a number of main divisions designated by the hundreds, each of said main divisions being divided into a number of columns for the different prices, and each of the columns being subdivided into one hundred spaces, each of which contains two figures, one of them giving the value of the quantity of goods designated by the number of hundreds marked upon the main division plus the quantity designated by the position of the space in the column, said value being according to the price value of the column, while the opposite figure gives the value of that quantity of goods plus one thousand units of the goods.

2. The combination of a computing device of the character described which is divided into a number of main divisions designated by the hundreds, each of said main divisions being divided into a number of columns for the different prices, and each of the columns being subdivided into one hundred spaces, each of which contains two figures, one of them giving the value of the quantity of goods designated by the number of hundreds marked upon the main division plus the quantity designated by the position of the space in the column, said value being according to the price value of the column, while the opposite figure gives the value of that quantity of goods plus one thousand units of the goods, and a rod located over the table and parallel with the price-columns, said rod being divided into one hundred transverse divisions corresponding to the one hundred spaces in the price-columns and numbered from 0 to 99, said numerals designating the number of units to be added to the number of hundreds marked upon the main division in determining the quantity of goods, the device being made so that the rod can be brought to any desired portion of the table.

3. The combination of a cylinder having a table of the character described on the surface thereof, said table being divided into a number of main divisions running longitudinally of the cylinder, each of the main divisions being divided into a number of columns for the different prices, and each of the columns being subdivided into one hundred spaces, each of which contains two figures, one of them giving the value of the quantity of goods designated by the number of hundreds marked upon the main division plus the quantity designated by the position of the space in the column, said value being according to the price value of the column, while the opposite figure gives the value of that quantity of goods plus one thousand units of the goods, and a fixed rod located adjacent the cylinder and parallel with the price-columns, said rod being divided into one hundred transverse divisions corresponding to the one hundred spaces in the price-columns and numbered from 0 to 99, said numerals designating the number of units to be added to the number of hundreds marked upon the main division in determining the quantity of goods, the cylinder being adapted to rotate so as to bring any desired portion of the table around to the rod.

809,606. **GAME APPARATUS.** FREDERICK W. BURNS, Boston, Mass. Filed Aug. 2, 1905. Serial No. 272,286.

Claim.—1. An elongated, rectangular alley having a pocket at one end, and a return-duct leading from the pocket to the opposite end of the alley, a group of pins fixedly suspended above the alley in front of the pocket, a normally depending, pivotally-connected extension on each pin, adapted to be hit and swung upward by a ball traversing the alley, a single instrumentality to automatically lock an extension in either its depending, normal position, or in abnormal position when swung upward, and manually-controlled means to simultaneously restore to depending position such extensions as have been swung upward.

2. An elongated, rectangular alley, a group of swinging pin-like members suspended above the alley in front of the pocket and normally depending toward the alley, a spring connected with each member to retain it either in normal, or in abnormal position, and means to simultaneously restore to normal position all members abnormally positioned.

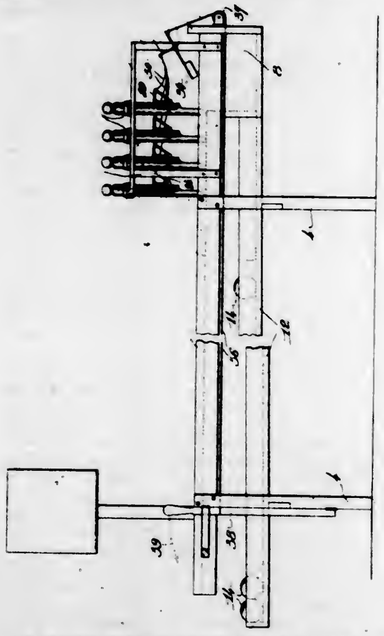
3. An elongated, rectangular alley, a group of pins fixedly suspended above one end thereof and beveled at their lower ends, an extension pivotally connected with each pin and beveled correspondingly, a spring to retain the beveled portions of the pin and extension in contact and thereby maintain the extension alined with the pin, and also to retain the extension elevated when swung rearwardly, a resetting member for each extension, and manually-controlled means to act through the resetting members of all abnormally-positioned extensions and simultaneously reset them.

4. An elongated alley having a pocket at one end and longitudinal side gutters leading thereto, a return-conduit from the pocket

guide and provided with spaced recesses adapted to register with

vided with a notch 6; of a stationary bar 5 engaging the notch, a shuttle-thread hook, an oscillating bar 9 on which the said hook is

to the opposite end of the alley, a group of vertically-adjustable, two-part pins suspended above the alley, in front of the pocket, the lower part or extension of each pin being pivoted to the fixed upper part, a single instrumentality to hold the extensions in alinement with the upper parts, and also at an angle thereto when struck by a ball traversing the alley, and means manually operated from the front end of the alley to simultaneously restore to alined position all extensions which have been previously moved into abnormal position.



5. An elongated alley, an overhead frame at one end, a group of triangularly-arranged pins suspended from the frame, a depending extension pivoted on the lower end of each pin and normally in alinement therewith and in the path of a ball traversing the alley, engagement of the ball with an extension swinging the latter upward, a single instrumentality to automatically retain the extensions in depending or in upturned position, and manually-controlled means to reset the extensions in depending position, in alinement with the pins to which they are pivoted.

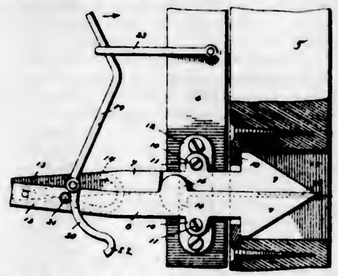
809,607. **TEA-STRAINER HOLDER.** ABRAHAM CHUNDELAH, San Francisco, Cal. Filed Nov. 5, 1904. Serial No. 231,562.

Claim.—1. As an article of manufacture a holder of the character described comprising a single piece of wire bent to form opposed jaws and opposed finger-holds and an intermediate spring-hinge, said jaws adapted to grip the exterior of a vessel, said wire being extended substantially laterally to and provided with means forming a swivel-support for a straining-basket.

2. As an article of manufacture, a holder of the character described comprising a single piece of wire fashioned to form opposed jaws at one portion and opposed finger-holders at another and opposite portion, and a spring portion intermediate of the jaws and finger-holds, said jaws adapted to grip the outside of a vessel and said wire having one terminal extended laterally so that it may extend forward of the spout of the vessel, and said extended terminal having means forming a swivel-support for a straining-basket.

3. As an article of manufacture, a holder of the character described comprising opposed jaws and opposed finger-holds and an intermediate hinge portion, and a rod projecting laterally from the jaw portion and having its outer end provided with means forming a swivel-support for a straining-basket.

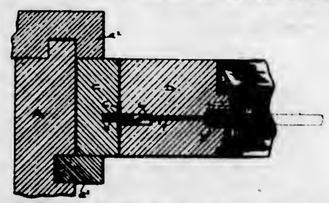
809,608. **GATE-LATCH.** JOHN S. DRENNAN, Cleburne, Tex. Filed May 22, 1905. Serial No. 261,610.



Claim.—1. A gate-latch comprising pivoted arms having hooked front ends, the inner edges of said ends being raised and engaging behind each other; a spring fastened to the rear ends of the arms for holding the hooked ends spread out; and a lever pivoted to one of the arms, and engaging the other arm for spreading said rear ends and drawing the hooked ends together.

2. A gate-latch comprising pivoted arms having hooked front ends which are normally spread out, the inner edges of said ends being raised and engaging behind each other; and emans for drawing the hooks together.

809,609. **WINDOW-SASH.** HARRY W. J. EDBROOKE and FREDERICK LINDQUIST, Chicago, Ill. Filed Mar. 2, 1905. Serial No. 248,010.



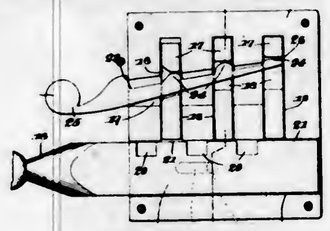
Claim.—1. In combination with a frame and a sash mounted therein, said sash having two-part stiles as described, and the parts of the stiles having registering vertical grooves formed in their adjacent faces, a metal locking-bar arranged in said grooves, and means for operating said bar said means comprising an eccentrically-pivoted and recessed lever connected with said bar and a spring adapted to lock said lever in its adjusted positions.

2. In combination with a frame and a sash mounted therein, said sash having two-part stiles as described, and the parts of the stiles having registering vertical grooves formed in their adjacent faces and metal channel-bars arranged in said grooves, a metal locking-bar arranged in said channel-bars, and means for operating said locking-bar, said means comprising a hollow box secured to the inner face of the sash-stile, a recessed lever eccentrically pivoted in said box and a strap connecting said lever and said locking-bar one end of said strap fitting the recess in said lever.

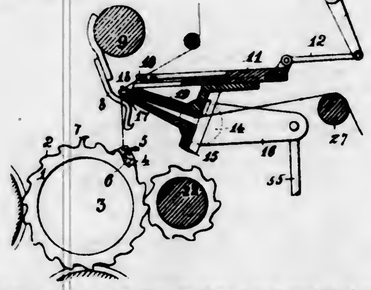
3. In combination with a frame and a sash mounted therein, said sash having two-part stiles as described and the parts of each stile having registering vertical grooves formed therein, channel-bars fixed in said grooves, a metal locking-bar arranged in said channel-bars, and means for operating said locking-bar, said means comprising a box secured to the stile, a slotted recessed and notched lever eccentrically pivoted in said box, a strap connected with said locking-bar and having a pin fitting the slots in the lever, one end of said bar adapted to move in the recessed portion of the lever, and a spring adapted to engage the notches in said lever and hold it in its adjusted positions.

809,610. **DOOR-LOCK.** CHARLES F. FRINGER, Lithia, Va. Filed Sept. 20, 1904. Serial No. 224,895.

Claim.—In a lock, an inclosing casing having a transverse bolt-guide and provided with a plurality of tumbler-guides disposed at right angles thereto, a locking-bolt slidably mounted in the bolt-guide and provided with spaced recesses adapted to register with the tumbler-guides when the bolt is projected, said bolt being provided with an elongated slot and having one end thereof terminating in a handle, a tapering key-guide formed in the casing and intersecting the tumbler-guides, tumblers provided with transverse openings slidably mounted in the tumbler-guides and adapted to engage the recesses in the bolt, one of said tumblers being shorter than the other and having the lower wall of its recess inclined toward the handle of the bolt, a tapering key fitting in the key-guide and having a shoulder at its enlarged end for engagement with the adjacent wall of the casing, said key being provided with a plurality of spaced lateral lugs increasing in size toward said shoulder and having terminal curved portions adapted to engage the transverse openings in the sliding tumblers for actuating the same when the key is tilted upon the forward terminal of the key-guide as a fulcrum, a pin projecting from the casing and adapted to engage the walls of the slot in the sliding bolt for limiting the longitudinal movement of the latter, and a plate detachably secured to the casing and forming a cover for said lock.



809,611. **NET-MAKING MACHINE.** ALEXANDER O. HANNER and GUSTAV HANNER, Christiania, Norway. Filed Sept. 23, 1904. Serial No. 225,639.



Claim.—1. In a net-making machine, a hook capable of engaging a shuttle-thread to form a loop, a needle capable of carrying a bight of the warp-thread through the shuttle-thread loop to bring it in the path of a warp-thread hook, a shuttle, a toothed ring surrounding said shuttle, means to support said ring, a toothed wheel to impart rotary motion to said ring and a warp-thread hook on said ring.

2. In a net-making machine the combination with a shuttle-thread loop-forming hook, a shuttle and a warp-thread hook of a warp-thread needle, means to move the needle longitudinally, guides for the shuttle and the warp-thread in the proximity of the needle, and means to alternately bring these guides close to the knot-forming point and to lift them above the shuttle-thread loop-former.

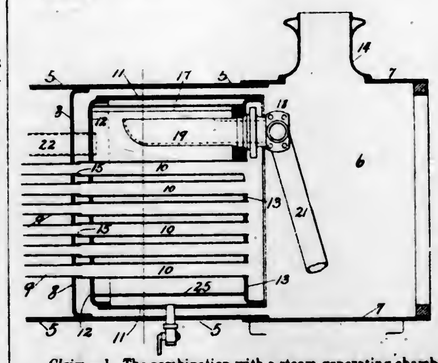
3. In a net-making machine a rocking frame, a wing on the same projecting toward the knot-forming point, a shuttle, a guide-comb for the shuttle-threads on the edge of said wing, a support on said rocking frame, means to impart a reciprocating motion to said support in a direction parallel to the axis of the rocking frame, a wing on said support extending toward the edge of the wing on the rocking frame and a guide-comb for the warp-threads on the edge of said wing, a slide on the rocking frame, means to move the same in a direction at right angles to the motion of the support and warp-thread needles mounted on said slide.

4. In a net-making machine, the combination with a rotatable toothed shuttle-carrier having a hook thereon, a toothed wheel engaging the shuttle-carrier and a shuttle mounted in the carrier having a perforated plate 4 projecting at one side of the carrier and provided with a notch 6; of a stationary bar 5 engaging the notch, a shuttle-thread hook, an oscillating bar 9 on which the said hook is mounted, a warp-thread needle, a slide on which the needle is mounted, mechanism to move said slide to give the needle longitudinal movement, a support for said slide, means to move the support laterally, a frame 15 in which the support is mounted, means to rock the frame, a comb on the support and a comb on the frame having upwardly-bent teeth, said combs opposite one another and between which the finished net passes, means to laterally move the bar 9, substantially as described.

5. In a net-making machine, the combination with a toothed shuttle-carrier, a hook thereon, means to rotate the carrier and a shuttle-thread loop-forming hook; of a warp-thread needle having a bend back of its eye, means to rock the needle into position to be projected through the shuttle-thread hook, means to project the needle through the loop to carry the warp-thread into the path of the shuttle-carrier hook, whereby the point of said hook will pass the needle at its bend and loop the warp-thread around the shuttle, substantially as described.

6. In a net-making machine, a rocking frame having a comb at its front, a support mounted to move laterally in the frame and having a comb at its front, said support having a free space for the passage of the finished net between its under side and the top of the rocking frame, a slide mounted to move in the support transversely and warp-thread needles mounted on the slide, substantially as described.

809,612. **MEANS FOR SUPERHEATING STEAM.** FRANK A. HAUGHTON, Schenectady, N. Y. Filed Mar. 20, 1905. Serial No. 250,975.



Claim.—1. The combination with a steam-generating chamber, of a superheater, a baffle-plate located in the superheating-chamber to deflect the steam entering the chamber and separate the water therefrom, and a plate located in the lower portion of the superheating-chamber under which the separated water passes.

2. The combination with a steam-generating chamber, of a superheating-chamber, a pair of baffle-plates located in the superheating-chamber to deflect the steam entering the chamber and separate the water therefrom, and a plate located in the lower portion of the superheating-chamber under which the separated water passes.

3. The combination with a steam-generating chamber, of a superheating-chamber, a baffle-plate located in the superheating-chamber, a pipe leading from the generating-chamber to the portion of the superheating-chamber on one side of the baffle-plate, means to convey the steam from the superheating-chamber located on the other side of the baffle-plate, said baffle-plate being arranged to suddenly change the direction of flow of the steam thereby separating moisture or water from the steam and a plate located in the lower portion of the chamber under which the separated water passes.

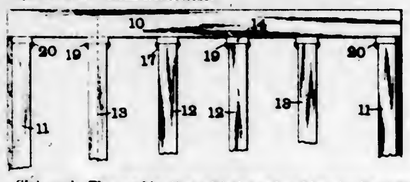
4. The combination with a steam-generating chamber, of a superheating-chamber, a pair of baffle-plates located in the chamber, pipes leading from the generating-chamber to the portion of the superheating-chamber between the plates and the shell of the chamber, means arranged between the plates to convey the steam from the superheater, said plates being arranged to suddenly change the direction of flow of the steam, thereby separating moisture or water from the steam, and a plate located in the lower portion of the chamber under which the separated water passes.

5. The combination with a tubular boiler having an extended

shell, of a superheater consisting of a closed chamber provided with a plurality of fire-tubes and a plurality of baffle-plates, said plates extending longitudinally of the superheater-chamber, means for introducing steam from the boiler to the superheater into the space outside the plates, means for withdrawing the steam from the superheater from the space between the plates, said chamber being separated from the boiler, but contained within the extended shell and fire-tubes in the chamber registering with the tubes of the boiler.

6. The combination with a steam-generating chamber, of a superheater and means located in the superheating-chamber to deflect the steam entering the chamber and separate the water therefrom, and a plate located in the lower portion of the superheating-chamber under which the separated water passes.

809,613. **RAILWAY-CAR.** LOUIS A. HOSER, St. Louis, Mo. Filed Apr. 28, 1905. Serial No. 257,899.



Claim.—1. The combination with the end and longitudinal sills of a car, of a timber-pocket adapted to receive the end of a longitudinal sill and having its lower end permanently open, and means for securing said timber-pocket to said end sill.

2. The combination with the end and longitudinal sills of a car, of a timber-pocket adapted to receive the end of a longitudinal sill and having its lower end permanently open, said longitudinal sill being provided on its upper face with a recess to receive the flange of said pocket.

3. In a railway-car, the combination with end and longitudinal sills of substantially the same depth, of a timber-pocket adapted to receive the end of a longitudinal sill and having its lower end permanently open, and means for securing said timber-pocket to said end sill.

4. The combination with the end and longitudinal sills of a car, of a timber-pocket adapted to receive the end of a longitudinal sill and having its lower end permanently open, means for securing said timber-pocket to the end sill, and means for securing said timber-pocket to the longitudinal sill.

5. The combination with the end and longitudinal sills of a car, of a timber-pocket adapted to receive one end of a longitudinal sill and having its lower end permanently open, a hollow boss provided with a screw-hole for securing said timber-pocket to the end sill, and a lug for securing said timber-pocket to the longitudinal sill.

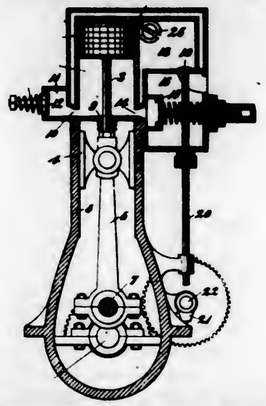
6. The combination with the end and longitudinal sills of a car, of a timber-pocket adapted to receive the end of a longitudinal sill and having one end permanently open, a hollow boss provided with a screw-hole for securing said timber-pocket to the end sill, a pair of lugs carried by said timber-pocket, and a bolt passing through said lugs and the longitudinal sill in said pocket

809,614. **INTERNAL-COMBUSTION ENGINE.** HENRY C. HOLLOWAY, Gilroy, Cal., assignor of one-half to William De Hart, Watsonville, Cal. Filed Feb. 6, 1905. Serial No. 244,486.

Claim.—1. An internal-combustion engine comprising a cylinder closed at both ends, a piston, a piston-rod extending through the stuffing-box in one head, connecting with the cross-head and crank-shaft, inlet and outlet passages contiguous to the lower cylinder-head, automatically-operating valves by which gas is admitted to the cylinder and transmitted therefrom, said valves operated by and during the movement of the single power-piston, a receiver for the compressed gas, an independent combustion-chamber intermediate between said receiver and the cylinder, and a valve controlling the transmission of gas from the receiver to the combustion-chamber.

2. An internal-combustion engine, comprising a cylinder having passages at opposite sides, a piston reciprocating in said cylinder, automatically-controlled inlet and outlet valves through which the impelling medium is transmitted by the movement of the piston, a receiver and a combustion-chamber above the same with a valve between the two and operating in a plane parallel with the piston, and a valve-controlled opening between the combustion-chamber and the working end of the cylinder.

3. In an internal-combustion engine, a cylinder, piston-passages at opposite sides of the inner end of the cylinder said passages being essentially in line, automatically-operating valves through which the impelling medium is first drawn into the cylinder and then compressed and forced out, a receiving-chamber at one side of cylinder and into which the compressed gas passes, a combustion-chamber at one side of the cylinder and in line with the receiver and connecting with the receiver, and a mechanically-operated valve movable in a plane parallel with the piston and through which the compressed gas is admitted to the combustion-chamber, a passage between the combustion-chamber and the working end of the cylinder, and a manually-operated valve controlling said passage.



4. In an internal-combustion engine, a cylinder with reciprocating piston, inlet and outlet valves communicating with opposite sides of the lower end of the cylindar, a receiver on the outside of the cylinder and into which the impelling medium is compressed by the reciprocations of the engine-piston and the opening of said valves, a combustion-chamber on the outside of the cylinder in line with the receiver and intermediate between the receiver and the working end of the cylinder, a mechanically-operating valve through which the compressed gas is delivered to the combustion-chamber, a port opening from the combustion-chamber into the working end of the cylinder, a valve controlling the passage through said port and a mechanically-actuated exhaust-valve connecting with the combustion-chamber.

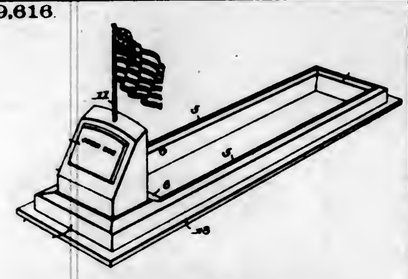
809,615. **PAD-HOLDER.** LOUIS J. HOPKINS, Torrington, Conn. Filed May 1, 1905. Serial No. 259,237.

Claim.—A device for the purpose specified consisting of a bed-plate having its two ends turned upward and serrated, a bowed spring clamping-plate having downwardly-turned serrated ends adapted to pass between the ends of the bed-plate, a pad extending across the under face of the bed-plate and over the serrated ends thereof and beneath the edges of the clamping-plate, and means for connecting the clamping-plate with the bed-plate whereby the pad is held in position, substantially as described.

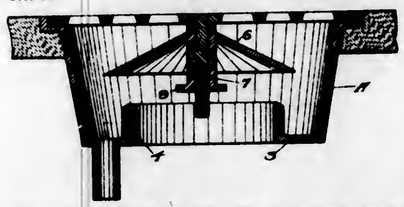
809,616. **HEADSTONE AND GRAVE-MARKER.** AARON H. HOWARD, Salina, Mich. Filed Feb. 23, 1905. Serial No. 247,970.

Claim.—A device of the class described comprising a substantially rectangular curbing adapted to be placed over a grave and provided at one end with an integral transverse reinforcement, a substantially U-shaped bar embedded in the walls of the curbing and having its terminal portions inclined toward the center of the transverse reinforcement, and a tombstone secured to said reinforcement and having a socket formed in the top thereof for the reception of a flagstaff, there being an opening in the rear wall of the tombstone communicating with said socket.

809,616.

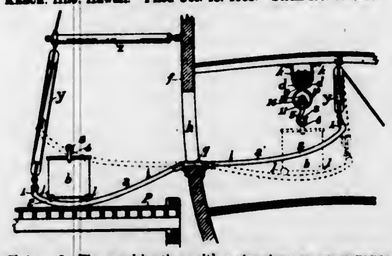


809,617. **VENTILATOR FOR BASEMENTS AND THE LIKE.** PETER H. JACKSON, San Francisco, Cal. Filed June 5, 1905. Serial No. 263,781.



Claim.—In a ventilator, the combination with a casting having a perforated cover, a central air-passage and a gutter or trough with a discharge-passage, of a fixed bolt depending from the cover and extending approximately into said air-passage, a cone adapted as a cover for the air-passage said cone capable of rotation relative to the fixed bolt whereby it breaks up and pulverizes the caked mud which will accumulate and clog the ventilator, said cone having a long bearing on the bolt and said bolt and bearing having a threaded engagement one with the other, and said bearing provided with means by which the cone may be rotated relative to the bolt.

809,618. **LOADING AND UNLOADING DEVICE.** ALVIN W. KEECH, Hilo, Hawaii. Filed Oct. 15, 1903. Serial No. 177,806.



Claim.—1. The combination with a structure or conveyance to be loaded or unloaded, of an arm hinged exteriorly of the structure, means for raising and lowering the arm, a second arm pivotally secured within the structure and forming a continuation of the external arm and a carrier adapted to be supported by the arms.

2. A device of the kind described comprising a carrier designed to enter or come out of a structure or conveyance, through a suitable port therein, and a hinged arm adapted to transfer said carrier to or from the structure or conveyance and momentarily retain it in proximity to said port, substantially as described.

3. A loading and unloading device comprising a track within the structure or conveyance to be loaded or unloaded, an arm hinged to said track, and a carrier adapted to be transferred by said arm to or from the track and structure or conveyance, substantially as described.

4. A device of the kind described comprising a hinged arm, a carrier adapted to be transferred thereby, means for raising and lowering the arm, and an adjustable stop for limiting the downward movement of the arm relatively to the carrier, substantially as described.

5. A device of the kind described comprising one or more arms or tracks, and a carrier adapted to travel along the same, including a truck, a container with a bail having pendants, a hook grasping said bail between its said pendants, and an intermediate hanger permitting a rotary and an oscillatory movement of said hook with relation to said truck and adapted to maintain them rigidly connected after adjustment, substantially as described.

6. A device of the kind described comprising an arm having parallel members, arched braces interconnecting said members, a truck in hinge connection with said arm, and a suspended wheeled carrier adapted to ride on the members of the arms and the connected track, and means for oscillating the arm on its hinge connection, substantially as described.

7. A loading and unloading device comprising a pivotally-supported track-arm, a stop located at the outer free end of the track-arm, the track-arm being substantially U-shaped at a point near its outer end, means for raising and lowering the track-arm and a carrier supported by and traveling on the arm, the contact of the carrier and stop being cushioned owing to the U-shaped portion of the arm.

8. A loading and unloading device comprising a pivotally-supported track-arm, means for raising and lowering the track-arm and a carrier supported by and traveling on the arm, the carrier provided with a bail, a boss secured to the bail, corresponding enlargements on the boss and spaced apart from each other and a hook having a contour conforming to the contours of the enlargements, the hook received between the enlargements.

9. A loading and unloading device comprising a pivotally-supported track, a carrier supported and traveling upon the arm, means for raising and lowering the arm, a guide-member loosely engaging the arm and a stop carried by the guide member and impinged by the arm for limiting the movement of the arm in one direction.

10. A loading and unloading device comprising a suitably-supported movable track-arm, consisting of a single piece of material bent at its outer end, to form parallel rails, braces connecting the rails, means for raising and lowering one end of the arm and a carrier traveling on the arm.

11. A loading and unloading device comprising a track-arm pivotally supported at one end, a truck adapted to travel on the arm, the truck comprising wheels, a slotted hanger connected to the wheels, a suspending device secured to the hanger and projecting through the slot, a carrier supported upon the truck and means for raising and lowering the arm.

12. A loading and unloading device comprising a suitable track, a truck traveling thereon, the truck consisting of wheels, a circular hanger connected to the wheels, a segmental block seated therein, a suspending device passing loosely through the hanger and block and an adjusting member to which the suspending device is secured within the hanger.

13. A loading and unloading device comprising a track-arm, a truck traveling thereon, the truck consisting of wheels a circular hanger connected to the wheels, a segmental block seated in the hanger, a corrugated block resting upon the segmental block, a suspending device passing loosely through the hanger and blocks, and a corrugated adjusting member rigidly secured to the suspending device and engaging the corrugated block.

14. The combination with a structure, of a track pivotally supported externally of the structure, a track pivotally supported interiorly of the structure and forming a continuation of the external track, means for adjusting the interior track at a variety of different elevations and a carrier adapted to travel the tracks.

15. The combination with a structure, of a track pivotally supported exteriorly thereof, a second track supported interiorly of the structure and forming a continuation thereof, an elevated railway secured adjacent one of the tracks, the track movable toward and from the railway, a carrier adapted to be received on the tracks and means on the railway for engaging the carrier to support it independently of the track.

16. The combination with a structure, of a track secured exteriorly of the structure, a second track secured interiorly of the structure, a rail-section stationarily secured to the structure to connect the track-sections and means for adjusting at least one of the tracks at various elevations.

17. The combination with a structure having an opening therein, of a rail-section rigidly secured to one wall of the opening, a track-section pivotally secured to one end of the rail-section and extending exteriorly of the structure, a second track-section pivotally secured to the opposite end of the rail-section and extending interiorly of the structure, a carrier supported by the tracks and means for adjusting at least one of the tracks at various elevations.

18. The combination in a loading and unloading device, of a suitably-supported track, a carrier adapted to be supported by the track, a railway supported upon a different plane from that occupied by the track, means on the railway adapted to engage and support the carrier independently of and previously or subsequently to the track, and means for moving the one relative to the other.

809,619. **BRACELET.** PHILIP H. LESTER, Attleboro Falls, Mass., assignor to T. I. Smith Co., North Attleboro, Mass. Filed June 3, 1905. Serial No. 263,572.

Claim.—1. A two-part tubular bracelet having a spring-actuated concealed hinge consisting of a member having a body portion with a forked end, a member having a body portion with a tongue adapted to enter the forked end of the adjacent member in which it is pivotally secured by a pin, a tube, a coiled spring in the tube one end of which is secured to the member having the tongue and the other end secured to a bar crossing the outer end of the tube, a catch stamped substantially U-shaped from sheet metal the arms of which are rounded on the ends, one arm having a notch and a push-teat adapted to extend through a slot in the bracelet, and means for securing the hinge and catch, whereby the bracelet is opened against the tension of the coiled spring without forming a gap or opening in the hinge-joint of the bracelet, and closed automatically by the tension of the coiled spring, as described.

2. In a bracelet, the combination with the half *a* having the end a' and the half *b* having the end b' of a bracelet, of a spring-actuated concealed hinge *c* consisting of a member c' having the body portion c^3 with the forked end c^3, a member c^4 having the body portion c^5, the tongue c^6 adapted to enter the forked end c^3 in which it is pivotally secured by the pin c^7 forming the pintle of the hinge, and the slot c^8 extending into the body portion c^5, a tube c^9, a coiled spring c^{10} in the tube, one end of the spring being secured to the member c^4 in the slot c^8 by the pin c^{11} and the other end to the bar c^{12} extending across the outer end of the tube c^9, and means for securing the hinge in the bracelet, as described.

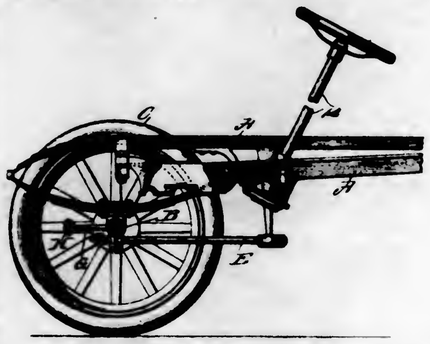
3. In a bracelet, the combination with the half *a* having the end a', the end a^2 in which is the slot a^3, and the half *b* having the end b' and the end b^2 in which is the inwardly-extending lip b^3, of a spring-actuated concealed hinge *c* consisting of a member c' having the body portion c^3 with the forked end c^3, a member c^4 having the body portion c^5, and the tongue c^6 adapted to enter the forked end c^3 in which it is pivotally secured by the pin c^7 forming the pintle of the hinge, and the slot c^8 extending into the body portion c^5, a tube c^9, a coiled spring c^{10} in the tube, one end of the spring being secured to the member c^4 in the slot c^8 by the pin c^{11} and the other end to the bar c^{12} extending across the outer end of the tube c^9, and a U-shaped catch *d* having the arm d' with the rounded end d^2 and the arm d^3 with the rounded end d^4, the notch d^5 and the outwardly-extending push-teat d^6, means for securing the hinge *c* in the ends a' and b' of the bracelet, and means for securing the catch *d* in the end a^2 of the bracelet, as described.

809,620. **STEERING MECHANISM FOR MOTOR-VEHICLES.** THEODORE P. HEUSNER, St. Louis, Mo., assignor to St. Louis Car Company, St. Louis, Mo., a Corporation. Filed Aug. 7, 1905. Serial No. 273,153.

Claim.—1. In a steering mechanism, the combination of a connecting member leading to a steering-wheel, a rocking member having a lever-arm fitted to said connecting member, means for supporting said rocking member, a staff, and a cam fitted to said staff and having its working face disposed in a plane oblique to the axis of said staff and opposed to said rocking member to impart movement thereto, substantially as set forth.

2. In a steering mechanism, the combination of a connecting member leading to a steering-wheel, a rocking member having a lever-arm fitted to said connecting member and having a pair of diverging arms, means for supporting said rocking member, a staff, and a cam fitted to said staff; said cam having a working face disposed obliquely relative to the axis of said staff and opposing the diverging arms of said rocking member, substantially as set forth.

3. In a steering mechanism, the combination of a connecting member leading to a steering-wheel, a rocking member having a lever-arm fitted to said connecting member and diverging arms, bearing-balls seated in said diverging arms, a staff, and a cam fitted to said staff; said cam having a working face disposed obliquely to the axis of said staff and bearing against said bearing-balls to impart movement to said rocking member by pressure against its diverging arms, substantially as set forth.



4. In a steering mechanism, the combination of a connecting member leading to a steering-wheel, a rocking member having a lever-arm fitted to said connecting member and having diverging arms, a casing in which said rocking member is supported, a staff journaled in said casing, and a cam fixed to said staff and having a working face oblique to the axis of said staff and opposing the diverging arms of said rocking member, substantially as set forth.

5. In a steering mechanism, the combination of a connecting member leading to a steering-wheel, a rocking member having a lever-arm fitted to said connecting member and having diverging arms, a casing in which said rocking member is supported, a staff journaled in said casing, and a cam fixed to said staff and having a working face oblique to the axis of said staff and opposing the diverging arms of said rocking member; said cam having a sleeve surrounding said staff and positioned between it and a portion of said casing and being provided with a stop arranged to engage said casing portion, substantially as set forth.

6. In a steering mechanism, the combination with a steering-wheel-connecting member, of a rocking member united to said connecting member, a cam-disk for rocking said rocking member, means for adjusting said cam-disk with respect to said rocking member, substantially as set forth.

7. In a steering mechanism, the combination of a steering-wheel-connecting member, an armed rocking member united to said connecting member, a cam-disk opposing the arms of said rocking member and provided with a sleeve, a casing member in which the sleeve of said cam member is fitted, and means for operating against said sleeve for adjusting said cam member relative to the arms of said rocking member, substantially as set forth.

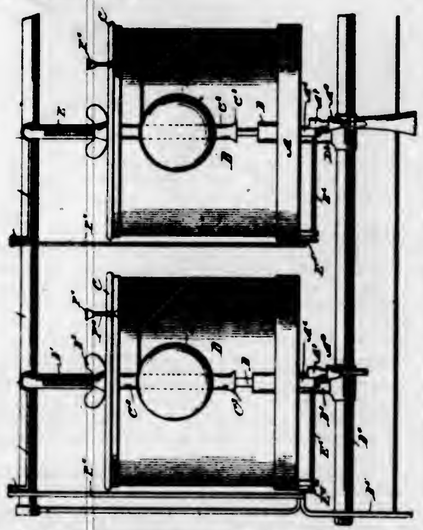
8. In a steering mechanism, the combination of a steering-wheel-connecting member, an armed rocking member united to said connecting member, a cam-disk opposing the arms of said rocking member and provided with a sleeve, a casing member in which the sleeve of said cam member is fitted, and a bearing-cap fitted to said casing member and arranged to impart movement to said cam-disk through the medium of its sleeve, substantially as set forth.

9. In a steering mechanism, the combination of a steering-wheel-connecting member, an armed rocking member united to said connecting member, a cam-disk opposing the arms of said rocking member and provided with a sleeve, a casing member in which the sleeve of said cam-disk is fitted, a bearing-cap fitted to said casing member and arranged to impart movement to said cam-disk through the medium of its sleeve, and a jam-nut arranged to hold said bearing-cap, substantially as set forth.

10. In a steering mechanism, the combination of a steering-wheel-connecting member, a rocking member for actuating said connecting member, and a cam-disk for operating said rocking member having a rim at its edge and provided with an oil-duct located adjacent to said rim, substantially as set forth.

809,621. **BOTTLING-MACHINE.** ERNEST L. HELLER, Louisville, Ky. Filed Apr. 17, 1905. Serial No. 255,676.

Claim.—1. In a bottling-machine, a receptacle, a supply-pipe thereto provided with a valve having an operating-arm, a delivery-valve communicating with said receptacle and provided with an oscillating bottle-tube for operating the same, an operating-arm carried by said delivery-valve, and means extending directly between the arms upon said supply and delivery valves for operating them simultaneously by the movement of the bottle-tube in the insertion and withdrawal of a bottle.



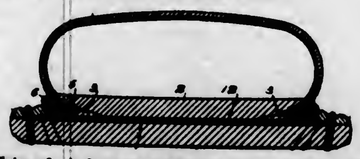
2. In a bottling-machine, a measuring-receptacle, a bottom plate upon which said receptacle rests, a top plate therefor, and means for adjusting said plates at different distances from each other to receive receptacles of different height or capacity.

3. In a bottling-machine, a measuring-receptacle, a bottom plate, a post extending upward therefrom, a top plate provided with a depending sleeve surrounding said post, a float slidably mounted upon said sleeve, and a valve carried by said float to close a vent-opening in said top plate.

4. In a bottling-machine, a measuring-receptacle, a bottom plate, a post extending upward therefrom, a top plate provided with a depending sleeve surrounding said post, a float slidably mounted upon said sleeve, a valve carried by said float to close a vent-opening in said top plate, a laterally-disposed arm carried by said float to support said valve, and a stop-flange at the lower end of said sleeve.

5. In a bottling-machine, a base-plate provided with a seat therein, a packing disposed upon said seat, a supply-pipe communicating with the base beyond said seat, a delivery-pipe communicating with the bottom of said base, an open-ended receptacle seated upon said packing, a vertically-disposed post carried by said plate and provided with a threaded upper end adapted to extend above receptacles of different capacities, a top plate disposed at the upper end of said receptacle, and a holding-nut threaded upon said post to engage said top plate.

809,622. **SHOE.** JAMES N. MOULTON, Haverhill, Mass., assignor to The Waterproof Welt & Filler Co., Hartford, Conn., a Corporation of Delaware. Filed Mar. 14, 1905. Serial No. 249,994.



Claim.—1. A shoe comprising an upper, an inner sole having the usual channel in its bottom, a welt, an integral strip of yielding and elastic waterproof material lying between the welt and the upper, these parts being secured together by a row of stitches passing through the yielding and elastic strip and into the channel in the inner sole, whereby the elastic strip closes around the stitches as the shoe is sewed, thus making the structure waterproof, and an outer sole secured to the welt.

2. A shoe comprising an upper, an inner sole having the usual channel in its bottom, a welt, an integral strip of yielding and elastic waterproof material lying between the welt and the upper, these parts being secured together by a row of stitches passing through the yielding and elastic strip and into the channel in the inner sole whereby the elastic strip closes around the stitches as the shoe is sewed, thus making the structure waterproof, an outer sole secured to the welt, and a waterproof sole-filling material between the outer and the inner soles, the edge of the yielding and elastic strip lying closely in contact with the sole-filling material.

3. A shoe comprising an upper, an inner sole having the usual channel in its bottom, a welt, an integral strip of yielding and elastic waterproof material lying between the welt and the upper, these parts being secured together by a row of stitches passing through said strip and into the channel in the inner sole, whereby said strip closes around the stitches as the shoe is sewed, thus making the structure waterproof, an outer sole secured to the welt, and a waterproof sole-filling material between the inner and outer soles, the edges of said material extending underneath the welt.

4. A shoe comprising an upper, an inner sole, a welt, an integral strip of waterproof filling material lying between the welt and the upper, said parts being secured together by a row of stitches, an outer sole secured to the welt, and a filling material having a relatively thick central portion and a relatively thin edge between the soles, the thin edge lying between the welt and the outer sole.

809,623. **WATERPROOF SOLE.** JAMES N. MOULTON, Philadelphia, Pa., assignor to John R. Reynolds, Hartford, Conn. Filed May 18, 1904. Serial No. 208,515.

Claim.—1. A waterproof protector and filler for welted shoes to be interposed between the inner and outer soles thereof, said protector including a body portion comprising a sheet of waterproof material and a filler-section attached thereto, and a relatively thin flexible waterproof edge, the thicker body portion serving as a filler for the cavity between the soles.

2. A waterproof protector and filler for welted shoes to be interposed between the inner and outer soles thereof, said protector comprising a sheet of rubber, a reinforcing-sheet and a filler-section, the filler-section being of a size to be contained within the cavity existing between the inner and outer soles and bounded by the edge of the welt and forming in connection with the rubber and the reinforcing-sheet a body portion, the rubber extending beyond the body portion and forming a thin flexible edge to overlie the seam by which the welt is secured to the upper and inner soles.

3. A waterproof protector and filler for welted shoes to be interposed between the inner and outer soles thereof, comprising a sheet of rubber, a filler-section secured to the sheet of rubber, said section being of a size to be contained within the cavity existing between the inner and outer soles, and a reinforcing-sheet on the side of the rubber sheet opposite to that on which the filler-section is mounted, the filler-section, rubber and reinforcing-sheet forming a body portion and the rubber and reinforcing-sheet extending beyond the body portion and forming a relatively thin flexible edge to overlie the seam by which the welt, upper and inner soles are secured together.

4. A shoe comprising an upper, an inner sole and a welt stitched together, an outer sole, and a waterproof protector or filler interposed between the inner and outer soles, said protector including a body portion comprising a sheet of waterproof material and a filler-section and a relatively thin flexible waterproof edge, the thicker body portion serving as a filler for the cavity between the soles, and the thin flexible waterproof edge serving to overlie the seam by which the welt, upper and inner sole are secured together.

5. A shoe comprising an upper, an inner sole and a welt stitched together, an outer sole, a waterproof protector and filler interposed between the inner and outer soles, said protector comprising a sheet of rubber, a reinforcing-sheet and a filler-section, the filler-section being contained within the cavity existing between the inner and outer soles and bounded by the edge of the welt, and forming in connection with the rubber sheet and the reinforcing-sheet a body portion, the rubber extending beyond the body portion and forming a

18. The combination in a loading and unloading device, of a suitably-supported track, a carrier adapted to be supported by the track, a railway supported upon a different plane from that occupied by the track, means on the railway adapted to engage and support the carrier independently of and previously or subsequently to the track, and means for moving the one relative to the other.

809,619. **BRACELET.** PHILLIP H. LESTER, Attleboro Falls, Mass., assignor to T. I. Smith Co., North Attleboro, Mass. Filed June 3, 1905. Serial No. 263,572.

Claim.—1. A two-part tubular bracelet having a spring-actuated concealed hinge consisting of a member having a body portion with a forked end, a member having a body portion with a tongue adapted to enter the forked end of the adjacent member in which it is pivotally secured by a pin, a tube, a coiled spring in the tube one end of which is secured to the member having the tongue and the other end secured to a bar crossing the outer end of the tube, a catch stamped substantially U-shaped from sheet metal the arms of which are rounded on the ends, one arm having a notch and a push-teat adapted to extend through a slot in the bracelet, and means for securing the hinge and catch, whereby the bracelet is opened against the tension of the coiled spring without forming a gap or opening in the hinge-joint of the bracelet, and closed automatically by the tension of the coiled spring, as described.

2. In a bracelet, the combination with the half *a* having the end *a'* and the half *b* having the end *b'* of a bracelet, of a spring-actuated concealed hinge *c* consisting of a member *c'* having the body portion c^3 with the forked end c^4, a member c^5 having the body portion c^6, the tongue c^7 adapted to enter the forked end c^4 in which it is pivotally secured by the pin c^7 forming the pintle of the hinge, and the slot c^8 extending into the body portion c^6, a tube c^9, a coiled spring c^{10} in the tube, one end of the spring being secured to the member c^5 in the slot c^8 by the pin c^{11} and the other end to the bar c^{12} extending across the outer end of the tube c^9, and means for securing the hinge in the bracelet, as described.

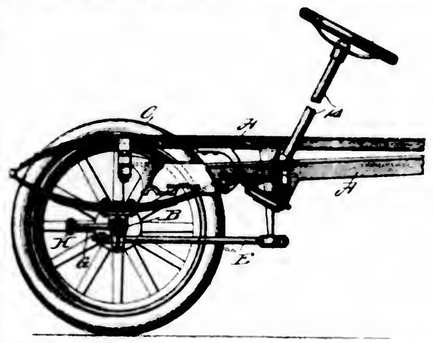
3. In a bracelet, the combination with the half *a* having the end *a'*, the end a^2 in which is the slot a^3, and the half *b* having the end *b'* and the end b^2 in which is the inwardly-extending lip b^3, of a spring-actuated concealed hinge *c* consisting of a member *c'* having the body portion c^3 with the forked end c^4, a member c^5 having the body portion c^6, and the tongue c^7 adapted to enter the forked end c^4 in which it is pivotally secured by the pin c^7 forming the pintle of the hinge, and the slot c^8 extending into the body portion c^6, a tube c^9, a coiled spring c^{10} in the tube, one end of the spring being secured to the member c^5 in the slot c^8 by the pin c^{11} and the other end to the bar c^{12} extending across the outer end of the tube c^9, and a U-shaped catch *d* having the arm *d'* with the rounded end d^2 and the arm d^3 with the rounded end d^4, the notch d^5 and the outwardly-extending push-teat d^6, means for securing the hinge *c* in the ends *a'* and *b'* of the bracelet, and means for securing the catch *d* in the end a^2 of the bracelet, as described.

809,620. **STEERING MECHANISM FOR MOTOR-VEHICLES.** THEODORE P. MEINHARD, St. Louis, Mo., assignor to St. Louis Car Company, St. Louis, Mo., a Corporation. Filed Aug. 7, 1905. Serial No. 273,199.

Claim.—1. In a steering mechanism, the combination of a connecting member leading to a steering-wheel, a rocking member having a lever-arm fitted to said connecting member, means for supporting said rocking member, a staff, and a cam fitted to said staff and having its working face disposed in a plane oblique to the axis of said staff and opposed to said rocking member to impart movement thereto, substantially as set forth.

2. In a steering mechanism, the combination of a connecting member leading to a steering-wheel, a rocking member having a lever-arm fitted to said connecting member and having a pair of diverging arms, means for supporting said rocking member, a staff, and a cam fixed to said staff; said cam having a working face disposed obliquely relative to the axis of said staff and opposing the diverging arms of said rocking member, substantially as set forth.

3. In a steering mechanism, the combination of a connecting member leading to a steering-wheel, a rocking member having a lever-arm fitted to said connecting member and diverging arms, bearing-balls seated in said diverging arms, a staff, and a cam fitted to said staff; said cam having a working face disposed obliquely to the axis of said staff and bearing against said bearing-balls to impart movement to said rocking member by pressure against its diverging arms, substantially as set forth.



4. In a steering mechanism, the combination of a connecting member leading to a steering-wheel, a rocking member having a lever-arm fitted to said connecting member and having diverging arms, a casing in which said rocking member is supported, a staff journaled in said casing, and a cam fixed to said staff and having a working face oblique to the axis of said staff and opposing the diverging arms of said rocking member, substantially as set forth.

5. In a steering mechanism, the combination of a connecting member leading to a steering-wheel, a rocking member having a lever-arm fitted to said connecting member and having diverging arms, a casing in which said rocking member is supported, a staff journaled in said casing, and a cam fixed to said staff and having a working face oblique to the axis of said staff and opposing the diverging arms of said rocking member; said cam having a sleeve surrounding said staff and positioned between it and a portion of said casing and being provided with a stop arranged to engage said casing portion, substantially as set forth.

6. In a steering mechanism, the combination with a steering-wheel-connecting member, of a rocking member united to said connecting member, a cam-disk for rocking said rocking member, means for adjusting said cam-disk with respect to said rocking member, substantially as set forth.

7. In a steering mechanism, the combination of a steering-wheel-connecting member, an armed rocking member united to said connecting member, a cam-disk opposing the arms of said rocking member and provided with a sleeve, a casing member in which the sleeve of said cam member is fitted, and means for operating against said sleeve for adjusting said cam member relative to the arms of said rocking member, substantially as set forth.

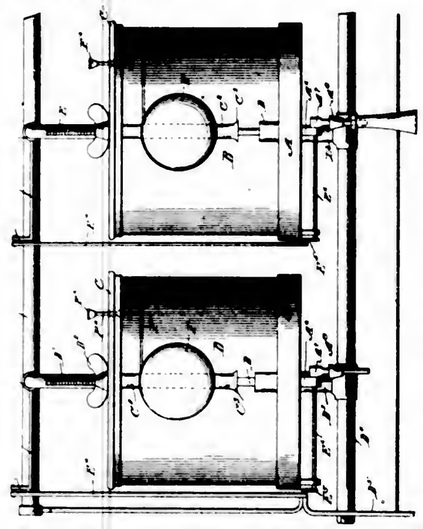
8. In a steering mechanism, the combination of a steering-wheel-connecting member, an armed rocking member united to said connecting member, a cam-disk opposing the arms of said rocking member and provided with a sleeve, a casing member in which the sleeve of said cam member is fitted, and a bearing-cap fitted to said casing member and arranged to impart movement to said cam-disk through the medium of its sleeve, substantially as set forth.

9. In a steering mechanism, the combination of a steering-wheel-connecting member, an armed rocking member united to said connecting member, a cam-disk opposing the arms of said rocking member and provided with a sleeve, a casing member in which the sleeve of said cam-disk is fitted, a bearing-cap fitted to said casing member and arranged to impart movement to said cam-disk through the medium of its sleeve, and a jam-nut arranged to hold said bearing-cap, substantially as set forth.

10. In a steering mechanism, the combination of a steering-wheel-connecting member, a rocking member for actuating said connecting member, and a cam-disk for operating said rocking member having a rim at its edge and provided with an oil-duct located adjacent to said rim, substantially as set forth.

809,621. **BOTTLING-MACHINE.** ERNEST L. MILLER, Louisville, Ky. Filed Apr. 17, 1905. Serial No. 256,076.

Claim.—1. In a bottling-machine, a receptacle, a supply-pipe thereto provided with a valve having an operating-arm, a delivery-valve communicating with said receptacle and provided with an oscillating bottle-tube for operating the same, an operating-arm carried by said delivery-valve, and means extending directly between the arms upon said supply and delivery valves for operating them simultaneously by the movement of the bottle-tube in the insertion and withdrawal of a bottle.



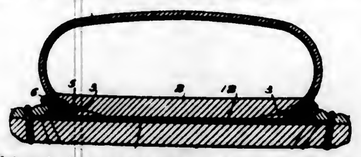
2. In a bottling-machine, a measuring-receptacle, a bottom plate upon which said receptacle rests, a top plate therefor, and means for adjusting said plates at different distances from each other to receive receptacles of different height or capacity.

3. In a bottling-machine, a measuring-receptacle, a bottom plate, a post extending upward therefrom, a top plate provided with a depending sleeve surrounding said post, a float slidably mounted upon said sleeve, and a valve carried by said float to close a vent-opening in said top plate.

4. In a bottling-machine, a measuring-receptacle, a bottom plate, a post extending upward therefrom, a top plate provided with a depending sleeve surrounding said post, a float slidably mounted upon said sleeve, a valve carried by said float to close a vent-opening in said top plate, a laterally-disposed arm carried by said float to support said valve, and a stop-flange at the lower end of said sleeve.

5. In a bottling-machine, a base-plate provided with a seat therein, a packing disposed upon said seat, a supply-pipe communicating with the bottom of said base, an open-ended receptacle seated upon said packing, a vertically-disposed post carried by said plate and provided with a threaded upper end adapted to extend above receptacles of different capacities, a top plate disposed at the upper end of said receptacle, and a holding-nut threaded upon said post to engage said top plate.

809,622. **SHOE.** JAMES N. MOULTON, Haverhill, Mass., assignor to The Waterproof Welt & Filler Co., Hartford, Conn., a Corporation of Delaware. Filed Mar. 14, 1905. Serial No. 249,994.



Claim.—1. A shoe comprising an upper, an inner sole having the usual channel in its bottom, a welt, an integral strip of yielding and elastic waterproof material lying between the welt and the upper, these parts being secured together by a row of stitches passing through the yielding and elastic strip and into the channel in the inner sole, whereby the elastic strip closes around the stitches as the shoe is sewed, thus making the structure waterproof, and an outer sole secured to the welt.

2. A shoe comprising an upper, an inner sole having the usual channel in its bottom, a welt, an integral strip of yielding and elastic waterproof material lying between the welt and the upper, these parts being secured together by a row of stitches passing through the yielding and elastic strip and into the channel in the inner sole whereby the elastic strip closes around the stitches as the shoe is sewed, thus making the structure waterproof, an outer sole secured to the welt, and a waterproof sole-filling material between the outer and the inner soles, the edge of the yielding and elastic strip lying closely in contact with the sole-filling material.

3. A shoe comprising an upper, an inner sole having the usual channel in its bottom, a welt, an integral strip of yielding and elastic waterproof material lying between the welt and the upper, these parts being secured together by a row of stitches passing through said strip and into the channel in the Inner sole, whereby said strip closes around the stitches as the shoe is sewed, thus making the structure waterproof, an outer sole secured to the welt, and a waterproof sole-filling material between the inner and outer soles, the edges of said material extending underneath the welt.

4. A shoe comprising an upper, an inner sole, a welt, an integral strip of waterproof filling material lying between the welt and the upper, said parts being secured together by a row of stitches, an outer sole secured to the welt, and a filling material having a relatively thick central portion and a relatively thin edge between the soles, the thin edge lying between the welt and the outer sole.

809,623. **WATERPROOF SOLE.** JAMES N. MOULTON, Philadelphia, Pa., assignor to John R. Reynolds, Hartford, Conn. Filed May 18, 1904. Serial No. 208,515.

Claim.—1. A waterproof protector and filler for welted shoes to be interposed between the inner and outer soles thereof, said protector including a body portion comprising a sheet of waterproof material and a filler-section attached thereto, and a relatively thin flexible waterproof edge, the thicker body portion serving as a filler for the cavity between the soles.

2. A waterproof protector and filler for welted shoes to be interposed between the inner and outer soles thereof, said protector comprising a sheet of rubber, a reinforcing-sheet and a filler-section, the filler-section being of a size to be contained within the cavity existing between the inner and outer soles and bounded by the edge of the welt and forming in connection with the rubber and the reinforcing-sheet a body portion, the rubber extending beyond the body portion and forming a thin flexible edge to overlie the seam by which the welt is secured to the upper and inner soles.

3. A waterproof protector and filler for welted shoes to be interposed between the inner and outer soles thereof, comprising a sheet of rubber, a filler-section secured to the sheet of rubber, said section being of a size to be contained within the cavity existing between the inner and outer soles, and a reinforcing-sheet on the side of the rubber sheet opposite to that on which the filler-section is mounted, the filler-section, rubber and reinforcing-sheet forming a body portion and the rubber and reinforcing-sheet extending beyond the body portion and forming a relatively thin flexible edge to overlie the seam by which the welt, upper and inner soles are secured together.

4. A shoe comprising an upper, an inner sole and a welt stitched together, an outer sole, and a waterproof protector or filler interposed between the inner and outer soles, said protector including a body portion comprising a sheet of waterproof material and a filler-section and a relatively thin flexible waterproof edge, the thicker body portion serving as a filler for the cavity between the soles, and the thin flexible waterproof edge serving to overlie the seam by which the welt, upper and inner sole are secured together.

5. A shoe comprising an upper, an inner sole and a welt stitched together, an outer sole, a waterproof protector and filler interposed between the inner and outer soles, said protector comprising a sheet of rubber, a reinforcing-sheet and a filler-section, the filler-section being contained within the cavity existing between the inner and outer soles and bounded by the edge of the welt, and forming in connection with the rubber sheet and the reinforcing-sheet a body portion, the rubber extending beyond the body portion and forming a

relatively thin flexible edge which overlies the seam by which the welt is secured to the upper and inner sole.

6. A shoe comprising an upper, an inner sole and a welt stitched together, an outer sole, a waterproof protector and filler interposed

a floor having a depression near each end and a vertical web at each side thereof extending beyond the ends of the floor, an inclined web extending in front and rear of the depression of the floor, and ribs connecting the inner end of the inclined web to the floor proper, all

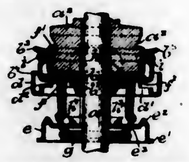
securing the plate to the arm, one side of said curved portion having a forwardly-turned elongated blade-supporting portion, means for adjustably holding the blade thereon, and the opposite edge of said curved portion having a laterally-turned portion engaging the blade and bracing the same.

close proximity to the lower end of the upper belt, sheaves arranged in about the same horizontal plane at a point adjacent to the horizontal median line of the door, an operating-shaft extending transversely through the door below the two last-mentioned sheaves, a lever fixed to and normally depending from the outer end of the shaft,

relatively thin flexible edge which overlies the seam by which the welt is secured to the upper and inner sole.

6. A shoe comprising an upper, an inner sole and a welt stitched together, an outer sole, a waterproof protector and filler interposed between the inner and outer soles, said protector comprising a sheet of rubber, a filler-section, said filler-section being secured to the sheet of rubber and being contained within the cavity existing between the inner and outer soles, and a reinforcing-sheet on the side of the rubber sheet opposite to that on which the filler-section is mounted, the filler-section, rubber sheet and reinforcing-sheet forming a body portion and the rubber and reinforcing-sheet extending beyond the body portion and forming a relatively thin flexible edge which overlies the seam by which the welt, upper and inner sole are secured together.

809,624. **BOBBIN-HOLDER.** THOMAS J. MURDOCK, Franklin, Mass., assignor to Murdock and Gob Company, Franklin, Mass. Filed Dec. 29, 1903. Serial No. 186,908.



Claim.—1. A bobbin-holder having a plurality of pivoted locking-jaws, an endless coiled spring, two spring-plates having clamping-arms formed integral therewith and held in contact with the locking-arms by the endless coiled spring, and means for operating the locking-jaws to firmly secure the bobbin in the holder when in the locked position, substantially as described.

2. A bobbin-holder having a plurality of locking-jaws for locking a bobbin-head in the holder, means for automatically opening or closing the locking-jaws, and two spring-plates having clamping-arms formed integral therewith and held in contact with the locking-jaws in their locked position by an endless coiled spring to firmly secure the bobbin-head in the holder.

3. A bobbin-holder having a plurality of locking-jaws, an operating-frame in connection with the locking-jaws, spring-plates provided with clamping-arms formed integral therewith and in contact with the locking-jaws, an endless coiled spring and bends in the locking-jaws acting as cams on the clamping-arms to assist the coiled spring to force the locking-jaws inward by a downward movement of a bobbin on the operating-frame to lock a bobbin-head in the holder, as described.

4. In combination, a bobbin-holder having a plurality of pivoted locking-jaws, a movable frame carrying the locking-jaws pivoted in the frame, an operating-frame in connection with the locking-jaws, a fixed frame, means for securing the fixed frame to a spindle, spring clamping-arms in the fixed frame in contact with the locking-jaws, bends in the locking-jaws acting as cams on the clamping-arms to force and lock the locking-jaws into a groove in the peripheral surface of the head of a bobbin, when the operating-frame is forced downward by the bobbin-head, and an endless spiral spring in connection with the lower ends of the locking-jaws below the pivots to open the jaws when the bobbin is moved upward, as described.

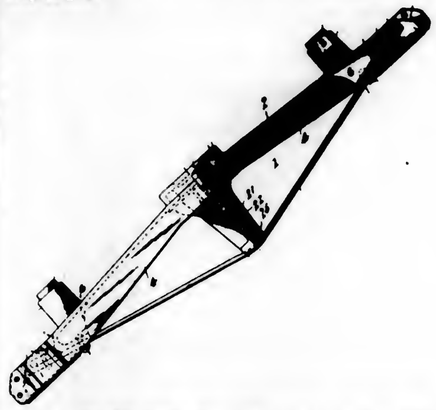
5. In combination with a bobbin-holder, clamping-arms stamped from sheet metal to form a plate b^3 with two clamping-arms b^3 b^3, apertures b^4 b^4, and a central opening b^5 for securing the plate b^3 in the holder, as described.

6. A bobbin-holder having a plurality of locking-jaws, a movable frame carrying the locking-jaws, the plate *e* provided with the thread-catching points e^3 and the lip e' and on which the locking-jaws are pivoted, a fixed frame, spring-plates provided with clamping-arms secured to the fixed frame, and an endless spiral spring in connection with the clamping-jaws, as described.

809,625. **CAR TRUCK-BOLSTER.** GEORGE C. MURRAY, Washington, D. C. Filed June 19, 1905. Serial No. 265,094.

Claim.—1. In a car truck-bolster, an integral cast-metal compression member having a floor and vertical side flanges extending at the ends of the bolster beyond said floor, a tension member embracing the ends of the floor and embraced between said flanges at the ends of the floor, and separate spring-seats secured to both said members and lying between the vertical flanges.

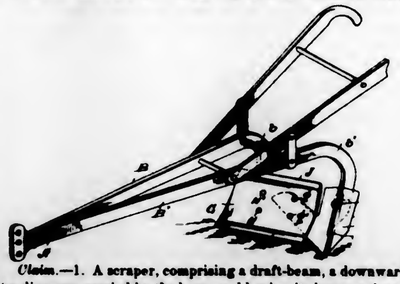
2. In a car truck-bolster, the compression member consisting of a floor having a depression near each end and a vertical web at each side thereof extending beyond the ends of the floor, an inclined web extending in front and rear of the depression of the floor, and ribs connecting the inner end of the inclined web to the floor proper, all being integral.



3. In a car truck-bolster, the combination of a cast-metal compression member having a floor with depressions near the ends and inclined webs under the same, a central king-post, and a tension member secured in the depressed portion of the floor, passing round the inclined webs, and under the king-post, and secured to said inclined web.

4. In a car truck-bolster, the combination with a compression member having side webs and an inclined web near its ends, and a tension member folded round said inclined web between the side webs, of a detachable spring-seat secured between said side webs and having a flange extending under said side webs.

809,626. **COMBINED SCRAPER AND SHOVEL-PLOW.** NEAL MCLAUGHLIN, Jethro, Ark. Filed May 15, 1905. Serial No. 260,596.



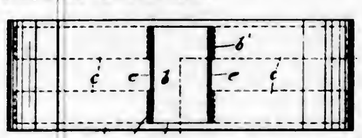
Claim.—1. A scraper, comprising a draft-beam, a downwardly-extending arm carried by the beam and having its lower end rounded, a blade-supporting member having a curved portion corresponding to the curve of the beam, means for clamping said plate on the arm, means carried by the plate for securing the blade thereto, and a forwardly-turned portion carried by the curved portion of the plate for engaging and bracing the blade.

2. A scraper, comprising a draft-beam, a downwardly-extending arm carried by the beam and having its lower end rounded, a blade-supporting member having a vertically-disposed curved portion resting against the arm, and having a horizontal elongated slot therein, a bolt passing through the slot and clamping the plate to the arm, one side of said curved portion having a laterally-turned blade-supporting surface, means for adjustably holding the blade thereon, and the opposite edge of said curved portion having a laterally-turned portion engaging the blade and bracing the same.

3. A scraper, comprising a draft-beam, a downwardly-extending arm carried by the beam and having its lower end rounded, a blade-supporting member having a vertically-disposed curved end corresponding to the rounded end of the arm and resting against the same, and having a horizontal elongated slot therein intermediate the upper and lower ends; a bolt passing through the slot and arm and

securing the plate to the arm, one side of said curved portion having a forwardly-turned elongated blade-supporting portion, means for adjustably holding the blade thereon, and the opposite edge of said curved portion having a laterally-turned portion engaging the blade and bracing the same.

809,627. **BRAKE-SHOE.** WILLIAM H. NAHACK, Ballston, N. Y. Filed May 2, 1905. Serial No. 258,460.



Claim.—1. A brake-shoe comprising a body, and a lug having longitudinal and transverse openings therein and provided with imperforate portions extending longitudinally of and embedded in said body.

2. A brake-shoe comprising a body, and a lug having longitudinal and transverse openings therein and provided with portions thereof embedded in said body, the parts being so constructed and arranged that the material which forms the body surrounds and covers certain portions of the lug and enters between imperforate parts of the same.

3. A brake-shoe comprising a body, and a lug having longitudinal and transverse openings therein and consisting in part of bifurcated portions partially embedded in said body.

4. A brake-shoe comprising a cast-metal body, and a lug of stronger material having longitudinal and transverse openings therethrough and provided with bifurcated portions embedded in said body.

5. As a new article of manufacture, a brake-shoe lug consisting of a top portion, side pieces extending from such portion, and a plurality of arms extending from said side pieces, the latter being at right angles to the longitudinal direction of said arms.

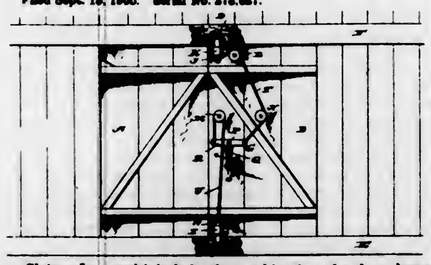
6. As a new article of manufacture, a brake-shoe lug consisting of a top portion, a plurality of side pieces springing from the lateral edges of said top portion, and a plurality of arms extending outward from the bases of said side pieces.

7. A brake-shoe comprising a body, and a lug consisting of a top portion, a plurality of side pieces springing from the lateral edges of said top portion, and a plurality of arms extending outward from the bases of said side pieces, said arms being embedded in said body.

8. A brake-shoe comprising a flanged body, and a lug consisting of a top portion, side pieces extending from such portion, a plurality of arms extending from said side pieces, the latter being at right angles to the longitudinal direction of such arms, and a wing projecting from one of said arms, the arms and wing being embedded in said body and its flange.

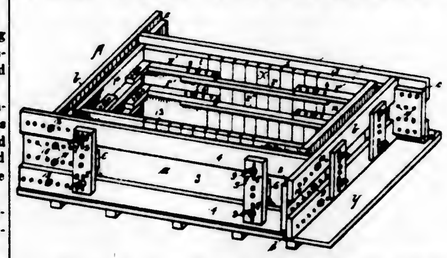
9. A brake-shoe comprising a body having a flange on one side, and a lug consisting of a top portion, a plurality of side pieces springing from the lateral edges of said top portion, a plurality of arms extending outward from the bases of said side pieces, and wings projecting from the edges of said arms which are adjacent said flanges, the arms being embedded in said body and said wings in the flange.

809,628. **MULTIPLE BOLT.** JOHN H. PRETSMAN, Greenville, Ohio. Filed Sept. 15, 1905. Serial No. 278,087.



Claim.—In a multiple bolt, the combination of a door, lower and upper vertically-movable bolts arranged in guides on the inner side of the door, a sheave mounted on the inner side of the door in close proximity to the lower end of the upper bolt, sheaves arranged in about the same horizontal plane at a point adjacent to the horizontal median line of the door, an operating-shaft extending transversely through the door below the two last-mentioned sheaves, a lever fixed to and normally depending from the outer end of the shaft, a T-lever having a head fixed at its middle on the inner end of the shaft and also having a pendent stem, a cable passed around the first-mentioned sheave and one of the other sheaves and connecting the lower end of the upper bolt and one end of the head of the T-lever, and a cable passed over the remaining sheave and connecting the opposite end of the head of the T-lever and the upper end of the lower bolt.

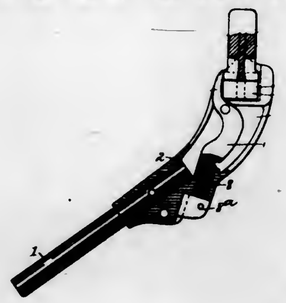
809,629. **BURIAL-VAULT MOLD.** JOHN M. PRUETT and JACOB C. SIMPSON, Rockville, Ind. Filed June 21, 1905. Serial No. 266,231.



Claim.—1. In an adjustable burial-vault mold, the combination of an adjustable outer form, composed of four independent walls, adapted to be assembled together in various positions, to render various-sized forms, suitable bolts adapted to hold said walls together with an adjustable inner form, consisting of four separate and independent walls, adapted to be assembled together in various positions to render various-sized forms, backs and bolts adapted to fasten the respective corners of the said form together, a cover-form consisting of four separate and independent walls adapted to be assembled together in various positions to render various sizes of cover-forms, and means of holding said walls in assemblage and one or more angular dividing-strips adapted to fit into the cover-form, all substantially as shown and described and for the purpose set forth.

2. In an adjustable and collapsible burial-vault mold, the combination of an outer form, comprising four separate walls composed of a main panel, two adjustable molding-strips movably attached thereto, and two cleats attached to the main panel and adapted to adjustably retain the molding-strips, and means of fastening said walls together, with an adjustable inner form comprising four separate adjustable walls, composed of a series of perpendicular panels adjustable three-piece extension-rails, means of attaching said extension-rails to said panels and corner-blocks adapted to unite abutting walls thereof, said outer and inner forms being adapted to be spaced relatively one to the other, and an adjustable cover-form comprising four separate walls, adapted to be assembled together in various positions, relatively, to each other, one or more angular dividing-strips adapted to fit into the cover-form, all substantially as described and for the purpose set forth.

809,630. **TROLLEY ATTACHMENT.** EDWARD D. ROCKWELL, Bristol, Conn. Filed May 17, 1905. Serial No. 260,766.



Claim.—1. A trolley-harp arranged to removably receive a trolley-wheel, and an emergency-contact arranged to replace said wheel and to be held against rotation by the wheel-retaining means.

2. A trolley-harp arranged to removably receive a trolley-wheel, an emergency-contact having an upwardly-extending part provided with a groove for the reception of a trolley-wire, and supports extending laterally from the contact and arranged to be received by the wheel-retaining means.

3. An emergency-contact made of metal and having an upwardly-projecting part providing a groove for the reception of a trolley-wire, laterally-extending supports therefor and guards to prevent interference of a trolley-wire.

4. In combination with a trolley-harp having arms at its outer end arranged to removably receive a trolley-wheel, an emergency-contact arranged to replace said wheel and to be entirely held and supported on said arms by the wheel-retaining means.

5. In combination with a trolley-harp having side arms with grooves therein for removably receiving a trolley-wheel, an emergency-contact arranged to replace said wheel and be held against rotation by said grooves.

6. In combination with a trolley-harp having side arms with grooves therein for removably receiving a trolley-wheel, an emergency-contact arranged to replace said wheel and be supported and held against rotation by means of said grooves.

7. In combination with a trolley-harp having side arms with grooves therein for removably receiving a trolley-wheel, an emergency-contact arranged to be supported and held against rotation by means of said grooves, said contact having an upwardly-projecting part with a groove for the reception of a trolley-wire.

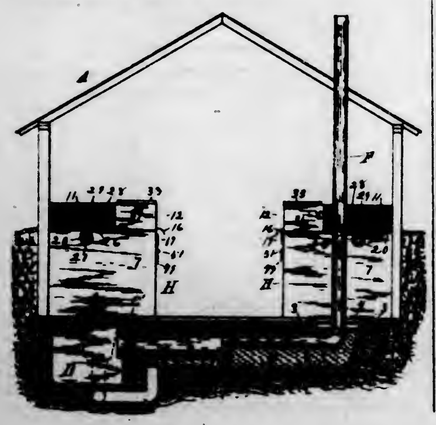
8. In combination with a trolley-harp having side arms with grooves therein for removably receiving a trolley-wheel, an emergency-contact arranged to replace said wheel, supports extending laterally from the contact and arranged to be received by said grooves, and guards to prevent interference of a trolley-wire.

9. In combination with a trolley-harp having side arms with grooves arranged therein, means for closing the open ends of said grooves, and an emergency-contact non-rotatably held and supported by means of said grooves, and an upwardly-projecting part provided with a groove for the reception of a trolley-wire.

10. In combination with a trolley-harp having side arms each provided with angularly-shaped grooves, means for closing the entrance to said grooves, an emergency-contact non-rotatably held by means of laterally-extending, angularly-shaped supports located in said grooves, the contact having an upwardly-extending part with a groove for the reception of a trolley-wire.

11. In combination with a trolley-harp having branching arms each provided with an angularly-shaped groove, means for closing the entrance to said groove, and an emergency-contact having laterally-extending, angularly-shaped supports to fit the grooves in said harp, an upwardly-projecting part having a groove for the reception of a trolley-wire, and laterally-extending guards or wings to prevent interference of a trolley-wire.

809,631. BROODER. NATHANIEL SALTONSTALL, Battlecreek, Mich. Filed Mar. 11, 1904. Serial No. 197,615.



Claim.—1. The combination of a continuous series of brooders having warm-air compartments formed beneath them, a heating-chamber located beneath said compartments and hermetically sealed therefrom, timbers arranged upon said hermetically-sealed compartments to form an inclosing framework, doors hinged to said timbers above said hermetically-sealed compartments to form a separate dead-air chamber, means for adjusting said doors, and doors opening into said compartments, substantially as set forth.

2. The combination of a continuous series of brooders having warm-air compartments formed beneath them, said brooders comprising an inclosure within an outer housing, ventilators leading from the exterior and communicating with said compartments, traps provided for said ventilators, and ventilators communicating between said warm-air compartments and the surrounding housing, and a heating-chamber located beneath said compartments and hermetically sealed therefrom, substantially as, and for the purpose set forth.

3. The combination of a continuous series of brooders having warm-air compartments formed beneath them, said brooders comprising an inclosure within an outer housing, the forward end thereof forming a hover connectively united at its sides with said housing by wire lattice, doors opening from said housing into said inclosures and means for opening and closing said doors, substantially as set forth.

4. A hover mounted upon a warm-air compartment, the flooring of said hover comprising in part a thin metallic heat-radiating surface, the top and ends of said hover being transparent, said top being detachable and its ends capable of vertical adjustment, for the purpose set forth.

5. A hover mounted upon a warm-air compartment, a removable transparent top covering, and vertically-adjustable end doors, coil-springs attached at one end thereof to the inner walls of said hover, their opposite ends being attached to said doors, spurs at either inner end of said doors, and apertures alined therewith in the ends of said side walls adapted to engage said spurs and prevent said doors from sliding on their bearings, substantially as set forth.

6. The combination with a brooder, of side walls having their bottoms rabbeted to form grooves along either side of the flooring thereof, a pocket arranged at one end of the brooder beneath the flooring thereof, a paper coil operative within said pocket, a covering to said pocket arranged to permit the placing of said coil within said pocket and also arranged to permit the unwinding of said coil over said flooring from the opposite end of the brooder through said grooves of the side walls, substantially as, and for the purpose set forth.

7. The combination with heating-chambers, of brooders continuously alined on the covering to said chambers, longitudinal pockets alined along the rear edge of said covering within said brooders, paper coils operative within said pockets, coverings to said pockets arranged to permit the unwinding of said paper coils from the forward end of said brooders, all arranged to work substantially as, and for the purpose set forth and described.

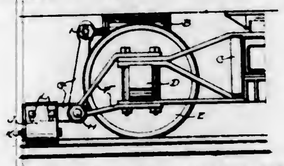
8. The combination with a housing, of brooders located within said housing, means for heating said brooders, said brooders comprising inclosures one end of which comprises a sash formed within said housing and provided with double transparent glass, openings within said sash, transparent doors hinged at their upper edges within said openings and adapted to open inwardly, said doors having notches at their lower edges, wire lattice at either side of said sash, a hover united at either side to said inclosure, for the purpose set forth.

9. The combination with a housing, of brooders located within said housing, means for heating said brooders, said brooders comprising inclosures one end of which comprises a sash formed within said housing and provided with double transparent glass, openings within said sash, transparent doors hinged at their upper edges within said openings and adapted to open inwardly, said doors having notches at their lower edges, wire lattice at either side of said sash, a hover united at either side to said inclosure, said hovers comprising opaque sides a removable transparent top and vertically-adjustable ends, substantially as, and for the purpose set forth.

10. The combination with heating-chambers, of brooders alined on the coverings to said chambers, said brooders comprising rearward inclosures encompassed at the rear ends by sash having transparent glass provided with openings having overhung doors provided with notches in their lower edges, adapted to swing inwardly; at the sides by wire lattice; at their forward ends by hovers comprising opaque sides, removable transparent tops and vertically-adjustable transparent end doors, substantially as, and for the purpose set forth.

11. The combination with heating-chambers of brooders alined on the covering to said chambers, said brooders comprising a rearward inclosure encompassed at one end by a transparent double-glass sash having an inwardly-opening door with a notch at its lower side; at the side by wire lattice-work and at the forward end by a hover comprising opaque sides, a removable transparent top and vertically-adjustable ends, the forward part of the flooring to said hovers consisting of a thin metallic plate, a pocket in the rear end of said brooders, a coil of paper in said pocket adapted to be unwound from the front end of said hover, and means for retaining said paper coil in said pocket, substantially as, and for the purpose set forth.

809,632. ANCHOR EMERGENCY AIR-BRAKE. CHARLES Z. SANDERS, Sacramento, Cal. Filed May 1, 1905. Serial No. 258,427.



Claim.—1. In a car, the combination with a truck-frame, of two yokes, each having bifurcated arms secured to the top and bottom of said truck-frame, said yokes having their convergent arms terminating in an enlarged portion, a fulcrum-shaft supported in said enlarged portions, a bell-crank lever fulcruming on said shaft, a brake-shoe carried by one arm of the lever, and connection with a source of power by the other arm of said lever, substantially as set forth.

2. The combination with a truck-frame, of a yoke having bifurcated arms secured to the top and bottom of said frame, a fulcrum-shaft carried by said yoke, a bell-crank lever mounted on said shaft, a brake-shoe carried by one of the arms of said lever, and means connected with the other arm of the lever to operate the latter and the shoe, substantially as set forth.

3. In a car, the combination with a truck-frame, of two yokes carried by said frame, a fulcrum-shaft supported by said yokes, a bell-crank lever mounted on the fulcrum-shaft, a brake-shoe on one arm of the lever and means connected with the other arm to operate the lever, substantially as set forth.

4. In a car, the combination with a truck-frame, of two yokes carried by said frame, a fulcrum-shaft supported by said yokes, a bell-crank lever mounted on the fulcrum-shaft, a brake-shoe on one arm of the lever, a pressure-cylinder on the car, and a piston-rod therefor connected with the other arm of the lever, to operate the latter, substantially as set forth.

5. In a car the combination with the truck-frame, of a hanger thereon, a bell-crank lever fulcrumed on the hanger, a brake-shoe to engage the rail carried by one arm of the lever, and pressure means connected with the other arm of the lever to operate the latter, said brake-shoe having hinged movable sections to grip the opposite sides of the rail, substantially as set forth.

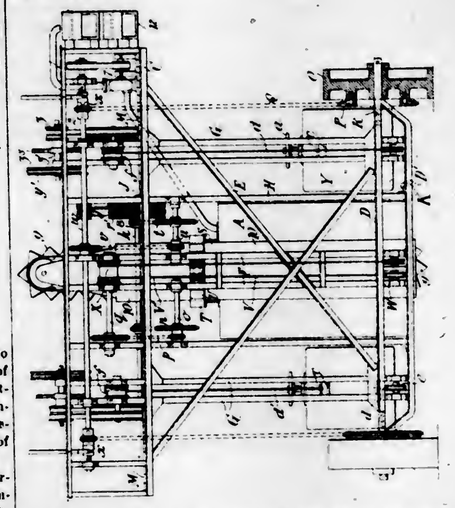
6. In a car the combination with the truck-frame, of a hanger thereon, a bell-crank lever fulcrumed on the hanger, a brake-shoe to engage the rail carried by one arm of the lever, pressure means connected with the other arm of the lever to operate the latter, said brake-shoe having hinged movable sections to grip the opposite sides of the rail, said lever having a limited movement independent of said clamp-sections, substantially as set forth.

7. In a car the combination with the truck-frame of a hanger thereon, a bell-crank lever fulcrumed on the hanger, a brake-shoe to engage the rail carried by one arm of the lever, pressure means connected with the other arm of the lever to operate the latter, said brake-shoe having hinged movable sections to grip the opposite sides of the rail, said lever having a limited movement independent of said clamp-sections, and means for maintaining said clamp-sections normally out of contact with the rail, substantially as set forth.

8. In a car, a suitably-fulcrumed bell-crank lever, having one of its members wedge shape, in cross-section, a sectional clamp-shoe carried by said arm, the incline surface of said arm engaging corresponding surfaces on said sections to operate the latter clamp fashion, and means to rock the lever, substantially as set forth.

809,633. SUBMARINE MINING. EDGAR F. SCHEIBE, New York, N. Y., assignor, by direct and mesne assignments, to Submarine Gold Mining Company, a Corporation of New York. Filed Mar. 1, 1905. Serial No. 247,904.

Claim.—1. In combination, a support arranged to rest on the bottom, and a caisson supported thereby and adapted to extend to the bottom to permit expulsion of the water therefrom within the area of the caisson.



2. In combination, a support arranged to rest on the bottom, and a caisson supported thereby and vertically movable relatively thereto and adapted to extend to the bottom to permit expulsion of the water therefrom within the area of the caisson.

3. In combination, a support arranged to rest on the bottom, a caisson supported thereby and vertically movable relatively thereto, and guides for said caisson carried by said support.

4. In combination, a support arranged to rest on the bottom, a caisson supported thereby, and a cable attached to said caisson and passing downward to a lower point of said support whereby the caisson may be pulled down.

5. In combination, a support arranged to rest on the bottom, a caisson supported thereby and adapted to extend to the bottom to permit expulsion of the water therefrom within the area of the caisson, and means for moving said support along on the bottom.

6. A caisson provided with means for moving it along while supported on the bottom and adapted to extend to the bottom to permit expulsion of the water therefrom within the area of the caisson.

7. In combination, a support arranged to rest on the bottom, a caisson supported thereby, and a tank carried by said support and adapted to be filled or emptied to be used as a weight or as a float.

8. In combination, a support arranged to rest on the bottom, a caisson supported thereby, and a tank carried by said support and adapted to be adjusted vertically on said support.

9. In combination, a support arranged to rest on the bottom, a caisson supported thereby, and a platform at the top of said support so as to be ordinarily out of reach of waves.

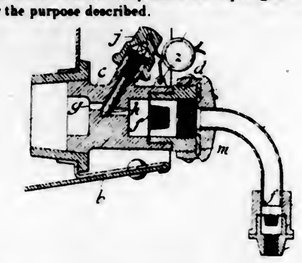
10. In combination, a support arranged to rest on the bottom, a caisson supported thereby, and a sand-elevator passing outside of the caisson to a point approximately level with the lower edge of the caisson.

11. In combination, a caisson and a sand-elevator attached to the outside of said caisson so as to be lowered therewith and having its lower end approximately level with the lower edge of the caisson.

809,634. SAFETY-SPOUT FOR RECEPTACLES CONTAINING VOLATILE INFLAMMABLE LIQUIDS. LUDWIG SCHÖN, Vienna, Austria-Hungary. Filed Mar. 14, 1901. Serial No. 51,208.

Claim.—1. In safety bungs and taps or spouts for receptacles for volatile inflammable liquids, the combination with the orifice of an outwardly-projecting neck, and a wire-gauze diaphragm inserted into the outer end of the neck, the said diaphragm having, in the clear of the neck, a ring-shaped, plane, marginal portion and a shallow cup-shaped central portion, substantially as and for the purpose described.

2. In a safety-tap for receptacles for volatile inflammable liquids, the combination with the tap-hole of an outwardly-projecting neck, a wire-gauze diaphragm inserted into the outer end of the neck, a spout adapted to be secured to the neck, a wire-gauze diaphragm inserted into the outer end of the spout, and a valve adapted to close the said neck between the receptacle and diaphragm, substantially as and for the purpose described.



809,685. CAR JOURNAL-BOX. JOHN R. SCHRADER, Buffalo, N. Y. Filed Dec. 5, 1904. Serial No. 235,467.

Claim.—1. In a car journal-box, the combination with the body thereof and a car-axle, of a bearing-block provided with an oil-pocket in its curved under side, an opening leading through the block from said pocket to the top thereof, and a groove in the top of said block which communicates with the opening and terminates at the block end over the axle, whereby the rotation of the car-axle fills the oil-pocket and forces oil through the opening to the top whence it flows through the groove to its termination and then downward by gravity upon the car-axle to produce an automatic overhead oil-feed, substantially as set forth.

2. In a car journal-box, the combination with the body thereof and a car-axle, of a bearing-block provided with a series of oil-pockets in its curved under side, and a groove in its side connected by openings with said oil-pockets: said groove extending to one end of the block over the axle whereby oil is conducted to the end of the bearing-block over the car-axle, for the purposes specified.

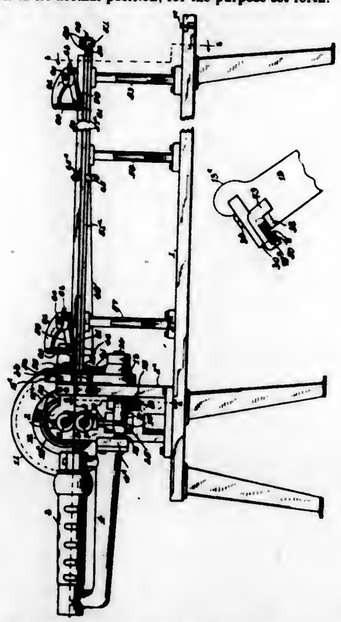
3. In a car journal-box, the combination with the body thereof and a car-axle, of a bearing-block provided with a series of oil-pockets in its curved under side, a plurality of grooves in its top side extending to at least one end of said bearing-block and over the axle whereby the oil may drop by gravity upon the axle, and openings extending from the oil-pockets to the grooves, whereby when the car is traveling the rotation of the axle will force oil into the recesses and up through the openings into the top grooves thereby producing an automatic overhead feed directly upon the car-axle.

4. In a car journal-box, the combination with the body thereof and the car-axle, of a bearing-block upon said axle having a longitudinal series of enlarged pockets on its under curved side, one or more grooves in the top of said block extending the full length thereof and vertical channels connecting said enlarged pockets with the groove or grooves whereby the axle is adapted to pick up oil from the box and to convey it to the pockets and thence through the channels to the aforesaid groove or grooves from which latter the oil returns by gravity to lubricate the axle.

809,686. WIRE STRAIGHTENING AND CUTTING-OFF MACHINE. FRANKLIN B. SHUMAN, New Haven, Conn. Filed Nov. 24, 1903. Serial No. 182,846.

Claim.—1. The combination, in a machine of the character described, comprising a head, a driving-shaft journaled therein, a wire-feed roll mounted thereon, a second wire-feed roll in close proximity to the wire-feed roll of the driving-shaft, said driving-shaft carrying a driving-pulley and cam, a cutter-holder reciprocally supported in close proximity to said head, a driving-pin operatively mounted in said holder and adapted to be engaged by said cam to actuate said holder to sever a section of wire, for the purpose set forth.

2. The combination, in a machine of the character described, comprising a head, a driving-shaft, carrying a wire-feed roll, journaled therein, a second wire-feed roll mounted in said head, said shaft carrying a driving-pulley and cam, a cutter-holder reciprocally supported in close proximity to said head, a driving-pin operatively mounted in said holder to be engaged by said cam to actuate said holder forward to sever a wire section, a spring to serve as a shock-arrester when the wire is being severed and also to return the holder to its normal position, means for locking the driving-pin when said holder is in its normal position, for the purpose set forth.



3. The combination, in a machine of the character described, comprising a head, a driving-shaft carrying a wire-feed roll, a cam and a driving-pulley, a second wire-feed roll journaled in a box located in said head, said box adapted to be tilted so that the second roll is carried to and from the first-named roll, a weighted lever fulcrumed in said head and in contact with said box, a cutter-holder reciprocally supported in close proximity to said head, a driving-pin operatively mounted in said holder to be engaged by said cam to actuate the holder to cut a section of wire, means on said holder to actuate the weighted lever and permit the said second wire-feed roll to temporarily drop away from the wire after a section has been severed therefrom, means for returning said cutter-holder and its driving-pin to their normal positions, for the purpose set forth.

4. The combination, in a machine of the character described, comprising a head, a reciprocating cutter-holder, a cam for actuating said holder to sever a section of wire, an adjustable stop against which said holder rests when in its normal position and to adjust the position of the cutter with respect to the cutting-die, for the purpose set forth.

5. The combination, in a machine of the character described, comprising a head, a driving-shaft journaled therein, wire-feed rolls one of which is mounted on said shaft together with a driving-pulley and a cam, said head having a wire-cutting die, a reciprocating cutter-holder carrying a cutter, a driving-pin operatively mounted in said holder to be engaged by said cam to actuate said holder to sever a section of wire, means on said cam to carry said pin out of engagement with that portion of the cam that actuates said holder to cut the wire, a locking-bolt to retain said pin in its normal position, a trip-wire to actuate said bolt, for the purpose set forth.

6. In a machine of the character described, a cutter-holder, a driving-pin carried by said holder operatively mounted therein, a cam to engage said pin to actuate said cutter-holder, for the purpose set forth.

7. The combination, in a machine of the character described, comprising a cutter-holder carrying a driving-pin operatively mounted therein, a cam to engage said pin to actuate said holder to cut a section of wire, an adjustable stop to engage said holder when not in action, for the purpose set forth.

8. The combination, in a machine of the character described, comprising a head carrying feed-rolls and cutting-dies, a driving-shaft carrying a driving-pulley and cam, a cutter-holder carrying a cutter and a spring-actuated driving-pin, said pin engaged by the cam to actuate said holder forward to sever a section of wire, a spring to act both as a buffer for the holder in its forward movement and to return it to its normal position, a stop to limit its backward movement, a locking-bolt for said driving-pin, a trip-wire, means for connecting said wire with the locking-bolt to release the driving-pin, for the purpose set forth.

9. In a machine of the character described, a reciprocating cutter-holder, a driving-pin operatively mounted therein, a cam to engage said pin to actuate said holder to cut a section of wire, a projection on said cam to return the pin to its normal position and means for temporarily locking it in such position, for the purpose set forth.

10. The combination, in a machine of the character described, comprising a head carrying feed-rolls, one of which rolls is mounted on a shaft journaled in a movable support, a weighted lever engaging said support, a cutter-holder reciprocally supported in close proximity to said head, means on said holder to actuate said weighted lever and temporarily release one of said feed-rolls from its engagement with the wire, for the purpose set forth.

11. The combination, in a machine of the character described, comprising a head, feed-rolls mounted on shafts, one of said shafts journaled in the head, the other shaft journaled in a tilting box located in said head, a manually-operated adjusting-block to engage said box and maintain its roll in feeding engagement with the wire, for the purpose set forth.

12. The combination, in a machine of the character described, comprising a guide-bar having a longitudinal groove therein to receive the wire, a supporting-bar for said guide-bar, a support for said supporting-bar, the grooved face of said guide-bar resting on its supporting-bar, said guide-bar adapted to have a lateral sliding movement on its supporting-bar to discharge a section of wire therefrom, for the purpose set forth.

13. The combination, in a machine of the character described, comprising a guide-bar having a longitudinal groove in one of its faces, a supporting-bar, the grooved face of the guide-bar operatively resting thereon, a reciprocally-operating cutter-holder to engage and move the guide-bar laterally on its support to discharge a section of wire therefrom, for the purpose set forth.

14. The combination, in a machine of the character described, comprising a guide-bar having a longitudinal groove therein to receive the wire, a supporting-bar, the grooved face of the guide-bar resting thereon, a reciprocally-operating cutter-holder to engage and move the guide-bar laterally on its support to discharge a section of wire therefrom, means connected with said bar to maintain its parallelism with its supporting-bar throughout its entire length, for the purpose set forth.

15. The combination, in a machine of the character described, comprising a guide-bar having a longitudinal groove in one of its faces to receive the wire, a support for said bar, said grooved face resting on said support, a reciprocating cutter-holder to engage said bar to actuate it laterally on its support to discharge a section of wire, means for maintaining the parallelism of said bar with its support, means for returning said bar to its normal position, for the purpose set forth.

16. The combination, in a machine of the character described, comprising a guide-bar having a longitudinal groove in one of its faces to receive the wire, a support for said bar with said grooved face resting thereon, said bar adapted to have a lateral sliding movement on its support and parallel therewith, for the purpose set forth.

17. In a machine of the character described, a guide-bar having a longitudinal groove in one of its faces for the wire, a stationary supporting-bar on which said guide-bar is slidably mounted to move laterally, for the purpose set forth.

18. The combination, in a machine of the character described, comprising a guide-bar for the wire, a support for said bar, a reciprocating cutter-holder, adjustable means on said holder to engage said bar to actuate it laterally on its support to discharge a section of wire therefrom, means for maintaining the parallelism of said bar with its support, means for automatically returning said bar to its normal position, for the purpose set forth.

19. The combination, in a machine of the character described, comprising a guide-bar having a longitudinal groove in one of its faces to receive the wire, a support for said bar, said bar adapted to have a lateral sliding movement thereon and parallel therewith, a clamp adjustably secured to said support, an overhanging lip of said clamp embracing the upper surface of the bar to prevent its lifting from its support, for the purpose set forth.

20. The combination, in a machine of the character described, comprising a guide-bar having a longitudinal groove in one of its faces, a support for said bar, means for actuating said bar laterally on its support, links having one of their ends pivotally supported adjacent to said bar, the other ends on said bar whereby the parallelism of said bar with its support is maintained when said guide-bar is in motion, means for automatically returning the guide-bar to its normal position, for the purpose set forth.

21. The combination, in a machine of the character described, comprising a guide-bar for the wire, a stationary supporting-bar therefor, means for effecting a lateral sliding movement of the guide-bar on its supporting-bar, means for maintaining the parallelism of the guide-bar with its supporting-bar, and means for automatically returning said guide-bar to its normal position, for the purpose set forth.

22. The combination, in a machine of the character described, comprising a guide-bar for the wire, a supporting-bar therefor, wire-receiving brackets on which said supporting-bar rests, means for actuating said guide-bar laterally on its supporting-bar, links pivotally supported on said brackets and guide-bar whereby said bars are maintained in parallel alinement with each other, arms adjustably supported outside of said bars and carrying springs at their free ends to connect with the guide-bar to automatically effect the return of said bar to its normal position, for the purpose set forth.

23. The combination, in a machine of the character described, comprising a guide-bar for the wire, a supporting-bar therefor, means for actuating the guide-bar laterally on its supporting-bar, links pivotally supported adjacent to said bars and also on the guide-bars to maintain said bars in parallel relation with each other, a projection on said links adapted to engage said supporting-bar to maintain the engagement of said bars with each other, for the purpose set forth.

24. The combination, in a machine of the character described, comprising a guide-bar for the wire and a supporting-bar therefor, means for laterally actuating said guide-bar, a weighted lever pivotally supported adjacent to said guide-bar and also on the same to maintain both of said bars in parallel relation with each other and to automatically return said guide-bar to its normal position, for the purpose set forth.

25. The combination, in a machine of the character described, comprising a guide-bar and a supporting-bar therefor, means for actuating said guide-bar, a weighted lever pivotally supported adjacent to said bar and on the same to maintain both of said bars in parallel relation with each other, and to automatically return said guide-bar to its normal position, means on said lever to engage the supporting-bar to maintain said bars in contact with each other, for the purpose set forth.

26. The combination, in a machine of the character described, comprising a guide-bar having a longitudinal groove to receive the wire, a supporting-bar for said guide-bar, means for actuating said guide-bar laterally on its support, a second guide-bar and its supporting-bar in linear alinement with the first-named bars, means whereby both guide-bars move in lateral unison, means whereby all of said bars are maintained in parallel relation with each other, means for returning both guide-bars to their normal position, for the purpose set forth.

27. The combination, in a machine of the character described, comprising a guide-bar having a longitudinal groove to receive the wire, a supporting-bar for said guide-bar, a cutter-holder carrying a cutter, a driving-pin operatively mounted in said holder, a cam to actuate said holder through the medium of said driving-pin, a stop-rod located in the guide-bar groove, a trip-wire connected with said rod and adapted to release the driving-pin and bring it into engagement with the cam, means on said holder to engage with and actuate the guide-bar laterally on its supporting-bar to discharge a section of wire therefrom, for the purpose set forth.

28. The combination, in a machine of the character described, comprising a head having a cutting-die, a driving-shaft journaled in said head, feed-rolls, one of which rolls is mounted on said shaft, said shaft also carrying a driving-pulley and cam, a reciprocating cutter-holder carrying a cutter, a driving-pin operatively mounted in said holder, a guide-bar for the wire, a supporting-bar for said guide-bar, means on the holder to engage the guide-bar, means for locking the driving-pin in its normal or retreated position, means for releasing said pin to bring it in contact with the cam and by such contact to actuate the cutter-holder to sever a section of wire, and, by means of the engagement of said holder with the guide-bar, said bar is moved laterally on its support to discharge such severed sections, means for maintaining said bars in parallel relation with each

other, and means for automatically returning the guide-bar to its

the hub, all extending across the chamber from side to side, recesses

when the door is in a closed position the rock-arm occupies a posi-

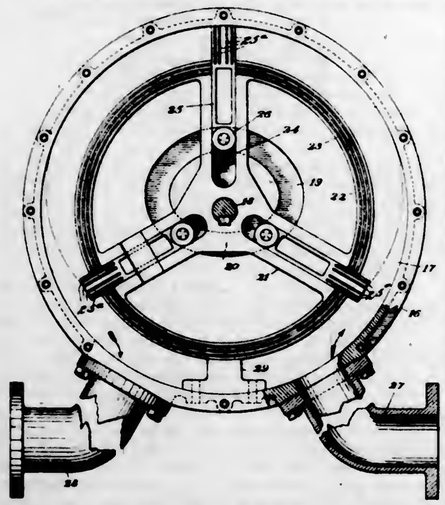
in direction of its length, and means for holding the said pin in different positions, thereby controlling the hammer movement.

other, and means for automatically returning the guide-bar to its normal position, for the purpose set forth.

29. The combination, in a machine of the character described, comprising duplicate guide-bars having longitudinal grooves to receive the wire, said bars operatively connected together, an independent supporting-bar for each of said guide-bars, means for actuating said bars on their supports, means for maintaining said guide-bars in parallel relation with their supporting-bars and in linear alinement with each other, and means for returning the guide-bars to their normal position.

30. The combination, in a machine of the character described, comprising feed-rolls having a plurality of circumferential grooves, a support for said rolls, a side wall, packing, substantially the thickness of one of said grooves interposed between said side wall and rolls to bring the first groove of the rolls in line with the wire, the second groove of the rolls being adapted to be brought in line with the wire by the removal of said packing, said rolls adapted to be reversed, for the purpose set forth.

809,637. **ROTARY MOTOR.** IRA H. SPENCER, Hartford, Conn., assignor to American Water Softener Company, Philadelphia, Pa., a Corporation of New Jersey. Filed Jan. 14, 1905. Serial No. 241,012.

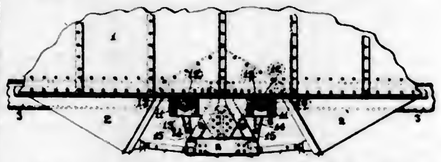


Claim.—1. In a fluid-motor, a shell having a cylindrical chamber communicating with supply and exhaust ports therefrom, with a cam-groove located in a wall of the chamber, a spider mounted to rotate in the chamber and including a rim forming the inner wall of the chamber with arms connecting the rim to the hub, and extending across the chamber from side to side and with piston-recesses formed on the outer face of each of said arms and extending through the rim, pistons having branches at each end thereof located in said recesses and engaging the wall of the shell, projections from said arms extending into the cam-grooves, and an abutment extending across the chamber.

2. In a fluid-motor, a shell having a cylindrical chamber communicating with supply and exhaust ports located therein with a cam located in a wall of the chamber, a spider mounted to rotate in the chamber and including a rim and arms connecting the rim and hub, all extending across the chamber from side to side, with recesses extending across the rim near the outer end of each of the arms and radially-extending recesses along opposite sides of each of the arms opening into the crosswise recesses, pistons having branches located in the recesses on opposite sides of the arms with their ends located in the crosswise recesses, said pistons extending across the chamber from side to side, projections from the branches on the pistons into the cam-groove, and an abutment extending across said chamber.

3. In a fluid-motor, a shell having a cylindrical chamber communicating with supply and exhaust ports located therein with a cam-groove in the wall of the chamber, a spider mounted to rotate in the chamber and including a rim and arms extending from the rim to the hub, all extending across the chamber from side to side, recesses extending through the rim and located on opposite sides of each of said arms, pistons each having branches located in the recesses on opposite sides of an arm, said pistons each extending across the chamber, concentric grooves formed in the edge of the rim, and grooves extending radially along the edges of said pistons.

809,638. **HOPPER-BOTTOM CAR.** JOHN S. STEVENSON, Detroit, Mich. Filed Apr. 1, 1905. Serial No. 253,323.



Claim.—1. In a hopper-bottom car, the combination with plate-girder side walls, a center sill, a central cross-ridge arranged between the plate-girder sides and above the plane of the center sill and a cross-beam carried by the plate-girder sides in a plane beneath the center sill, for supporting said center sill; substantially as described.

2. In a hopper-bottom car, the combination with hoppers, of a pair of doors closing the openings thereof, a beam having a channel of varying depths, the central part being the deepest, said beam being riveted to the lower edges of said doors, a cap-plate fastened to said beam at the point where the channel is deepest, and a door-operating mechanism connected to said beam between the doors; substantially as described.

3. The combination with a pair of hopper-doors, of a pressed-steel channel-shaped beam riveted to the lower edges thereof, a channel in said beam being of varying depths, the central part being the deepest, a cap-plate between the doors, and a spacer interposed between the cap-plate and the channeled portion of said beam; substantially as described.

4. The combination with a hopper-door, of a channeled beam riveted thereto, a cap-plate riveted to the beam, a pipe in the channel of said beam and in line with said cap-plate, a screw-eye having nuts impinging against the outer faces of said channel and said cap-plate, and a door-operating mechanism connected to said screw-eye; substantially as described.

5. The combination with a hopper-door, of a link pivotally connected thereto, rollers carried by said link, a fixed abutment with which the link coöperates when the door is closed, and guides for said rollers; substantially as described.

6. The combination with hopper-doors, of links pivotally connected thereto, rollers on the inner ends of said links, abutment-blocks against which the links rest when the doors are closed, beams 8 to which said abutment-blocks are riveted, and guides 9 riveted to the ends of said beams, said guides coöperating with said rollers; substantially as described.

7. The combination with center sills, of a cross-beam arranged thereunder, a transverse cross-ridge arranged above the center sills, hopper-doors hinged to the legs of said cross-ridge, longitudinally-disposed beams riveted to the under side of the cross-beam, abutment-blocks and guides on said last-mentioned beams, and links pivotally connected to the hopper-doors and coöperating with said abutment-blocks and guides; substantially as described.

8. The combination with a hopper-door, of a link pivotally connected thereto at one end, the opposite end of said link carrying rollers, and guides for said rollers, which guides have an oblique portion approximately parallel to the plane of the doors in their closed position; substantially as described.

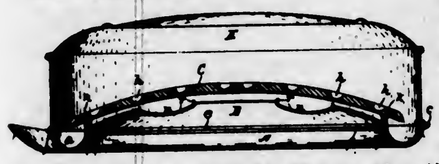
9. The combination with a hopper-door, of links pivotally connected thereto at one end, said links carrying rollers at their opposite ends, and a guide for said rollers, said guide having substantially vertical portions at its upper and lower extremities, and an intermediate obliquely-disposed portion; substantially as described.

10. The combination with a hopper-door, of an operating mechanism therefor comprising a rock-arm 14, links 15 and 17, rollers 16 at the pivotal connection between said links, channeled members 9 forming guides for said rollers, and an abutment-block; substantially as described.

11. The combination with a hopper-door, of a link pivotally connected thereto at one end, a guide for the opposite end of said link, another link pivotally connected to the guided end of said first-mentioned link, a rock-arm connected to said other link, whereby

when the door is in a closed position the rock-arm occupies a position of dead-center, and an abutment-block for supporting the guided end of said first-mentioned link when the door is closed; substantially as described.

809,639. **BROILER.** JOHN M. STOUER, Cleveland, Ohio, assignor to the Prince Stoker Oil Stove Company, Cincinnati, Ohio. Filed June 13, 1905. Serial No. 265,060.



Claim.—1. A broiler consisting of a metal ring and a grid mounted upon the ring, and a sheet-metal dome held by the ring beneath the grid, the dome and the grid being crowning with space between.

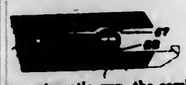
2. A broiler comprising a metal ring and a grid mounted thereon, and a sheet-metal dome upon the ring beneath the grid, the dome having slots with peripheral upwardly-projecting lips, the grid and the dome having a common seat upon the ring.

3. A broiler consisting of a ring or body having a flange and a horizontal circular ledge adjacent to the flange, and a grid upon the ring having a downwardly-projecting circular flange resting upon said ledge, and a sheet-metal dome having a peripheral flange adapted to rest upon said ledge between the flanges of the ring and the grid.

4. A broiler consisting of a ring or body having an upwardly-projecting circular flange *c* and a horizontal circular ledge at the base of the flange on its convex side, and a grid having a downwardly-projecting circular flange *k* adapted to rest upon the ledge, and a sheet-metal dome having a peripheral downwardly-turned flange adapted to rest upon said ledge between said opposing flanges *c k*, the opposing faces of said flanges *c k* and the flange of the dome all having an equal and similar slant.

5. A broiler consisting of a ring or body having an upwardly-projecting circular flange *c* and a horizontal circular ledge at the base of the flange on its convex side, and a grid having a downwardly-projecting circular flange *k* adapted to rest upon the ledge, and a sheet-metal dome having a peripheral downwardly-turned flange adapted to rest upon said ledge between said opposing flanges *c k*, the lower edge of the flange *k* in contact with the ledge being formed with a series of openings.

809,640. **GUN.** AUDLEY H. STOW, Hunter, W. Va. Filed Aug. 11, 1903. Serial No. 169,128.



Claim.—1. In an automatic gun, the combination of the hammer and means for cocking the same automatically, a sear, and a controlling-piece with which the hammer engages, to determine the hammer action.

2. In an automatic gun, the combination of the hammer, means for cocking the same automatically, a sear, and movable controlling-piece with which the hammer engages, to control the hammer action.

3. In an automatic gun, the combination of the hammer, means for cocking the same, a sear, and a controlling-pin having cross-sections of different form, each cross-section of the pin controlling the hammer action according to a predetermined system.

4. In an automatic gun, the hammer, means for cocking the same automatically, a trigger-sear, a trigger-sear trip, and a movable controlling-piece having a series of bearing-surfaces, each bearing-surface controlling the hammer to operate in a predetermined manner, all combined.

5. In an automatic gun, the combination of the hammer, means for cocking the same, a trigger-sear, a trigger-sear trip, and a movable controlling-pin having cross-sectional areas of different dimensions, and engaging the trigger-sear trip to determine the hammer action.

6. In an automatic gun, the hammer and means for cocking the same, a controlling-pin extending through the frame and movable in direction of its length, and means for holding the said pin in different positions, thereby controlling the hammer movement.

7. In an automatic gun, the hammer and means for cocking the same, the movable controlling-pin extending through the frame and varying in cross-section, a pawl on the hammer which pawl engages the sections of said pin to govern the hammer action according to the position of the controlling-pin, and means for holding the controlling-pin in adjusted position, all combined.

8. In a magazine-gun, a magazine, a vertically-movable carrier, a carrier-lever connected to said carrier, two pivots supporting said lever on variable fulcrums, and a spring acting to raise or lower said carrier according to the position of the bearing-fulcrum.

9. In a magazine-gun, the carrier, a carrier-lever pivotally connected thereto, a plurality of fulcrums on one or the other of which the carrier is supported, and a spring operating to both raise and lower the carrier, all combined.

10. In a magazine-gun, the combination of a carrier, a lever pivotally connected thereto, two pivot-pins projecting from the carrier-lever, a frame having two slots in which said pivot-pins may play, and a spring connected to the carrier-lever between said pins.

11. In a magazine-gun, the combination of a carrier, carrier-lever pivotally connected thereto, two pivot-pins projecting from said lever, and a spring connected to the lever between said pins, and slots in the frame in which said pins play, one of said slots having a shoulder on which the pin rests when in elevated position.

12. In a magazine-gun, the combination of a carrier, a carrier-lever pivotally connected thereto and supported on one or the other of two fulcrums, a spring connected to said lever between the fulcrums, the breech-bolt and a lever connected thereto; and a carrier-lever catch connected to said breech-bolt lever.

13. In a magazine-gun, a longitudinally-moving breech-bolt, a return-lever pivotally connected thereto, a vertically-moving cartridge-carrier and a carrier-lever pivotally connected thereto, variable fulcrums supporting said carrier-lever, and means connected with the return-lever by which the carrier-lever may be shifted on its fulcrums.

14. In an automatic gun, the combination of a cylindrical longitudinally-reciprocating breech-bolt, a vertically-moving carrier having a chamber neatly fitting said bolt and the cartridge-body used in the gun, and means for reciprocating the carrier, so that the backward-movement of the bolt permits the cartridge-shell to recoil into the carrier at the instant of firing.

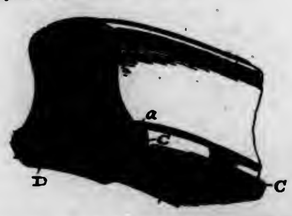
15. In an automatic gun, a vertically-movable cartridge-carrier having a cylindrical bore which receives the cartridge, a longitudinally-reciprocating breech-bolt which fits said bore, and means for closing the breech-bolt through the chamber in the carrier, and means for lifting the carrier so that its chamber is in line with the breech-bolt.

16. In a magazine-gun, the combination of a vertically-reciprocating carrier, the trigger, and a carrier-catch connected to and operated by the trigger.

17. In a magazine-gun, the combination of a vertically-reciprocating cartridge-carrier, a trigger, and a carrier-catch pivoted in the frame and connected to the trigger.

18. In a magazine-gun, the combination of a reciprocating bolt, a firing-pin carried thereby, a spring-actuated firing-pin catch in the breech-bolt having an inclined surface, and the hammer engaging said incline to release the firing-pin before striking it.

809,641. **VEHICLE-TIRE.** JAMES A. SWINEHART, Akron, Ohio. Filed Apr. 3, 1904. Serial No. 201,948.



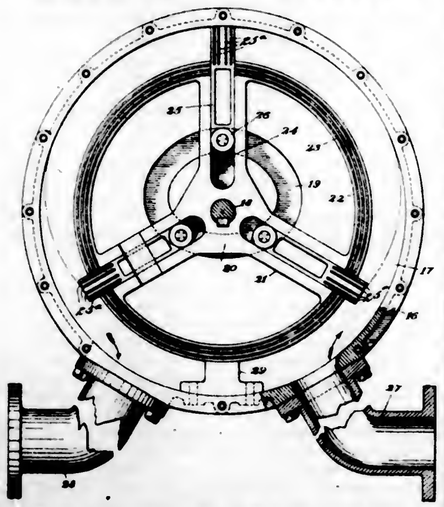
Claim.—1. In vehicle-tires, a metallic rim having opposite incurved edges about its periphery, in combination with a solid continuous rubber tire in said rim provided with side ribs engaged beneath said edges, a binding material interposed between said rim and tire and cemented to both, and cross-wires extending transversely

other, and means for automatically returning the guide-bar to its normal position, for the purpose set forth.

29. The combination, in a machine of the character described, comprising duplicate guide-bars having longitudinal grooves to receive the wire, said bars operatively connected together, an independent supporting-bar for each of said guide-bars, means for actuating said bars on their supports, means for maintaining said guide-bars in parallel relation with their supporting-bars and in linear alinement with each other, and means for returning the guide-bars to their normal position.

30. The combination, in a machine of the character described, comprising feed-rolls having a plurality of circumferential grooves, a support for said rolls, a side wall, packing, substantially the thickness of one of said grooves interposed between said side wall and rolls to bring the first groove of the rolls in line with the wire, the second groove of the rolls being adapted to be brought in line with the wire by the removal of said packing, said rolls adapted to be reversed, for the purpose set forth.

809,637. **ROTARY MOTOR.** IRA H. SPENCER, Hartford, Conn., assignor to American Water Softener Company, Philadelphia, Pa., a Corporation of New Jersey. Filed Jan. 14, 1905. Serial No. 241,012.

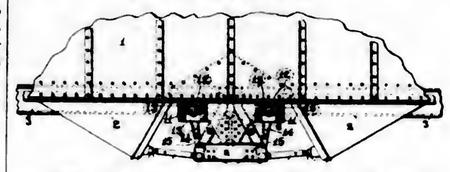


Claim.—1. In a fluid-motor, a shell having a cylindrical chamber communicating with supply and exhaust ports therefrom, with a cam-groove located in a wall of the chamber, a spider mounted to rotate in the chamber and including a rim forming the inner wall of the chamber with arms connecting the rim to the hub, and extending across the chamber from side to side and with piston-recesses formed on the outer face of each of said arms and extending through the rim, pistons having branches at each end thereof located in said recesses and engaging the wall of the shell, projections from said arms extending into the cam-groove, and an abutment extending across the chamber.

2. In a fluid-motor, a shell having a cylindrical chamber communicating with supply and exhaust ports located therein with a cam located in a wall of the chamber, a spider mounted to rotate in the chamber and including a rim and arms connecting the rim and hub, all extending across the chamber from side to side, with recesses extending across the rim near the outer end of each of the arms and radially-extending recesses along opposite sides of each of the arms opening into the crosswise recesses, pistons having branches located in the recesses on opposite sides of the arms with their ends located in the crosswise recesses, said pistons extending across the chamber from side to side, projections from the branches on the pistons into the cam-groove, and an abutment extending across said chamber.

3. In a fluid-motor, a shell having a cylindrical chamber communicating with supply and exhaust ports located therein with a cam-groove in the wall of the chamber, a spider mounted to rotate in the chamber and including a rim and arms extending from the rim to the hub, all extending across the chamber from side to side, recesses extending through the rim and located on opposite sides of each of said arms, pistons each having branches located in the recesses on opposite sides of an arm, said pistons each extending across the chamber, concentric grooves formed in the edge of the rim, and grooves extending radially along the edges of said pistons.

809,638. **HOPPER-BOTTOM CAR.** JOHN S. STEVENSON, Detroit, Mich. Filed Apr. 1, 1905. Serial No. 253,323.



Claim.—1. In a hopper-bottom car, the combination with plate-girder side walls, a center sill, a central cross-ridge arranged between the plate-girder sides and above the plane of the center sill and a cross-beam carried by the plate-girder sides in a plane beneath the center sill, for supporting said center sill; substantially as described.

2. In a hopper-bottom car, the combination with hoppers, of a pair of doors closing the openings thereof, a beam having a channel of varying depths, the central part being the deepest, said beam being riveted to the lower edges of said doors, a cap-plate fastened to said beam at the point where the channel is deepest, and a door-operating mechanism connected to said beam between the doors; substantially as described.

3. The combination with a pair of hopper-doors, of a pressed-steel channel-shaped beam riveted to the lower edges thereof, a channel in said beam being of varying depths, the central part being the deepest, a cap-plate between the doors, and a spacer interposed between the cap-plate and the channeled portion of said beam; substantially as described.

4. The combination with a hopper-door, of a channeled beam riveted thereto, a cap-plate riveted to the beam, a pipe in the channel of said beam and in line with said cap-plate, a screw-eye having nuts impinging against the outer faces of said channel and said cap-plate, and a door-operating mechanism connected to said screw-eye; substantially as described.

5. The combination with a hopper-door, of a link pivotally connected thereto, rollers carried by said link, a fixed abutment with which the link coöperates when the door is closed, and guides for said rollers; substantially as described.

6. The combination with hopper-doors, of links pivotally connected thereto, rollers on the inner ends of said links, abutment-blocks against which the links rest when the doors are closed, beams 8 to which said abutment-blocks are riveted, and guides 9 riveted to the ends of said beams, said guides coöperating with said rollers; substantially as described.

7. The combination with center sills, of a cross-beam arranged thereunder, a transverse cross-ridge arranged above the center sills, hopper-doors hinged to the legs of said cross-ridge, longitudinally-disposed beams riveted to the under side of the cross-beam, abutment-blocks and guides on said last-mentioned beams, and links pivotally connected to the hopper-doors and coöperating with said abutment-blocks and guides; substantially as described.

8. The combination with a hopper-door, of a link pivotally connected thereto at one end, the opposite end of said link carrying rollers, and guides for said rollers, which guides have an oblique portion approximately parallel to the plane of the doors in their closed position; substantially as described.

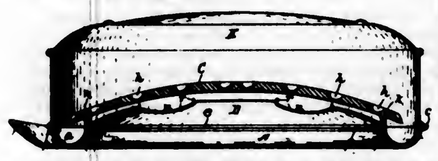
9. The combination with a hopper-door, of links pivotally connected thereto at one end, said links carrying rollers at their opposite ends, and a guide for said rollers, said guide having substantially vertical portions at its upper and lower extremities, and an intermediate obliquely-disposed portion; substantially as described.

10. The combination with a hopper-door, of an operating mechanism therefor comprising a rock-arm 14, links 15 and 17, rollers 16 at the pivotal connection between said links, channeled members 9 forming guides for said rollers, and an abutment-block; substantially as described.

11. The combination with a hopper-door, of a link pivotally connected thereto at one end, a guide for the opposite end of said link, another link pivotally connected to the guided end of said first-mentioned link, a rock-arm connected to said other link, whereby

when the door is in a closed position the rock-arm occupies a position of dead-center, and an abutment-block for supporting the guided end of said first-mentioned link when the door is closed; substantially as described.

809,639. **BROILER.** JOHN M. STORER, Cleveland, Ohio, assignor to the Prince Meikos Oil Stove Company, Cincinnati, Ohio. Filed June 13, 1905. Serial No. 265,669.



Claim.—1. A broiler consisting of a metal ring and a grid mounted upon the ring, and a sheet-metal dome held by the ring beneath the grid, the dome and the grid being crowning with space between.

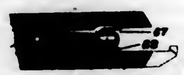
2. A broiler comprising a metal ring and a grid mounted thereon, and a sheet-metal dome upon the ring beneath the grid, the dome having slots with peripheral upwardly-projecting lips, the grid and the dome having a common seat upon the ring.

3. A broiler consisting of a ring or body having a flange and a horizontal circular ledge adjacent to the flange, and a grid upon the ring having a downwardly-projecting circular flange resting upon said ledge, and a sheet-metal dome having a peripheral flange adapted to rest upon said ledge between the flanges of the ring and the grid.

4. A broiler consisting of a ring or body having an upwardly-projecting circular flange *e* and a horizontal circular ledge at the base of the flange on its convex side, and a grid having a downwardly-projecting circular flange *k* adapted to rest upon the ledge, and a sheet-metal dome having a peripheral downwardly-turned flange adapted to rest upon said ledge between said opposing flanges *e k*, the opposing faces of said flanges *e k* and the flange of the dome all having an equal and similar slant.

5. A broiler consisting of a ring or body having an upwardly-projecting circular flange *e* and a horizontal circular ledge at the base of the flange on its convex side, and a grid having a downwardly-projecting circular flange *k* adapted to rest upon the ledge, and a sheet-metal dome having a peripheral downwardly-turned flange adapted to rest upon said ledge between said opposing flanges *e k*, the lower edge of the flange *k* in contact with the ledge being formed with a series of openings.

809,640. **GUN.** AUDLEY H. STOW, Hunter, W. Va. Filed Aug. 11, 1905. Serial No. 268,122.



Claim.—1. In an automatic gun, the combination of the hammer and means for cocking the same automatically, a sear, and a controlling-piece with which the hammer engages, to determine the hammer action.

2. In an automatic gun, the combination of the hammer, means for cocking the same automatically, a sear, and movable controlling-piece with which the hammer engages, to control the hammer action.

3. In an automatic gun, the combination of the hammer, means for cocking the same, a star, and a controlling-pin having cross-sections of different form, each cross-section of the pin controlling the hammer action according to a predetermined system.

4. In an automatic gun, the hammer, means for cocking the same automatically, a trigger-sear, a trigger-sear trip, and a movable controlling-piece having a series of bearing-surfaces, each bearing-surface controlling the hammer to operate in a predetermined manner, all combined.

5. In an automatic gun, the combination of the hammer, means for cocking the same, a trigger-sear, a trigger-sear trip, and a movable controlling-pin having cross-sectional areas of different dimensions, and engaging the trigger-sear trip to determine the hammer action.

6. In an automatic gun, the hammer and means for cocking the same, a controlling-pin extending through the frame and movable in direction of its length, and means for holding the said pin in different positions, thereby controlling the hammer movement.

7. In an automatic gun, the hammer and means for cocking the same, the movable controlling-pin extending through the frame and varying in cross-section, a pawl on the hammer which pawl engages the sections of said pin to govern the hammer action according to the position of the controlling-pin, and means for holding the controlling-pin in adjusted position, all combined.

8. In a magazine-gun, a magazine, a vertically-movable carrier, a carrier-lever connected to said carrier, two pivots supporting said lever on variable fulcrums, and a spring acting to raise or lower said carrier according to the position of the bearing-fulcrum.

9. In a magazine-gun, the carrier, a carrier-lever pivotally connected thereto, a plurality of fulcrums on one or the other of which the carrier is supported, and a spring operating to both raise and lower the carrier, all combined.

10. In a magazine-gun, the combination of a carrier, a lever pivotally connected thereto, two pivot-pins projecting from the carrier-lever, a frame having two slots in which said pivot-pins may play, and a spring connected to the carrier-lever between said pins.

11. In a magazine-gun, the combination of a carrier, carrier-lever pivotally connected thereto, two pivot-pins projecting from said lever, and a spring connected to the lever between said pins, and slots in the frame in which said pins play, one of said slots having a shoulder on which the pin rests when in elevated position.

12. In a magazine-gun, the combination of a carrier, a carrier-lever pivotally connected thereto and supported on one or the other of two fulcrums, a spring connected to said lever between the fulcrums, the breech-bolt and a lever connected thereto; and a carrier-lever catch connected to said breech-bolt lever.

13. In a magazine-gun, a longitudinally-moving breech-bolt, a return-lever pivotally connected thereto, a vertically-moving cartridge-carrier and a carrier-lever pivotally connected thereto, variable fulcrums supporting said carrier-lever, and means connected with the return-lever by which the carrier-lever may be shifted on its fulcrums.

14. In an automatic gun, the combination of a cylindrical longitudinally-reciprocating breech-bolt, a vertically-moving carrier having a chamber neatly fitting said bolt and the cartridge-body used in the gun, and means for reciprocating the carrier, so that the backward movement of the bolt permits the cartridge-shell to recoil into the carrier at the instant of firing.

15. In an automatic gun, a vertically-movable cartridge-carrier having a cylindrical bore which receives the cartridge, a longitudinally-reciprocating breech-bolt which fits said bore, and means for closing the breech-bolt through the chamber in the carrier, and means for lifting the carrier so that its chamber is in line with the breech-bolt.

16. In a magazine-gun, the combination of a vertically-reciprocating carrier, the trigger, and a carrier-catch connected to and operated by the trigger.

17. In a magazine-gun, the combination of a vertically-reciprocating cartridge-carrier, a trigger, and a carrier-catch pivoted in the frame and connected to the trigger.

18. In a magazine-gun, the combination of a reciprocating bolt, a firing-pin carried thereby, a spring-actuated firing-pin catch in the breech-bolt having an inclined surface, and the hammer engaging said incline to release the firing-pin before striking it.

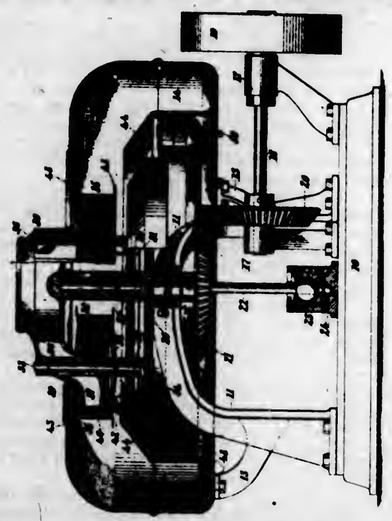
809,641. **VEHICLE-TIRE.** JAMES A. SWINEHART, Akron, Ohio. Filed Apr. 3, 1904. Serial No. 201,948.

Claim.—1. In vehicle-tires, a metallic rim having opposite inverted edges about its periphery, in combination with a solid continuous rubber tire in said rim provided with side ribs engaged beneath said edges, a binding material interposed between said rim and tire and cemented to both, and cross-wires extending transversely

through said tire and binding material and engaged at their ends beneath said incurved edges, substantially as described.

2. In a vehicle-tire, the combination of a metallic rim having inturned side edges with an elastic tire having side projections adapted to fit within said rim, and provided with metallic bars embedded diagonally of the tread and within said tire and adapted to engage and lock beneath said rim edges, and a binding material fastened to both said rim and tire adapted to fix and hold said bars in their locking position, substantially as described.

809,642. **CENTRIFUGAL MACHINE FOR SCREENING PULP.** CHARLES W. THOMAS, Nutley, N. J., assignor of one-half to Charles Smith, Belleville, N. J. Filed Apr. 8, 1904. Serial No. 202,208.



Claim.—1. In a machine of the character described, a series of vertical cylindrical screen vessels having perforated side walls, means for revolving said vessels around a central vertical axis, means for rotating said vessels on their own independent axes in a direction reversely to that of their revolving motion, and means for delivering the material to be screened to said vessels and directly against the perforated side walls of same and in a fixed direction with relation to said vessels so that as said material is thus delivered the said vessels present new surfaces to receive the same and the material within the vessels is thrown, by the main centrifugal action, to that side thereof which has just passed from said delivery means, combined with means for receiving the material which passes through said perforated walls; substantially as set forth.

2. In a machine of the character described, the series of discharge-spouts leading from a source of supply of the material to be screened, and a series of vertical cylindrical screen vessels having perforated side walls and openings in their upper and lower ends, said spouts passing directly into said vessels and into approximately near relation to the side walls of same and having their discharge ends pointed to said perforated side walls so as to deliver the material directly against the same, combined with means for revolving said vessels around a central vertical axis, means for rotating said spouts to follow said vessels, means for rotating said vessels on their own independent axes so that they may present new surfaces to said discharge-spouts, and means for receiving the material which passes through said perforated side walls; substantially as set forth.

3. In a machine of the character described, a vertical rotary shaft 22, a horizontal frame 29 to be rotated thereby, a series of gear-wheels 34 and vertical spindles 33 carried by said frame, a central stationary gear-wheel 26, and the series of intermediate pinion-wheels 46 connecting said gear-wheels 34 with said gear-wheel 26, combined with the screen vessels secured to said spindles 33 and having perforated side walls, means for supplying said vessels with the material to be screened, and means for imparting motion to said shaft 22; substantially as set forth.

4. In a machine of the character described, a vertical rotary shaft 22, a horizontal frame 29 to be rotated thereby, a series of gear-wheels 34 and vertical spindles 33 carried by said frame, a central stationary gear-wheel 26, and the series of intermediate pinion-wheels 46 connecting said gear-wheels 34 with said gear-wheel 26, combined with the screen vessels secured to said spindles 33 and having perforated side walls, the rotary feed-hopper connected with said shaft and having the radial spouts to discharge into said vessels, and means for imparting motion to said shaft 22; substantially as set forth.

5. In a machine of the character described, a horizontal rotary frame 29, a series of gear-wheels 34 and vertical spindles 33 carried by said frame, a central stationary gear-wheel 26, and the series of intermediate pinion-wheels 46 connecting said gear-wheels 34 with said gear-wheel 26, combined with the screen vessels secured to said spindles 33 and having perforated side walls, means for supplying said vessels with the material to be screened, and means for imparting rotary motion to said frame; substantially as set forth.

6. In a machine of the character described, a horizontal rotary frame 29, a series of gear-wheels 34 and vertical spindles 33 carried by said frame, a central stationary gear-wheel 26, and the series of intermediate pinion-wheels 46 connecting said gear-wheels 34 with said gear-wheel 26, combined with the screen vessels secured to said spindles 33 and having perforated side walls, means for supplying said vessels with the material to be screened, and means for imparting rotary motion to said frame, said means for supplying said vessels comprising a rotary feed-hopper having radial discharge-spouts leading directly into said vessels and terminating at one side of the center thereof in approximately near relation to the perforated walls of said vessels; substantially as set forth.

7. In a machine of the character described, the series of discharge-spouts leading from a source of supply of the material to be screened, a series of vertical cylindrical screen vessels having perforated side walls and each receiving the discharge from one of said spouts, means for revolving said vessels around a central vertical axis, means for rotating said spouts to follow said vessels, and means for rotating said vessels on their own independent axes in a direction reversely to that of their revolving motion, said spouts passing directly into said vessels and into approximately near relation to the side walls of same and having their discharge ends pointed to said perforated side walls so as to deliver the material directly against the same, combined with means for receiving the material which passes through said perforated walls; substantially as set forth.

8. In a machine of the character described, the series of spouts leading from a source of supply of the material to be screened, and a series of vertical cylindrical screen vessels having perforated side walls and each receiving the discharge from one of said spouts, said spouts being arranged to deliver the material directly against said perforated side walls, combined with means for revolving said vessels around a central vertical axis, means for rotating said spouts to follow said vessels, means for rotating said vessels on their own independent axes in a direction reversely to that of their revolving motion, means for receiving the material which passes through said perforated side walls, and means for receiving the material which fails to pass through said walls; substantially as set forth.

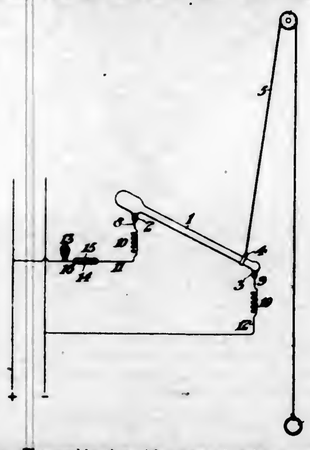
9. In a machine of the character described, a rotary frame 29, a series of gear-wheels 34 and spindles 33 carried by said frame, a central stationary gear-wheel 26, and the series of intermediate pinion-wheels 46 connecting said gear-wheels 34 with said gear-wheel 26, combined with the screen vessels secured to said spindles 33 and having perforated side walls, means for supplying said vessels with the material to be screened, and means for imparting rotary motion to said frame, substantially as set forth.

10. In a centrifugal pulp-screen, a central shaft, a series of individual screens mounted upon and revolving with said shaft, and means for revolving each of the series of individual screens upon its own axis, said means consisting of a stationary gear concentric with the central shaft, said stationary gear being operatively connected to the shafts of the individual screens by idler-gears located between the stationary gear and driving-gears on the individual shafts; substantially as described.

11. In a centrifugal machine for screening paper-pulp and the like, a vertical cylindrical screen vessel having an opening in its lower end and having perforated side walls, means for revolving said vessel around an axis exterior thereto, means for rotating said vessel on its own independent axis, and means for delivering the material to be screened to said vessel and directly against the vertical perforated side wall of same and in a fixed direction with relation to said vessel, whereby said vessel may constantly present new surfaces to receive said material, the perforations in said side walls being adapted to permit the good pulp only to pass through them, while the slivers and tailings escape through the lower end of said vessel; substantially as set forth.

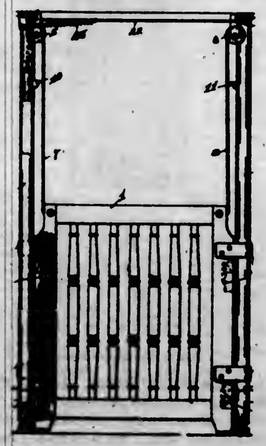
12. In a centrifugal machine for screening paper-pulp and the like, a vertical cylindrical screen vessel having an opening in its lower end and having perforated side walls, means for revolving said vessel around an axis exterior thereto, means for rotating said vessel on its own independent axis in a direction reversely to that of its revolving motion, and means for delivering the material to be screened to said vessel and directly against the vertical perforated side wall of same and in a fixed direction with relation to said vessel, whereby said vessel may constantly present new surfaces to receive said material, the perforations in said side walls being adapted to permit the good pulp only to pass through them, while the slivers and tailings escape through the opening in the lower end of said vessel; substantially as set forth.

809,643. **MEANS FOR CONTROLLING MERCURY-VAPOR ELECTRIC LAMPS.** PERCY H. THOMAS, East Orange, N. J., assignor to Cooper Hewitt Electric Company, New York, N. Y., a Corporation of New York. Filed Apr. 23, 1904. Serial No. 204,047.



Claim.—The combination with a vapor electric apparatus which is adapted to be started by rupturing a conducting film or bridge between the electrodes, of a carbon filament in series with apparatus and a ballast also in series with the apparatus, said ballast having a positive temperature coefficient.

809,644. **ELEVATOR-GATE.** GEORGE D. THOMPSON, Arlington Heights, Ohio. Filed Aug. 7, 1905. Serial No. 273,152.



Claim.—1. In combination with an elevator-car, a vertically-sliding counterbalanced gate, having top and bottom latches, a rotatable member having top and bottom catches in different vertical lines, and means actuated by the car to rotate said member whereby one of the catches is moved out and the other into position for engagement with its coöperating latch on the gate, substantially as described.

2. In combination with an elevator-car, a vertically-sliding counterbalanced gate, having top and bottom latches, a rotatable member having corresponding top and bottom catches projected in different vertical lines, means for holding said rod yieldingly in normal position with the bottom catch and latch in engagement, and means actuated by the car for rotating said member to release the bottom catch and to throw the top catch into position for engaging the top catch when the gate is raised, substantially as described.

3. In combination with an elevator-car, a vertically-sliding gate, having top and bottom latches, a rotatable tube at the side of the gateway, a counterbalance for the gate sliding in said tube, a top and bottom catch radially projected from the tube in different vertical lines, means for holding said tube in the given position yieldingly, and means actuated by the car for turning said tube to release one catch and latch and engage another, substantially as described.

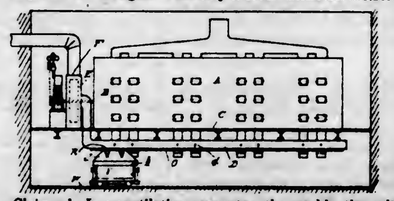
4. In combination with an elevator-car, a vertically-sliding gate having top and bottom latches on each side, a rotatable tube on each side of the gateway, counterbalances for said gate sliding in said tubes, top and bottom catches on each tube radially projected in different vertical lines, means connecting said tubes whereby they rotate in unison, means for holding said tubes yieldingly in a given position, and means actuated by the car for rotating said tubes whereby one set of catches and latches are released and the other set of catches thrown into position to engage their coöperating latches, substantially as described.

5. In combination with an elevator-car, a vertically-sliding gate having latches, a rotatable member having catches in different vertical lines, and means actuated by the car to rotate said member whereby the catches are moved into and out of position, substantially as described.

6. In combination with an elevator-car, a vertically-sliding gate having latches, rotatable members having catches in different vertical lines, vertical guide connections between said members and the gate, and means actuated by the car to operate said catches, substantially as described.

7. In combination with an elevator-car, vertical tubes rotatably mounted in the sides of the gateway, a sliding gate between said tubes having counterbalances sliding within said tubes, said tubes having catches extending radially in different vertical lines, coöperating latches on the gate, and vertical guide connections projected from the gate and engaging around the tubes, substantially as described.

809,645. **VENTILATING APPARATUS.** CHARLES H. TREAT, Detroit, Mich., assignor to American Blower Company, Detroit, Mich., a Corporation of Michigan. Filed July 5, 1904. Serial No. 215,209.



Claim.—1. In a ventilating apparatus, the combination with a member having discharge-openings longitudinally thereof, of a draft-conduit having a series of separated inlet-openings extending longitudinally thereof in line with said discharge-openings, a series of dampers controlling the inlet-openings, means for independently operating the dampers, a traveling receptacle movable in operative relation with any one of said conduit-openings and its corresponding discharge-opening, and a hood for the receptacle having openings, one for filling the receptacle from the chute and the other for communicating with the inlet-openings.

2. In a ventilating apparatus, the combination with a draft-conduit provided with a damper-controlled inlet-opening, of a chute adjoining the conduit, and a movable hood adapted to fit over a receptacle to be filled from the chute, the hood having an opening to

register with the chute and another affording communication with the conduit through said inlet.

3. In a ventilating apparatus, the combination with a draft-conduit provided with an inlet-opening, of a chute adjoining the conduit, an open-bottom hood having an auxiliary opening in its side registering with the end of said chute to admit the chute contents and an open top registering with the inlet-opening in the conduit, and a receptacle arranged below the open bottom of the hood.

4. In a ventilating apparatus, the combination with a member having discharge-openings, of an air-conduit provided with a corresponding series of inlet-openings, means for inducing a draft through said conduit, and a hood mounted for travel longitudinally of the discharge-openings and conduit and having an exit-opening adapted to be brought in registration with any of the inlets in said conduit.

5. In a ventilating apparatus, the combination of a member having discharge-openings, a substantially horizontal draft-conduit having a series of damper-controlled inlet-openings extending lengthwise thereof, and a hood mounted upon the conduit for longitudinal travel and having an exit-opening adapted to register with any of the conduit-inlets.

6. In a ventilating apparatus, the combination with a series of ovens or retorts, of a series of chutes arranged to receive the retort contents, a draft-conduit having a plurality of damper-controlled inlet-openings corresponding in number to and arranged in line with the chutes, and a traveling hood adapted to be moved into operative relation with any one of the chutes and the corresponding conduit-inlet.

7. In a ventilating apparatus, the combination with a horizontally-extending draft-conduit having a series of damper-controlled inlets formed in its lower wall, of a discharging member having a series of outlets, a receptacle arranged beneath the discharging member and conduit for relative longitudinal travel, and a hood for said receptacle mounted for travel longitudinally of the latter and the conduit, the said hood having openings, one for filling the receptacle from the chute and the other for communicating with the inlets.

8. In a ventilating apparatus, the combination with a discharging member having a series of discharge-openings, of a draft-conduit having a series of inlets corresponding in number to and arranged in line with said discharge-openings, and a traveling hood adapted to fit over a receptacle to be filled from the discharging member, the hood having an opening to register with the discharge-opening and an opening affording communication with the conduit through said inlets.

9. In a ventilating apparatus, the combination with a series of ovens or retorts, of a series of chutes arranged to receive the retort contents, a draft-conduit having a plurality of inlet-openings corresponding in number to and arranged in line with the chutes, and a traveling hood adapted to be moved into operative relation with any one of the chutes and the corresponding conduit-inlet.

10. In a ventilating apparatus, the combination with a member having discharge-openings, of an air-conduit provided with a corresponding series of inlet-openings, means for inducing a draft through said conduit, a hood mounted for travel longitudinally of the discharge-openings and conduit and having an exit-opening adapted to be brought in registration with any of the inlets in said conduit, and a traveling receptacle movable in operative relation with any one of said conduit-openings and the corresponding discharge-opening.

809,646. COMBINED PEN-RACK AND INKSTAND-HOLDER. LEDA TIFFENY, New York, N. Y. Filed Jan. 16, 1905. Serial No. 241,202.

Claim.—1. As an article of manufacture, an inkstand-holder composed of a shell having a ledge, said ledge being provided with means for holding an inkstand, and also provided with means for supporting the shell and maintaining the ledge substantially horizontal.

2. As an article of manufacture, an inkstand-holder composed of a shell having a ledge, the latter being provided with means for holding an inkstand, and said ledge having mechanically combined therewith a leg for supporting the same substantially horizontal.

3. An inkstand-holder composed of a shell having a ledge, the latter having secured thereto a plurality of supporting-legs, and the shell having the bottom of its body portion shaped or formed to produce another supporting-leg, the said legs being disposed in triangular relation, so as to afford a substantial support for the shell.

4. An inkstand-holder composed of a shell having a ledge, the latter having means secured thereto for holding an inkstand, and the body of the said shell being carved, or otherwise ornamented, so as to produce a support for a penholder.

5. The article of manufacture described, composed of a shell having means on its bottom for supporting it, and having its body portion carved and ornamented so as to produce one or more supports for a penholder.

6. An inkstand-holder comprising a body portion having a laterally-extended ledge, and means for supporting said holder comprising an integral extension thereof and one or more legs detachably secured thereto, whereby the holder may be supported with its bottom free from the table, &c., and its ledge substantially horizontal, irrespective of the shape, form or configuration of said bottom.

7. An inkstand-holder comprising a body portion having an extended ledge and also having means for supporting the body portion free from the table, &c., a device for holding an inkstand supported by the ledge, and a clamping means for securing the supporting means and holding device to the ledge.

809,647. ELECTRIC CELL. KUHAIRO TSUKAMOTO, Tokyo, Japan. Filed Jan. 14, 1904. Serial No. 189,066.

Claim.—In an electric cell the combination of an outer casing having located therein a carbon tube containing graphite, manganese dioxid, potassium chlorid, potassium permanganate and ammonium chlorid, a fibrous substance bound around the carbon tube, and a mixture composed of ammonium chlorid, potassium chlorid, gypsum, mercuric sulfate, and dextrin located between the inner surface of the shell and the fibrous or blotting paper located around the carbon tube, substantially as and for the purpose specified.

809,648. FEED CONCENTRATOR. LEWIS R. TILLOTT, Angels Camp, Cal. Filed Feb. 6, 1904. Serial No. 192,269.

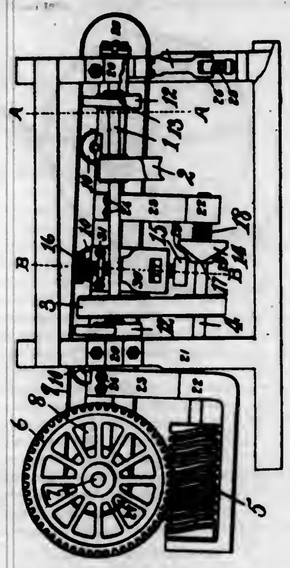
Claim.—1. In a concentrator, the combination of a shaft, means for revolving said shaft, a worm thereon, a frame, drums on said frame, an endless concentrating-belt around said drums, a worm-wheel meshing with said worm and operatively connected with one of said drums to revolve the same, and positive means independent of the connection with the worm-wheel for imparting a longitudinal reciprocation to said shaft, whereby is produced a comparatively rapid oscillation of the worm-wheel and a corresponding longitudinal reciprocation of the belt in addition to its slow advance, substantially as described.

2. In a concentrator, the combination of a shaft, means for revolving said shaft, a worm thereon, a frame, drums on said frame, an endless concentrating-belt around said drums, a worm-wheel meshing with said worm and operatively connected with one of said drums to revolve the same, and means for imparting a longitudinal reciprocation to said shaft, said means comprising a cam on said shaft, and a device engaging said cam, whereby is produced a comparatively rapid oscillation of the worm-wheel and a corresponding longitudinal reciprocation of the belt in addition to its slow advance, substantially as described.

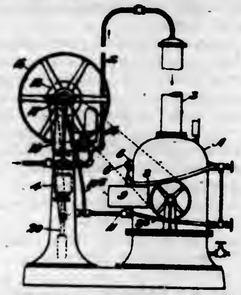
3. In a concentrator, the combination of a shaft, means for revolving said shaft, a worm thereon, a frame, drums on said frame, an endless concentrating-belt around said drums, a worm-wheel meshing with said worm and operatively connected with one of said drums to revolve the same, and means for imparting a longitudinal reciprocation to said shaft, said means comprising a conical cam on said shaft, a roller engaging said cam, and means for adjusting said roller to and from the axis of the cam, whereby is produced a comparatively rapid oscillation of the worm-wheel and a corresponding longitudinal reciprocation of the belt in addition to its slow advance, substantially as described.

4. In a concentrator, the combination of a shaft, means for revolving said shaft, a worm thereon, a frame, drums on said frame, an endless concentrating-belt around said drums, a worm-wheel meshing with said worm and operatively connected with one of said drums to revolve the same, and means for imparting a longitudinal reciprocation to said shaft, said means comprising a conical cam on said shaft having a flattened central surface, a roller engaging said cam, and means for adjusting said roller to and from the axis of the cam, whereby is produced a comparatively rapid oscillation of the worm-wheel and a corresponding longitudinal reciprocation of the belt in addition to its slow advance, substantially as described.

5. The combination of a frame, a shaft mounted therein, a worm wheel on said shaft, a worm engaging said worm-wheel, a shaft for the worm, bearings therefor secured to said frame, said shaft being slidable in said bearings, means for turning the shaft in said bearings and positive means independent of the connection with the worm-wheel for reciprocating the shaft therein, whereby, in addition to the slow rotary movement of the worm-wheel shaft a comparatively rapid oscillating movement is imparted thereto, substantially as described.

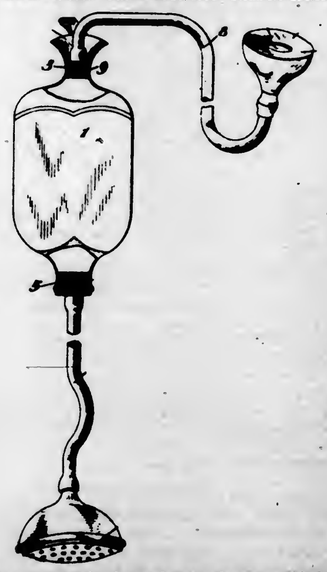


809,649. AUTOMATIC ATTACHMENT FOR CARBONATING APPARATUS. HENRY W. VAN DER VAART, San Francisco, Cal. Filed Apr. 11, 1905. Serial No. 254,996.



Claim.—A carbonating apparatus having in combination a fluid-chamber, a pump supplying said chamber, a lever fulcrumed between its ends, a weight adjustable on the lever at one side of its fulcrum-point, a chamber suspended from the lever at the opposite side of its fulcrum-point, pipes connecting the carbonating-chamber with opposite portions of the suspended chamber, a crank-shaft and connections by which the pump is driven, a pulley loose on said shaft and provided with a clutch member, a companion clutch member slidable on the shaft, a lever fulcrumed between its ends having one end engaging the slidable clutch member, a link connected to the opposite end of the last lever, a bell-crank lever having one arm connected to said link, and a link connecting the opposite arm of the bell-crank lever with an arm of the first lever.

809,650. COMBINED HOT-WATER BAG AND SYRINGE. MARGARET VAN TASSEL-BECK, Cleveland, Ohio, assignor of one-half to Elmer E. Bellamy, Cleveland, Ohio. Filed June 25, 1904. Serial No. 214,128.



Claim.—As a new article of manufacture, the convertible hot-water bag, syringe and spray herein described, comprising a hot-water bag, flexible tubes for attachment to opposite ends thereof and respectively provided with a connection for a faucet, and a discharge-head, whereby a circulation directly from the faucet through the bag and the discharge-head may be obtained, and the force of the head of

water from the faucet, as well as the weight of water in the bag utilized, and stoppers for substitution for the said flexible tubes, to close the openings at the ends of the bag and enable the latter to be used for the purpose of a hot-water bag.

809,651. PROCESS FOR PRODUCING MULTICOLORED PHOTOGRAPHIC PROOFS. SOLON VATHIS, Paris, France. Filed July 26, 1905. Serial No. 271,622.

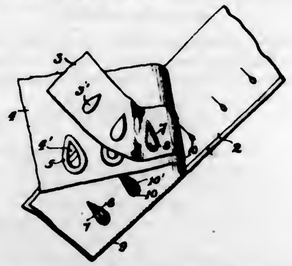
Claim.—1. A process for producing multicolored photographic proofs, consisting in exposing a sensitized surface, toning said surface, fixing the image thereon, and submitting said surface to the action of varying degrees of heat at the places where coloration is required at a minimum temperature of 55°, substantially as described.

2. A process for producing multicolored photographic proofs, consisting in exposing a sensitized surface, toning said surface in a solution of hydrochloric acid and chlorid of gold, fixing the image thereon, and submitting said surface to the action of varying degrees of heat at the places where coloration is required at a minimum temperature of 55°, substantially as described.

3 A process for producing multicolored photographic proofs, consisting in exposing a sensitized surface, toning said surface in a solution of hydrochloric acid and chlorid of gold, fixing the image thereon, and submitting said surface to the action of varying degrees of reflected heat at the places where coloration is required at a minimum temperature of 55°, substantially as described.

4. A process for producing multicolored photographic proofs, consisting in exposing a sensitized surface, toning said surface in a solution of hydrochloric acid and chlorid of gold, fixing the image thereon, submitting said surface to the action of varying degrees of heat at the places where coloration is required at a minimum temperature of 55°, and placing said proofs in water, substantially as described.

809,652. BUTTONHOLE. HENRY WALDEN, Philadelphia, Pa. Filed Nov. 1, 1904. Serial No. 231,009.



Claim.—1. A buttonhole-stay comprising a metallic stay having a hole therein, and a leather stay having a hole therein, said leather stay having a flap folded over said metallic stay, substantially as specified.

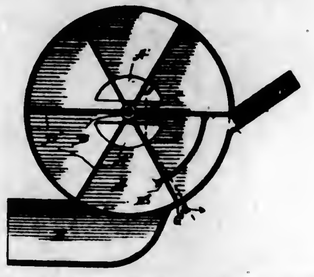
2. In a buttonhole, a stay having a hole therein, a leather member having a hole therein registering with the hole in said stay, means for securing said stay to said member, and a second leather member secured to said first member, said second member having a hole therein which registers with and partially covers the holes in said stay and first member, substantially as specified.

3. In a buttonhole, a sheet-metal stay having a hole therein, a lining and an interior reinforcing-piece having holes therein registering with the holes in said stay, means for fastening said elements together about said holes, and an outer piece joined to said lining and having a hole therein registering with the hole formed by joining said elements, substantially as specified.

809,653. APPARATUS FOR VENTILATING MINES. MICHAEL J. WARD, Rhinesville, Pa. Filed Apr. 11, 1904. Serial No. 202,627.

Claim.—1. An apparatus for ventilating mines comprising a fan and casing therefor, with openings in the sides thereof, curved flanges upon the opposite walls of said casing and of sufficient length to form closed compartments by the rotating blades of the fan, a nozzle adapted to direct compressed air into the space intermediate said flanges and the circumferential wall of the casing, the wall of the casing opposite the lower ends of said flanges being apertured, and a pipe leading away from the casing, as set forth.

2. An apparatus for ventilating mines comprising a casing, a shaft journaled in said casing, fan-blades upon said shaft, said blades having oppositely-disposed recesses cut in from the edges thereof, curved flanges projecting from the inner faces of the side walls of the casing over which said recesses pass as the blades rotate, a nozzle extending into a tubular projection of the casing and having an exit end adjacent to the upper ends of said flanges, the circumferential wall of the casing having an exit-aperture opposite the lower ends of said flanges, and a pipe leading from the casing, as set forth.



3. A ventilating apparatus for mines comprising a casing having a tubular extension upon the circumference thereof and an exit passage-way, the opposite walls of the casing having apertures for the inlet of fresh air, a shaft journaled in said casing, blades fixed to said shaft and having their opposite edges scalloped adjacent to their inner ends, each blade having elongated recesses cut in from the opposite edges thereof, intermediate the outer marginal edges of said scallops and the free ends of the blades, curved flanges oppositely disposed and fastened to the side walls of the casing and over which said recesses are adapted to pass, a nozzle positioned in said tubular extension of the casing, having an exit end opposite the upper ends of said flanges, the circumference of said casing having an exit-aperture opposite the lower ends of said flanges, as set forth.

809,654. EXHAUST-MUFFLER. LOUIS T. WEISS, Brooklyn, N. Y. Filed Aug. 18, 1905. Serial No. 274,742.

Claim.—1. An exhaust-muffler, having an expansion-chamber which receives the exhaust from the engine, said chamber having an outlet for the exhaust, and automatic means controlling said outlet and opening and closing the latter alternately.

2. An exhaust-muffler, having an expansion-chamber, which receives the exhaust from the engine and which has an outlet for the exhaust, and an automatic, moving valve which closes and opens said outlet alternately, said openings and closings corresponding to the times of the exhaust of the engine.

3. An exhaust-muffler, having a chamber open to the exhaust, said chamber having also an outlet for the exhaust, and a rotating, ported valve controlling the said outlet.

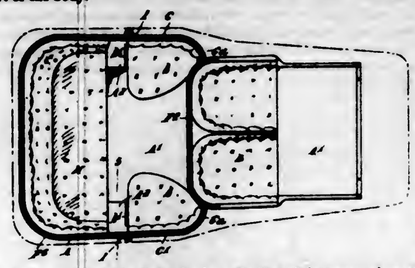
4. An exhaust-muffler, having a chamber open to the exhaust, said chamber having also an outlet for the exhaust, a moving valve controlling said outlet, and a spring which holds said valve yieldingly up to its seat, said spring being so disposed as to yieldingly oppose the pressure of the exhaust-gases.

5. An exhaust-muffler, having an expansion-chamber open to the exhaust, and said chamber having also an outlet-port 3 for the exhaust, a rotating arbor 6, a valve 4 on said arbor and provided with a port 5 adapted to be put into coincidence with the port 3 by rotation of the valve, and spring 10, which holds said valve yieldingly up to its seat.

809,655. AUTOMOBILE-BODY. ALLIE R. WELCH and FRED S. WELCH, Pontiac, Mich. Filed May 29, 1905. Serial No. 262,781.

Claim.—1. An inclosed carriage-body divisible along the line of the upper edges of the sides of the seats and back of the front and rear seat, substantially as shown and for the purpose described.

2. A carriage-body divisible along the line of the upper edges of the sides of the seats and back of the rear seat, and bolts extending from the top of the upper portion of the body and engaging the lower part of the body.



3. A carriage-body divisible along the line of the upper edges of the sides of the seats and back of the rear seat, and bolts extending from the top of the upper portion of the body within the wall thereof and engaging the lower part of the body.

4. A carriage-body provided with a rear inclosed portion extending laterally beyond the front portion, and a door hinged to the rear portion and bending inward to meet the front portion.

5. A carriage-body provided with a rear inclosed portion extending laterally beyond the front portion, and a door hinged to the rear portion and bending inward to meet the front portion, said door being provided with an inwardly-extending seat secured thereto.

6. In a carriage-body, the combination of a door having an inwardly-extending seat secured thereto, and means for securing said door when in its closed position, independent of the seat.

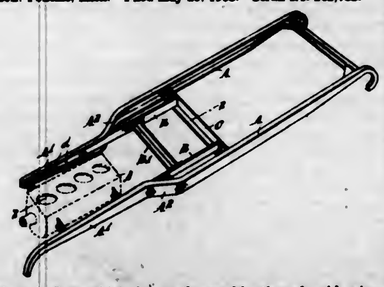
7. In a carriage-body, the combination of a door having an inwardly-extending seat secured thereto, a ledge upon said body, said door being provided with a portion adapted to pass over and rest upon said ledge when the door is closed.

8. In a carriage-body, the combination of a door having an inwardly-extending seat thereto, a ledge upon said body, said door being provided with a portion adapted to pass over and rest upon said ledge when the door is closed, and interlocking projections I.

9. In a carriage-body, the combination of a door having an inwardly-projecting seat, ledges A^1, A^2, said door being provided with portions adapted to pass over and rest upon said ledges, interlocking projections I, and means for securing said door in its closed position.

10. A carriage-body provided with a rear inclosed portion extending laterally beyond the front portion, a door having an inwardly-extending seat hinged to the rear portion and adapted to close against the forward portion.

809,656. AUTOMOBILE-FRAME. ALLIE R. WELCH and FRED S. WELCH, Pontiac, Mich. Filed May 29, 1905. Serial No. 262,782.



Claim.—1. In a vehicle-frame, the combination of a side piece bent inward for a portion of its length and a strip rigidly secured to the bent-in portion of said side piece, extending beyond said bent-in portion at a distance from said side piece and rigidly secured toward its end to said side piece.

2. In a vehicle-frame, the combination of two side pieces bent inward for adjacent portions of their lengths, a strip rigidly secured to the bent-in portion of each of said side pieces extending beyond said bent-in portion at a distance from said pieces and means for rigidly securing said strips together and to the side pieces at points remote from said bent-in portions of the side pieces.

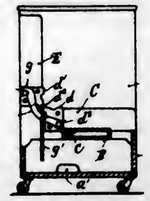
3. In a vehicle-frame, the combination of two side pieces bent inward for adjacent portions of their lengths, a strip rigidly secured to the bent-in portion of each of said side pieces extending beyond said bent-in portion at a distance from said pieces and means for rigidly securing said strips together and to the side pieces at points remote from said bent-in portions of the side pieces, and a brace extending between said bent-in portions of the side pieces.

4. In a vehicle-frame, the combination of two side pieces bent inward for adjacent portions of their lengths, a strip rigidly secured to the bent-in portion of each of said side pieces extending beyond said bent-in portion at a distance from said pieces and means for securing said strips rigidly together and to the side pieces at points remote from said bent-in portions of the side pieces, and a brace extending between said strips.

5. In a vehicle-frame, the combination of two side pieces bent inward for adjacent portions of their lengths, a strip secured to the bent-in portion of each of said side pieces, extending beyond said bent-in portion at a distance from said pieces, means for securing said strips rigidly together and to the side pieces at points remote from said bent-in portions of the side pieces, and a crank-case secured to said bent-in portions of the side frames, and serving as a brace therefor.

6. In a vehicle-frame, the combination of a side piece U-shaped in cross-section bent inward for a portion of its length and a strip rigidly secured to the bent-in portion of said side piece within the hollow of the U-shaped cross-section with its edges abutting against the flanges, said strip extending beyond said bent-in portion at a distance from said side piece and rigidly secured toward its end to said side piece.

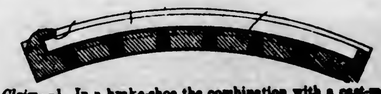
809,657. SOFA-BED. GEORGE N. WERNEL, Cincinnati, Ohio. Filed Aug. 14, 1905. Serial No. 274,089.



Claim.—1. In a sofa-bed the combination of a seat, a back, a hinge coupling the seat and the back, a latch pivoted to the seat and having a hook adapted to removably engage a projection upon the back, and a dependent rod pivoted to the latch for disengaging the latch from the projection on the back when the seat is raised.

2. In a sofa-bed the combination of a base, brackets secured to the base, a seat reciprocating in the brackets, a back, a hinge coupling the back and the seat, a latch pivoted to the member of the hinge attached to the seat and having a hook at the other end, a stud projecting from the member of the latch attached to the back and adapted to engage the hook, a block secured to the base, and a dependent rod pivoted to the latch and adapted to engage the block when the seat is brought forward and raised.

809,658. BRAKE-SHOE. HORACE L. WINSLOW, Chicago, Ill. Filed Feb. 17, 1905. Serial No. 245,909.



Claim.—1. In a brake-shoe the combination with a cast-metal body, of a strengthening-plate located at the back of said body, and a plurality of staggered projections extending from the longitudinal edges of said plate and embedded in said body.

2. In a brake-shoe the combination with a cast-metal body, of a strengthening-plate comprising parallel sections located at the back of said body, and projections extending from the longitudinal edges of the sections of said plate and embedded in said body.

3. In a brake-shoe the combination with a cast-metal body, of a strengthening-plate located at the back of said body, projections extending from said plate and embedded in said body, inserts in the wearing-surface of the shoe, and means for securing said inserts to said back plate.

4. In a brake-shoe the combination with a cast-metal body, of a strengthening-plate located at the back of said body, projections extending from the longitudinal edges of said plate and embedded in said body, and inserts in the wearing-surface of the shoe secured to said projections.

5. In a brake-shoe the combination with a cast-metal body, of a strengthening-plate located at the back of said body, projections extending from the longitudinal edges of said plate, and embedded in said body, said projections forming a dovetailed channel, inserts in the wearing-surface of the shoe, and dovetailed lugs on said inserts engaged with the channels between said projections.

6. In a brake-shoe the combination with a cast-metal body, of a strengthening-plate comprising parallel sections located at the back of said body, projections extending from the longitudinal edges of the parallel sections of said plate and embedded in said body, the projections on each section forming a dovetailed channel, inserts in the wearing-surface of the shoe, and dovetailed lugs on said inserts received within said channels.

7. In a brake-shoe the combination with a cast-metal body, of a strengthening back plate formed in two parts arranged end to end, outwardly-projecting ears formed integrally with the inner ends of the two parts of said plate, said ears having holes therethrough for the passage of a fastening-key.

8. In a brake-shoe the combination with a cast-metal body, of a strengthening back plate formed in two parts arranged end to end, outwardly-projecting ears formed integrally with the inner ends of the two parts of said plate, said ears having holes therethrough for the passage of a fastening-key, and strengthening-flanges formed integrally with the outer ends of said ears.

9. In a brake-shoe the combination with a cast-metal body and key-lug formed integrally therewith, of a strengthening back plate formed in two parts located at each side of said lug, outwardly-projecting ears formed integrally with the inner ends of the two parts of said plate, said ears having holes therethrough registering with the keyhole in said lug.

10. In a brake-shoe the combination with a cast-metal body, of a strengthening back plate formed in two parts arranged end to end, outwardly-projecting ears formed integrally with the inner ends of the two parts of said plate, said ears having holes therethrough for the passage of a fastening-key, each part of said plate comprising parallel sections and projections extending from the longitudinal edges of the parallel sections of said plate and embedded in said body.

11. In a brake-shoe the combination with a cast-metal body, of a strengthening back plate formed in two parts located end to end, inserts in the wearing-surface of the shoe and means for securing said inserts to said back plate.

12. In a brake-shoe the combination with a cast-metal body, of a strengthening back plate formed in two parts located end to end, outwardly-projecting ears formed integrally with the inner ends of the two parts of said plate, said ears having holes therethrough for the passage of a fastening-key, each part of said plate comprising parallel sections, projections extending from the longitudinal edges of each section of the two parts of said plate and embedded in said body, inserts in the wearing-surface of the shoe, and means for securing said inserts to said projections.

13. In a brake-shoe the combination with a cast-metal body, of a strengthening-plate located at the back of said body, and inserts secured to said plate and forming portions of the wearing-surface of the shoe.

14. A brake-shoe comprising a back plate, a plurality of inserts carried by said plate, and a body cast around and locked to said inserts.

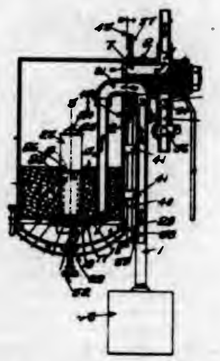
15. A brake-shoe comprising a back plate, depending lips on the back plate, inserts having a dovetailed connection with said lips, and a body having a dovetailed connection with said inserts.

16. A brake-shoe comprising a back plate, a body, an attaching-lug integral with the body and made in the shape of a hook, and a hook on the plate forming an inside lining for said lug.

17. A brake-shoe comprising a back plate, a body cast on the back plate, an attaching-hook on said back plate, and a lug cast integrally with said body engaging the outer surface of said hook to strengthen the same.

809,659. **PURIFIER FOR GAS.** BERNE C. WESTWORTH, Deer Isle, Me. Filed June 16, 1905. Serial No. 265,552.

Claim.—1. A purifier for gas comprising a filter-box, a rotary valve fast to said box and having an inlet-passage leading through said valve into said box and an outlet-passage leading from said box out through said valve, a valve-casing having a cylindrical chamber in which said valve is journaled, an inlet-passage through the valve-casing with which a feed-pipe and the inlet-passage in the valve are adapted to connect, an outlet-passage through the valve-casing with which the outlet-passage in the valve and a burner-tube are adapted to connect, means for rotating said valve and filter-box to close said inlet and outlet passages, and a drain-passage through said valve-casing to the outside air with which said gas-outlet passage in the valve connects when the valve and box are reversed to close the gas-passages.



2. A purifier for gas comprising a reversible filter-box, a valve-casing, a valve connected with said box and having a passage leading from the feed-pipe through the valve-casing and valve into said filter-box and a passage leading from said filter-box through the valve and casing into a house-supply pipe, means for reversing said box and valve, thereby closing said valve inlets and outlets, and a drain-passage through the valve-casing with which one of the passages in the valve connects when the valve and filter-box are reversed.

3. A purifier for gas having a rotatable filter-box, an opening in the bottom of the box, a cover for said opening, a valve connected with the upper part of said box and having a passage connecting therethrough with an inlet-pipe, a passage leading therethrough to an outlet-pipe, a diaphragm dividing the filter-box into two chambers, a pipe leading from said inlet-passage of the valve into the lower chamber, a pipe leading from said lower chamber and projecting up some distance into the upper chamber, perforations in the upper portion of said second tube, a filtering material in said upper chamber below said perforations, a thimble over the upper end of said second pipe and extending down into said filtering material, means for turning said filter-box and valve to reverse the ends of the box, and close the gas inlets and outlets of the valve, and an outlet-passage for drawing off the filtering material from the box when the box is in the said reversed position.

4. A purifier for gas having a filter-box, a valve connected with the upper part of said box and having a passage connecting therethrough with an inlet-pipe, a passage leading therethrough to an outlet-pipe, a diaphragm dividing the filter-box into two chambers, a pipe leading from said inlet-passage of the valve into the lower chamber, a pipe leading from said lower chamber and projecting up some distance into the upper chamber, perforations in the upper portion of said second tube, a filtering material in said upper chamber below said perforations, and a thimble over the upper end of said second pipe and extending down into said filtering material.

5. A purifier for gas having a filter-box, a valve connected with the upper part of said box and having a passage connecting therethrough with an inlet-pipe, a passage leading therethrough to an outlet-pipe, a diaphragm dividing the filter-box into two chambers, a pipe leading from said inlet-passage of the valve into the lower chamber, a pipe leading from said lower chamber and projecting up some distance into the upper chamber, perforations in the upper portion of said second tube, a filtering material in said upper chamber below said perforations, and a thimble over the upper end of said second pipe and extending down into said filtering material, said thimble being formed with teeth on its lower end.

6. A purifier for gas having a rotatable filter-box, an opening in the bottom of the box, a cover for said opening, a valve connected with the upper part of said box and having a passage connecting therethrough with an inlet-pipe, a passage leading therethrough to an outlet-pipe, a diaphragm dividing the filter-box into two chambers, a pipe leading from said inlet-passage of the valve into the lower chamber, a pipe leading from said lower chamber and projecting up some distance into the upper chamber, perforations in the upper portion of said second tube, a filtering material in said upper chamber, a tube of fabric inclosing the perforated portion of the pipe, and a thimble over the upper end of said pipe outside of said fabric tube and extending down into the filtering material.

7. A purifying apparatus for gas having a box divided by a diaphragm into an upper and lower chamber, an inlet-pipe for the impure gas leading into the lower chamber, an upright tube leading from the interior of the lower chamber up some distance into the upper chamber, perforations in the upper portion of the said tube, filtering material partially filling the upper chamber but not extending up to the said perforations in said tube, a thimble or hood on the upper end of said tube and extending down into said filtering material, and an outlet for the gas from the filter-box above the filtering material.

8. A purifying apparatus for gas having a box divided by a diaphragm into an upper and lower chamber, an inlet-pipe for the impure gas leading into the lower chamber, an upright tube leading from the interior of the lower chamber up some distance into the upper chamber, perforations in the upper portion of the said tube, filtering material partially filling the upper chamber but not extending up to the said perforations in said tube, a casing of filtering fabric surrounding the perforated portion of said tube, and a thimble or hood on the upper end outside of said fabric tube and extending down into the filtering material, and an outlet for the gas from the filter-box after it has passed through the filtering material.

9. A reversible filter-box for purifying gas having an opening in the lower end of the box, a cover for said opening, means for clamping said cover in a closed position with gas-tight joint, a diaphragm dividing the box into an upper and lower chamber, an inlet-tube for the impure gas leading into the lower chamber, a removable pipe having a screw-threaded connection with a socket in said diaphragm and extending up into the said upper chamber, an opening from the lower chamber into said pipe, ports in the upper portion of said pipe opening into the upper chamber, a filtering material in said upper chamber, but not reaching up to said ports, and a deflector on the upper end of said pipe extending down into said filtering material, means for inverting said box and closing the inlet and outlet for the gas, and an outlet-passage which connects with the portion of the box which becomes the lower end when the box is in the inverted position.

10. A rotary filter-box for purifying gas having an opening in the lower end of the box, a cover for said opening, a hinged clamp which holds said cover closed, means for turning said box into an inverted position, a slide-rod hinged at one end to the hinge edge of said clamp, and forked at its other end, and a notched plate with which said fork engages when the said rod is moved by the opening of said clamp.

809,660. **INTERCHANGEABLE LOCK AND CHAIN STITCH SEWING-MACHINE.** WILLIAM M. ASHERMAN, New Haven, Conn., assignor to The Edwin J. Teaf Company, New Haven, Conn., a Corporation of New Jersey. Filed May 2, 1904. Serial No. 206,883.

Claim.—1. In a sewing-machine, the combination with a reciprocating needle, a loop-taker, a forked loop-holder operative for receiving the needle-thread loop after it has been released by the loop-taker and holding the same in an open or distended condition across the path of the needle and thereafter releasing the loop subsequent to the passage thereinto of the needle, and means for actuating the loop-holder, of a guard coöperating with the said loop-holder when in loop-holding position for retaining the thread-loop thereon.

2. In a sewing-machine, the combination with a reciprocating needle, a loop-taker, a forked loop-holder operative for receiving the needle-thread loop after it has been released by the loop-taker and holding the same in an open or distended condition across the path of the needle and thereafter releasing the loop subsequent to the passage thereinto of the needle, and means for actuating the loop-holder, of a stationary guard coöperating with the said loop-holder when in loop-holding position for retaining the thread-loop thereon.

3. In a sewing-machine, the combination with a reciprocating needle, a loop-taker, a forked loop-holder operative for receiving the needle-thread loop after it has been released by the loop-taker and holding the same in an open or distended condition across the path of the needle and thereafter releasing the loop subsequent to the passage thereinto of the needle, and means for actuating the loop-holder, of a guard carried by the needle-plate of the sewing-machine coöperating with the said loop-holder when in loop-holding position for retaining the thread-loop thereon.

4. In a sewing-machine, the combination with a reciprocating needle, a loop-taker, a reciprocating forked loop-holder operative for receiving the needle-thread loop after it has been released by the loop-taker and holding the same in an open or distended condition across the path of the needle and thereafter releasing the loop subsequent to the passage thereinto of the needle, and means for actuating the loop-holder, of a stationary guard coöperating with the said loop-holder when in loop-holding position for retaining the thread-loop thereon.

5. In a sewing-machine, the combination with the needle and a loop-taker, of a forked loop-holder operative for receiving the needle-thread loop after it has been released by the loop-taker and holding the same in an open or distended condition across the path of the needle and thereafter releasing the loop subsequent to the passage thereinto of the needle, means for actuating the loop-holder, and a cam-lever carried by said loop-holder for coöperating with a stationary part of the machine to hold the loop-holder in an inoperative position.

6. In a sewing-machine, the combinaton with the needle and a loop-taker, of a forked loop-hoder operative for receiving the needle-thread loop after it has been released by the loop-taker and holding the same in an open or distended condition across the path of the needle and thereafter releasing the loop subsequent to the passage thereinto of the needle, a rock-shaft carrying said loop-holder, and means for operating said rock-shaft.

7. In a sewing-machine, the combination with the needle and a loop-taker, of a forked loop-holder operative for receiving the needle-thread loop after it has been released by the loop-taker and holding the same in an open or distended condition across the path of the needle and thereafter releasing the loop subsequent to the passage thereinto of the needle, a rock-shaft carrying said loop-holder and having a crank-arm, and means for engaging said crank-arm to operate the rock-shaft.

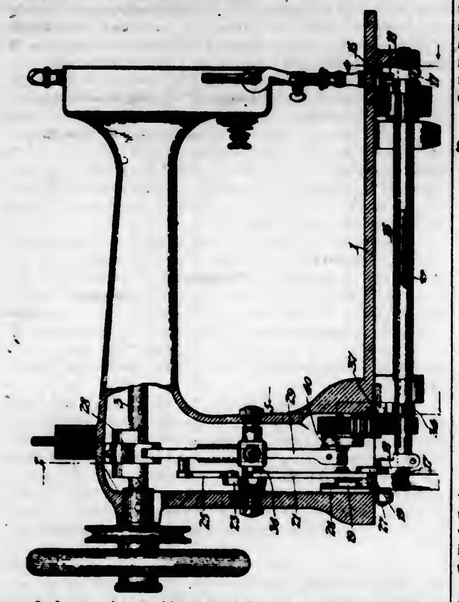
8. In a sewing-machine, the combination with the bed-plate thereof having a hanger at its under side, a rotary loop-taker supported in said hanger, and a reciprocating needle, of a forked loop-holder operative for receiving the needle-thread loop after it has been released by the loop-taker and holding the same in an open or distended condition across the path of the needle and thereafter releasing the loop subsequent to the passage thereinto of the needle, a rock-shaft supported by the hanger and having the said loop-holder and a crank-arm attached thereto at opposite sides of said hanger, and means for engaging said crank-arm to operate the rock-shaft and connected loop-holder.

809,661. **FEEDING MECHANISM FOR SEWING-MACHINES.** WILLIAM M. ASHERMAN, New Haven, Conn., assignor to The Edwin J. Teaf Company, New Haven, Conn., a Corporation of New Jersey. Filed May 4, 1904. Serial No. 206,580.

Claim.—1. In a sewing-machine, a feed device, means for imparting a horizontal movement to said feed device comprising a reciprocatory actuating device, a rock-shaft having two arms one of which is connected with the feed device, a toggle having connection with the second rock-shaft arm, and means including a pivoted lever and a plurality of links operatively connecting the said actuating device and the said toggle, and means for imparting a vertical movement to the feed device.

2. In a sewing-machine, a feed device, means for imparting a horizontal movement to said feed device comprising a reciprocatory actuating device, a rock-shaft having two arms one of which is connected with the feed device, a toggle having connection with the second rock-shaft arm, and a pivoted lever having its opposite ends

operatively connected through the medium of links with the said actuating device and the said toggle respectively, and means for imparting a vertical movement to the feed device.



3. In a sewing-machine, a feed device, means for imparting a horizontal movement to said feed device comprising a driving-shaft, a pitman-lever operated from said shaft, a rock-shaft having two arms, one of which is connected with the feed device, a toggle having connection with the second rock-shaft arm, and a pivoted lever having connection with the pitman-lever through the medium of a link and also having connection with said toggle through the medium of a second link, and means for imparting a vertical movement to the feed device.

4. In a sewing-machine, a feed device, means for imparting a horizontal movement to said feed device comprising a driving-shaft, a pitman operated from said shaft and forming part of the shuttle-actuating mechanism, a rock-shaft having two arms one of which is connected with the feed device, a toggle having connection at one end with the second arm of the rock-shaft and at its opposite end having connection with an adjustable support, and a pivoted lever having one arm thereof connected with the said pitman through the medium of a link and its other arm connected with the said toggle through the medium of a second link, and means for imparting a vertical movement to the feed device.

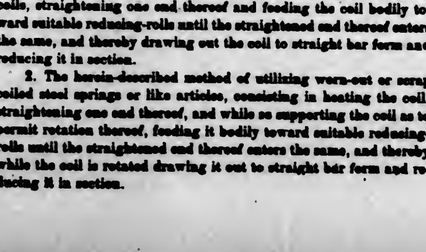
5. In a sewing-machine, a feed device, means for imparting a horizontal movement to said feed device comprising a rock-shaft having two arms one of which is connected with the feed device, a toggle having connection with the second rock-shaft arm, a pivoted lever having connection with said toggle through the medium of a link, and means for actuating said lever and moving the same and the connected link to and from a position at or adjacent to a dead-center, and means for imparting a vertical movement to the feed device.

809,662. **INHALER.** JOSHUA BARKER, New York, N. Y. Filed Aug. 11, 1905. Serial No. 273,701.

Claim.—1. In an inhaler, the combination of a casing; a perforate receptacle within said casing; a partition extending between said receptacle and casing, the latter being provided with an opening on each side of said partition.

2. In an inhaler, the combination of a casing; a perforate receptacle within said casing; a partition extending between said casing and said receptacle; another perforate receptacle within said casing; another partition extending between said casing and said last-named receptacle; the casing being provided with an opening where the said receptacles adjoin, and with further openings located at the other ends of said receptacles.

809,663. **ICE-CREAM MOLD AND DIPPER.** ARTHUR H. BENNETT, Buffalo, N. Y., assignor to The Bennett Manufacturing Company, Buffalo, N. Y., a Corporation of South Dakota. Filed Feb. 10, 1905. Serial No. 244,999.



Claim.—1. In an ice-cream dipper, the combination of a mold or vessel, a handle extending therefrom and having a shank secured to the side of the vessel and provided with an angular eye or washer which extends across the closed end of the vessel, a scraper arranged in the vessel, and a spindle connected with the scraper and passing through said eye or washer, substantially as set forth.

2. In an ice-cream dipper, the combination of a mold or vessel, a handle extending therefrom and having a double shank secured to the side of the vessel and provided with an angular eye which is arranged at the closed end of the vessel, said handle, shank and eye being formed of a continuous piece of wire, and a rotary scraper having an operating-spindle passing through the closed end of the vessel and said eye, substantially as set forth.

3. In an ice-cream dipper, the combination of a mold or vessel, a handle extending therefrom and having a double shank secured to the side of the vessel and terminating in an eye arranged substantially parallel with the handle and secured to the closed end of the vessel, said handle, shank and eye being bent from a single piece of wire the end portions of which are curved to form the eye, and a rotary scraper having an operating-spindle passing through the closed end of the vessel and said eye, substantially as set forth.

4. In an ice-cream dipper, the combination of a mold or vessel, a scraper arranged therein, a spindle connected with the scraper and passing through the closed end of the vessel, a thumb-nut applied to the projecting end of the spindle, and a stop-screw engaging the bore of the nut and bearing against the spindle, substantially as set forth.

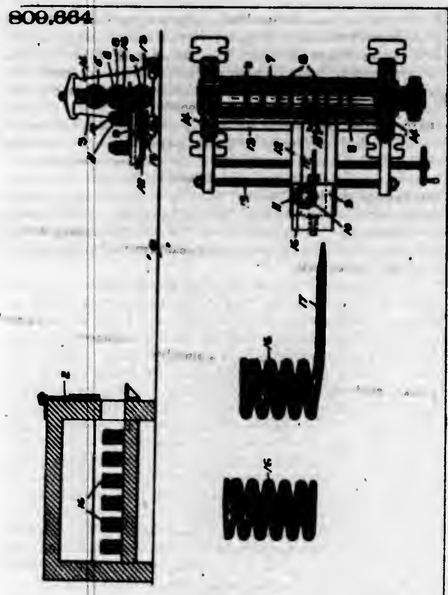
5. In an ice-cream dipper, the combination of a mold or vessel, a scraper arranged therein, a spindle connected with the scraper and passing through the closed end of the vessel, the spindle having a tapered outer end, a thumb-nut applied to the protecting end of the spindle, and a locking-screw engaging the bore of the nut and having a split inner end adapted to be expanded by the tapered end of the spindle, substantially as set forth.

809,664. **METHOD OF UTILIZING WORN-OUT RAILROAD OR LIKE SPIRAL STEEL SPRINGS.** JOHN BERGMANN, Pittsburg, Pa. Filed Mar. 9, 1904. Serial No. 197,266.

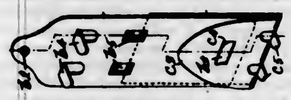
Claim.—1. The herein-described method of utilizing worn-out or scrap coiled steel springs or like articles, consisting in heating the coils, straightening one end thereof and feeding the coil bodily toward suitable reducing-rolls until the straightened end thereof enters the same, and thereby drawing out the coil to straight bar form and reducing it in section.

2. The herein-described method of utilizing worn-out or scrap coiled steel springs or like articles, consisting in heating the coil, straightening one end thereof, and while so supporting the coil as to permit rotation thereof, feeding it bodily toward suitable reducing-rolls until the straightened end thereof enters the same, and thereby while the coil is rotated drawing it out to straight bar form and reducing it in section.

809,664



809,665. **HOLDER FOR MATCH-BOXES.** JOHN BERRYMAN, Clifton, Bristol, England. Filed Sept. 1, 1905. Serial No. 276,705.



Claim.—1. A match-box holder, comprising top and bottom parts, the top part comprising a plate provided near its upper end with forwardly-directed lugs and at a predetermined distance below said lugs with backwardly and downwardly directed tongues, said plate being also provided near its lower end with a forwardly and upwardly directed tongue; and the bottom part being also composed of a plate the lower end of which is bent forwardly and upwardly to form a spring-tongue having a transverse opening, and said bottom part being also provided at its lower end with forwardly-directed lugs, substantially as shown and described.

2. A match-box holder, composed of top and bottom parts, the top part being composed of a plate provided at its upper end with forwardly-directed lugs and beneath said lugs with backwardly and downwardly directed tongues; and the bottom part being also composed of a plate having forwardly-directed lugs at its lower end and provided with a forwardly and upwardly directed spring-tongue, and means for locking the lower end of the top part and said spring-tongue together, substantially as shown and described.

809,666. **WHEEL-HUB.** CHARLES C. BRADANT and WILLIAM C. BRADFORD, Alpena, Mich. Filed Apr. 12, 1905. Serial No. 255,132.

Claim.—1. In a wheel-hub, the combination of a central portion, a casing loosely surrounding the said central portion, a spring contained in the casing and interposed between the same and the central portion for sustaining said central portion and preventing the transmission of shock and jar thereto, antifriction devices interposed between the said spring and the central portion, antifriction devices interposed between the spring and the casing, and one or more other springs interposed between and connected to the central portion and the casing and adapted to connect the casing and the central portion so as to yieldingly transmit motion from one to the other.

2. In a wheel-hub, the combination of a central portion, a casing loosely surrounding the said central portion, a spring contained in the casing and arranged between the casing and the central portion and free from one of said parts; the said spring being designed to sustain the central portion and prevent the transmission of shock and jar thereto, and one or more other springs interposed between and fixed to the central portion and the part of the casing surrounding the central portion so as to transmit motion from the former to the latter.

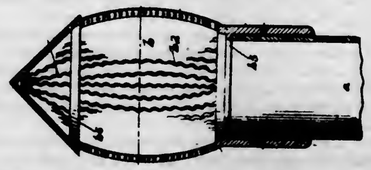
3. In a wheel-hub, the combination of a central portion, a casing loosely surrounding the said central portion, a spring contained in the casing and arranged between the casing and the central portion and free from one of said parts; the said spring being designed to sustain the central portion and prevent the transmission of shock and jar thereto, and other springs interposed between the central portion and the casing; the latter springs having bights at their inner ends provided with lateral trunnions journaled in the central portion and also having their outer ends connected to the casing.

4. In a wheel-hub, the combination of a central portion, a casing loosely surrounding the said central portion, an annulus arranged in the casing, antifriction devices interposed between the annulus and the casing, a sleeve surrounding the central portion, antifriction devices interposed between the sleeve and the central portion, a coiled spring surrounding the sleeve and connected to the sleeve and the annulus, and other springs arranged at the side of the coiled spring and interposed between and connected to the central portion and the casing.

5. In a wheel-hub, the combination of a central portion having a collar provided with transverse sockets, a washer removably secured on said central portion and having transverse sockets, a casing loosely surrounding the central portion and having interior teats or projections, and springs having apertures receiving said teats or projections and also having trunnions disposed in the sockets of the collar and washer.

6. In a wheel-hub, the combination of a central portion having a collar provided with transverse sockets, and also having a shoulder *p* and exterior threads *q*, a nut mounted on said central portion in engagement with the thread *q* thereof and bearing a collar, a washer interposed between said nut and the shoulder *p*, and having transverse sockets, a ring, of yielding material, surrounding the nut and interposed between the collar thereon and the washer, a casing loosely surrounding the central portion and having interior teats or projections, a flexible, bellows-like wall connecting the ring and the casing, springs having apertures receiving the teats or projections of the casing and also having lateral trunnions disposed in the sockets of the collar and washer, and a coiled spring arranged in the casing alongside the first-mentioned springs and surrounding the central portion and interposed between the same and the casing.

809,667. **GUARD FOR VENT-PIPES.** CORNELIUS H. BRESH New York, N. Y. Filed Nov. 18, 1903. Serial No. 181,596.



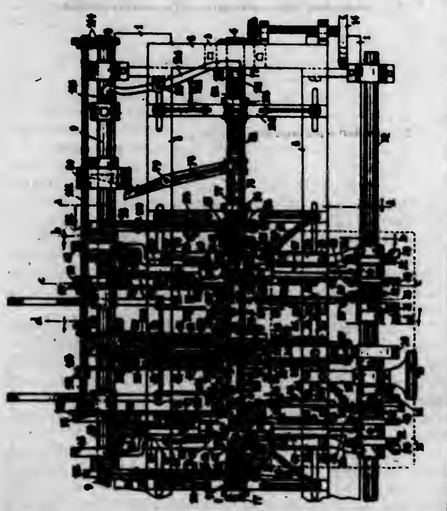
Claim.—1. A guard for vent-pipes, comprising a plurality of vertically-disposed ribs or bars connected at their lower ends with a circular bottom portion, adapted to be placed on a vent or ventilating pipe, and at their upper ends with a conical top having similar ribs or bars all of said ribs or bars being corrugated, substantially as described.

2. A guard for vent-pipes, comprising a body portion composed of a plurality of vertically-arranged flat ribs or bars, having their greatest extent in a radial direction, said ribs or bars being connected at their lower ends with a pipe member adapted to be secured to a vent or ventilating pipe and at their upper ends with a bend forming

the lower part of a conical top having similarly-disposed flat bars, all of said ribs or bars being corrugated, substantially as described.

3. A guard for vent-pipes, comprising a bottom portion of unbroken circular form, a body portion composed of flat ribs or bars having their greatest extent in a radial direction and a conical top portion having similarly-disposed flat bars, the top bars not being continuous with those of the body portion but united thereto by a ring or band to which both series of bars are connected, the outer surface of the top bars being flush with the outer surface of the said ring or band substantially as described.

809,668. HEDDLE-MAKING MACHINE. EDMOND CHARPENTIER and JOSEPH REMBLER, Verviers, Belgium. Filed May 29, 1905. Serial No. 262,269.



Claim.—1. In a machine for manufacturing metallic healds for looms by means of blanks formed of a double wire section, previously cut to the desired length, the combination with a suitable frame, a main shaft arranged in the center line and above said frame, a cam-shaft on each side and above said main shaft, and a secondary frame above the main frame; of a plurality of reciprocating and tipping forks adapted to receive the blanks one by one, a plurality of movable claws, and stationary supports adapted to receive the blanks from said tipping forks and hold the same during the formation of the eyes of the heald, means for reciprocating and tipping said forks, means for rotating said claws; longitudinally-movable spindles in line with said stationary supports, eye-forming studs carried thereby, reciprocating means for folding the ends of the blank around said studs, longitudinally-reciprocating matrices adapted to be brought over said studs after the folding of the ends of the blank, pairs of oppositely-arranged claws adapted to clamp between them the portions of the blank adjacent to the extreme eyes of the heald, means for rotating said studs and matrices for twisting the eyes of the heald, means for simultaneously forming the central eye of the heald, means for disengaging the completed heald from the eye-forming studs, and means for taking the completed heald from said retaining-claws, substantially as set forth.

2. In a machine for manufacturing metallic healds of the class described, the combination with a main frame, a main shaft arranged in the center line and above said frame, a cam-shaft on each side of and above said main shaft and suitable connections between the latter and the cam-shafts; of a plurality of reciprocating and tipping forks adapted to receive one blank at a time, means on one of said cam-shafts for reciprocating and tipping said forks, a plurality of oppositely-arranged coöperating claws, two suitable supports carried by certain claws and adapted to receive the blank from said forks when tipped and hold the same during the formation of the heald, means on the cam-shafts for moving said claws toward each other when the blank is received upon said supports and between said claws, suitable guides for the ends of the blank, eye-forming studs arranged in line with said supports and adapted to be engaged by the end portions of the blank, reciprocating slide-blocks near said guides, horizontally-swinging levers on said slide-blocks, adapted to engage the end portions of the blank and fold the same around the eye-forming studs, oppositely-arranged means for closing the eyes formed around said studs, reciprocating coöperating claws adapted to clamp between them the portions of the blank adjacent to the extreme eyes, means for forming simultaneously the central eye of the heald between the stationary supports, means for twisting the portions of the heald adjacent to the extreme eyes, means for twisting the portions of the blank adjacent to the central eye, means for causing the several pairs of claws to produce a supplemental clamping action upon the blank during the twisting thereof, means for disengaging the completed heald from the eye-forming devices, and means for taking the completed heald from said supports, substantially as set forth.

3. In a machine for manufacturing metallic healds of the class described, the combination with a main frame, a main shaft arranged in the center line and above said frame, a cam-shaft on each side of and above said main shaft, and suitable connections between the latter and the cam-shafts; of a plurality of reciprocating and tipping forks adapted to receive one blank at a time, means on one of said cam-shafts for reciprocating and tipping said forks, a plurality of oppositely-arranged coöperating claws, horizontally-reciprocating slide-blocks carrying said claws, stationary guideways for said slide-blocks, cams for reciprocating the same toward and apart from each other, means for causing the claws to produce an elastic pressure upon the blank between them, fork-shaped supports carried by certain claws and adapted to receive the blank from the aforesaid forks so that the same lies between the claws and is held by the latter during the formation of the heald, suitable guides for the ends of the blank, eye-forming studs arranged in line with said supports and adapted to be engaged by the end portion of the blank, reciprocating slide-blocks near said guides, horizontally-swinging levers on said slide-blocks adapted to engage the end portions of the blank and fold the same around the eye-forming studs, oppositely-arranged means for closing the eyes formed around said studs, reciprocating coöperating claws adapted to clamp between them the portions of the blank adjacent to the extreme eyes, means for forming simultaneously the central eye of the heald between the stationary supports, means for twisting the portions of the heald adjacent to the extreme eyes, means for twisting the portions of the blank adjacent to the central eye, means for causing the several pairs of claws to produce a supplemental clamping action upon the blank during the twisting thereof, means for disengaging the completed heald from the eye-forming devices, and means for taking the completed heald from said supports, substantially as set forth.

4. In a machine for manufacturing metallic healds of the class described, the combination with a main frame, a main shaft arranged in the center line and above said frame, a cam-shaft on each side of and above said main shaft and suitable connections between the latter and the cam-shafts; of a plurality of reciprocating and tipping forks adapted to receive one blank at a time, means on one of said cam-shafts for reciprocating and tipping said forks, a plurality of oppositely-arranged coöperating claws, horizontally-reciprocating slide-blocks carrying said claws, stationary guideways for said slide-blocks, cams for reciprocating the same toward and apart from each other, means for causing the claws to produce an elastic pressure upon the blank between them, fork-shaped supports carried by certain claws and adapted to receive the blank from the aforesaid forks so that the same lies between the claws and is held by the latter during the formation of the heald, a toothed pinion journaled on a stationary part between said claws, means carried by said pinion and adapted to separate the wires of the blank for the formation of the central eye of the heald, means for rotating said pinion at a given moment for twisting the portions of the blank adjacent to said central eye, suitable guides for the ends of the blank, eye-forming studs arranged in line with said supports and adapted to be engaged by the end portions of the blank, means for folding said end portions around said studs for the formation of the extreme eyes of the heald, oppositely-arranged means for closing the eyes formed around said studs, means for clamping between them the end portions of the blank, means for twisting the portions of the blank adjacent to the extreme eyes, means for causing the several pairs of clamping means to produce a supplemental clamping action during the twisting of the several portions of the blank, means for disengaging the completed heald from the eye-forming devices, and means for taking the completed heald automatically from the supports carried by the central claws, substantially as set forth.

5. In a machine for manufacturing metallic healds of the class described, the combination with a main frame, a main shaft arranged in the center line and above said frame, a cam-shaft on each side of and above said main shaft and suitable connections between the latter and the cam-shafts; of a plurality of reciprocating and tipping forks adapted to receive one blank at a time, means on one of said cam-shafts for reciprocating and tipping said forks, a plurality of oppositely-arranged coöperating claws, horizontally-reciprocating slide-blocks carrying said claws, stationary guideways for said slide-blocks, cams for reciprocating the same toward and apart from each other, means for causing the claws to produce an elastic pressure upon the blank between them, fork-shaped supports carried by certain claws and adapted to receive the blank from the aforesaid forks so that the same lies between the claws and is held by the latter during the formation of the heald, a toothed pinion journaled on a stationary part between said claws, means carried by said pinion and adapted to separate the wires of the blank for the formation of the central eye of the heald, means for rotating said pinion at a given moment for twisting the portions of the blank adjacent to said central eye, suitable guides for the ends of the blank, eye-forming studs arranged in line with said supports and adapted to be engaged by the end portions of the blank, means for folding said end portions around said studs for the formation of the extreme eyes of the heald, oppositely-arranged means for closing the eyes formed around said studs, means for clamping between them the end portions of the blank, means for twisting the portions of the blank adjacent to the extreme eyes, means for causing the several pairs of clamping means to produce a supplemental clamping action during the twisting of the several portions of the blank, means for disengaging the completed heald from the eye-forming devices, and means for taking the completed heald automatically from the supports carried by the central claws, substantially as set forth.

6. In a machine for manufacturing metallic healds of the class described, the combination with a main frame, a main shaft arranged in the center line and above said frame, a cam-shaft on each side of and above said main shaft and suitable connections between the latter and the cam-shafts; of a plurality of reciprocating and tipping forks adapted to receive one blank at a time, means on one of said cam-shafts for reciprocating and tipping said forks, a plurality of oppositely-arranged coöperating claws, horizontally-reciprocating slide-blocks carrying said claws, stationary guideways for said slide-blocks, cams for reciprocating the same toward and apart from each other, means for causing the claws to produce an elastic pressure upon the blank between them, fork-shaped supports carried by certain claws and adapted to receive the blank from the aforesaid forks so that the same lies between the claws and is held by the latter during the formation of the heald, a toothed pinion journaled on a stationary part between said claws, a pointed pin arranged horizontally in the interior of the hub of said pinion, a horizontal slot in the latter through which the blank is brought into engagement with said pointed pin when the blank-carrying supports are moved forwardly, means for rotating said pinion at a given moment for twisting the portion of the blank adjacent to said central eye, suitable guides for the ends of the blank, eye-forming studs arranged in line with said supports and adapted to be engaged by the end portions of the blank, means for folding said end portions around said studs for the formation of the extreme eyes of the heald, oppositely-arranged means for closing the eyes formed around said studs, means for clamping between them the end portions of the blank, means for twisting the portions of the blank adjacent to the extreme eyes, means for causing the several pairs of clamping means to produce a supplemental clamping action during the twisting of the several portions of the blank, means for disengaging the completed heald from the eye-forming devices, and means for taking the completed heald automatically from the supports carried by the central claws, substantially as set forth.

7. In a machine for manufacturing metallic healds of the class described, the combination with a main frame, a main shaft arranged in the center line and above said frame, a cam-shaft on each side of and above said main shaft and suitable connections between the latter and the cam-shafts; of a plurality of reciprocating and tipping forks adapted to receive one blank at a time, means on one of said cam-shafts for reciprocating and tipping said forks, a plurality of oppositely-arranged coöperating claws, horizontally-reciprocating slide-blocks carrying said claws, stationary guideways for said slide-blocks, cams for reciprocating the same toward and apart from each other, means for causing the claws to produce an elastic pressure upon the blank between them, fork-shaped supports carried by certain claws and adapted to receive the blank from the aforesaid forks so that the same lies between the claws and is held by the latter during the formation of the heald, a toothed pinion journaled on a stationary part between said claws, means carried by said pinion and adapted to separate the wires of the blank for the formation of the central eye of the heald, a circular disk arranged on the main shaft of the machine and rotating with the same, a number of teeth on the periphery of said disk and adapted to mesh with said toothed pinion at a given moment to rotate the same and twist the portions of the blank adjacent to said central eye, means for temporarily locking the toothed pinion against rotation, suitable guides for the ends of the blank, eye-forming studs arranged in line with said supports and adapted to be engaged by the end portions of the blank, means for folding said end portions around said studs for the formation of the extreme eyes of the heald, oppositely-arranged means for closing the eyes formed around said studs, means for clamping between them the end portions of the blank, means for twisting the portions of the blank adjacent to the extreme eyes, means for causing the several pairs of clamping means to produce a supplemental clamping action during the twisting of the several portions of the blank, means for disengaging the completed heald from the eye-forming devices, and means for taking the completed heald automatically from the supports carried by the central claws, substantially as set forth.

8. In a machine for manufacturing metallic healds of the class described, the combination with a main frame, a main shaft arranged in the center line and above said frame, a cam-shaft on each side of and above said main shaft, and suitable connections between the latter and the cam-shafts; of a plurality of reciprocating and tipping forks adapted to receive one blank at a time, means on one of said cam-shafts for successively reciprocating and tipping said forks, a plurality of oppositely-arranged coöperating claws, horizontally-reciprocating slide-blocks carrying said claws, stationary guideways for said slide-blocks, a cam on one cam-shaft for actuating the claws on one side against the action of suitable springs, said springs, a suitable cam on the main shaft, a vertically-swinging lever adapted to be engaged at a given moment by said cam and press the claws on the other side strongly against the opposite claws, fork-shaped supports carried by certain claws and adapted to receive the blank from the aforesaid forks so that the same lies between the claws and is held by the latter during the formation of the heald, suitable guides for the ends of the blank, eye-forming studs arranged in line with said supports and adapted to be engaged by the end portion of the blank, reciprocating slide-blocks near said guides, horizontally-swinging levers on said slide-blocks adapted to engage the end portions of the blank and fold the same around the eye-forming studs, oppositely-arranged means for closing the eyes formed around said studs, reciprocating coöperating claws adapted to clamp between them the portions for the blank adjacent to the extreme eyes, means for forming simultaneously the central eye of the heald between the stationary supports, means for twisting the portions of the heald adjacent to the extreme eyes, means for twisting the portions of the blank adjacent to the central eye, means for causing the several pairs of claws to produce a supplemental clamping action upon the blank during the twisting thereof, means for disengaging the completed heald from the eye-forming devices, and means for taking the completed heald from said supports, substantially as set forth.

9. In a machine for manufacturing metallic healds of the class described, the combination with a main frame, a main shaft arranged in the center line and above said frame, a cam-shaft on each side of and above said main shaft, and suitable connection between the latter and the cam-shafts; of a plurality of reciprocating and tipping forks adapted to receive one blank at a time, means on one of said cam-shafts for reciprocating and tipping said forks, a plurality of oppositely-arranged coöperating claws, two suitable supports carried by certain claws and adapted to receive the blank from the forks when tipped and hold the same during the formation of the heald, means on the cam-shafts for moving said claws toward each other when the blank is received upon said supports and between said claws, suitable guides for the ends of the blank, eye-forming studs arranged in line with said supports and adapted to be engaged by the end portions of the blank, reciprocating slide-blocks near said guides, horizontally-swinging levers on said slide-blocks, adapted to engage the end portions of the blank and fold the same around the eye-forming studs, oppositely-arranged means for closing the eyes formed around said studs, reciprocating coöperating claws adapted to clamp between them the portions of the blank adjacent to the extreme eyes, means for forming simultaneously the central eye of the heald between the stationary supports, means for twisting the portions of the heald adjacent to the extreme eyes, means for twisting the portions of the blank adjacent to the central eye, means for causing the several pairs of claws to produce a supplemental clamping action upon the blank during the twisting thereof, means for disengaging the completed heald from the eye-forming devices, and means for taking the completed heald from said supports, substantially as set forth.

10. In a machine for manufacturing metallic healds of the class described, the combination with a main frame, a main shaft arranged in the center line and above said frame, a cam-shaft on each side of and above said main shaft and suitable connections between the latter and the cam-shafts; of a plurality of reciprocating and tipping forks adapted to receive one blank at a time, means on one of said cam-shafts for reciprocating and tipping said forks, a plurality of oppositely-arranged coöperating claws, two suitable supports carried by certain claws and adapted to receive the blank from said forks when tipped and hold the same during the formation of the heald, means on the cam-shafts for moving said claws toward each other when the blank is received upon said supports and between said claws, suitable guides for the ends of the blank, eye-forming studs arranged in line with said supports and adapted to be engaged by the end portions of the blank, reciprocating slide-blocks near said guides, horizontally-swinging levers on said slide-blocks adapted to engage the end portions of the blank and fold the same around the eye-forming studs, oppositely-arranged means for closing the eyes formed around said studs, reciprocating coöperating claws adapted to clamp between them the portions of the blank adjacent to the extreme eyes, means for forming simultaneously the central eye of the heald between the stationary supports, means for twisting the portions of the heald adjacent to the extreme eyes, means for twisting the portions of the blank adjacent to the central eye, means for causing the several pairs of claws to produce a supplemental clamping action upon the blank during the twisting thereof, means for disengaging the completed heald from the eye-forming devices, and means for taking the completed heald from said supports, substantially as set forth.

11. In a machine for manufacturing metallic healds of the class described, the combination with a main frame, a main shaft arranged in the center line and above said frame, a cam-shaft on each side of and above said main shaft and suitable connections between the latter and the cam-shafts; of a plurality of reciprocating and tipping forks adapted to receive one blank at a time, means on one of said cam-shafts for reciprocating and tipping said forks, a plurality of oppositely-arranged coöperating claws, horizontally-reciprocating slide-blocks carrying said claws, stationary guideways for said slide-blocks, cams for reciprocating the same toward and apart from each other, means for causing the claws to produce an elastic pressure upon the blank between them, fork-shaped supports carried by certain claws and adapted to receive the blank from the aforesaid forks so that the same lies between the claws and is held by the latter during the formation of the heald, suitable guides for the ends of the blank, eye-forming studs arranged in line with said supports and adapted to be engaged by the end portion of the blank, reciprocating slide-blocks near said guides, horizontally-swinging levers on said slide-blocks adapted to engage the end portions of the blank and fold the same around the eye-forming studs, oppositely-arranged means for closing the eyes formed around said studs, reciprocating coöperating claws adapted to clamp between them the portions of the blank adjacent to the extreme eyes, means for forming simultaneously the central eye of the heald between the stationary supports, means for twisting the portions of the heald adjacent to the extreme eyes, means for twisting the portions of the blank adjacent to the central eye, means for causing the several pairs of claws to produce a supplemental clamping action upon the blank during the twisting thereof, means for disengaging the completed heald from the eye-forming devices, and means for taking the completed heald from said supports, substantially as set forth.

12. In a machine for manufacturing metallic healds of the class described, the combination with a main frame, a main shaft arranged in the center line and above said frame, a cam-shaft on each side of and above said main shaft and suitable connections between the latter and the cam-shafts; of a plurality of reciprocating and tipping forks adapted to receive one blank at a time, means on one of said cam-shafts for reciprocating and tipping said forks, a plurality of oppositely-arranged coöperating claws, two suitable supports carried by certain claws and adapted to receive the blank from said forks when tipped and hold the same during the formation of the heald, means on the cam-shafts for moving said claws toward each other when the blank is received upon said supports and between said claws, suitable guides for the ends of the blank, eye-forming studs arranged in line with said supports and adapted to be engaged by the end portions of the blank, reciprocating slide-blocks near said guides, horizontally-swinging levers on said slide-blocks adapted to engage the end portions of the blank and fold the same around the eye-forming studs, oppositely-arranged means for closing the eyes formed around said studs, reciprocating coöperating claws adapted to clamp between them the portions of the blank adjacent to the extreme eyes, means for forming simultaneously the central eye of the heald between the stationary supports, means for twisting the portions of the heald adjacent to the extreme eyes, means for twisting the portions of the blank adjacent to the central eye, means for causing the several pairs of claws to produce a supplemental clamping action upon the blank during the twisting thereof, means for disengaging the completed heald from the eye-forming devices, and means for taking the completed heald from said supports, substantially as set forth.

13. In a machine for manufacturing metallic healds of the class described, the combination with a main frame, a main shaft arranged in the center line and above said frame, a cam-shaft on each side of and above said main shaft and suitable connections between the latter and the cam-shafts; of a plurality of reciprocating and tipping forks adapted to receive one blank at a time, means on one of said cam-shafts for reciprocating and tipping said forks, a plurality of oppositely-arranged coöperating claws, horizontally-reciprocating slide-blocks carrying said claws, stationary guideways for said slide-blocks, cams for reciprocating the same toward and apart from each other, means for causing the claws to produce an elastic pressure upon the blank between them, fork-shaped supports carried by certain claws and adapted to receive the blank from the aforesaid forks so that the same lies between the claws and is held by the latter during the formation of the heald, suitable guides for the ends of the blank, eye-forming studs arranged in line with said supports and adapted to be engaged by the end portion of the blank, reciprocating slide-blocks near said guides, horizontally-swinging levers on said slide-blocks adapted to engage the end portions of the blank and fold the same around the eye-forming studs, oppositely-arranged means for closing the eyes formed around said studs, reciprocating coöperating claws adapted to clamp between them the portions of the blank adjacent to the extreme eyes, means for forming simultaneously the central eye of the heald between the stationary supports, means for twisting the portions of the heald adjacent to the extreme eyes, means for twisting the portions of the blank adjacent to the central eye, means for causing the several pairs of claws to produce a supplemental clamping action upon the blank during the twisting thereof, means for disengaging the completed heald from the eye-forming devices, reciprocating matrices on each side of the machine and adapted to be moved over said eye-forming studs, square spindles carrying said reciprocating matrices, means for rotating the matrices when they are engaged

over the eye-forming studs, means for rotating simultaneously central eye-forming devices, means for causing the several pairs of claws to produce a supplemental clamping action during the rotation of the eye-forming devices, means for disengaging the heald from the eye-forming devices, and means for taking the completed heald from said retaining-supports, substantially as set forth.

10. In a machine for manufacturing metallic healds of the class described, the combination with a main frame, a main shaft arranged in the center line and above said frame, a cam-shaft on each side of and above said main shaft, and suitable connection between the latter and the cam-shafts; of a plurality of reciprocating and tipping forks adapted to receive one blank at a time, means on one of said cam-shafts for reciprocating and tipping said forks, a plurality of oppositely-arranged coöperating claws, two suitable supports carried by certain claws and adapted to receive the blank from the forks when tipped and hold the same during the formation of the heald, means on the cam-shafts for moving said claws toward each other when the blank is received upon said supports and between said claws, suitable guides for the ends of the blank, eye-forming studs arranged in line with said supports and adapted to be engaged by the end portions of the blank, reciprocating slide-blocks near said guides, horizontally-swinging levers on said slide-blocks, adapted to engage the end portions of the blank and fold the same around the eye-forming studs, oppositely-arranged means for closing the eyes formed around said studs, reciprocating coöperating claws adapted to clamp between them the portions of the blank adjacent to the extreme eyes, means for forming simultaneously the central eye of the heald between the stationary supports, reciprocating matrices on each side of the machine and adapted to be moved over said eye-forming studs, square spindles carrying said reciprocating matrices, means for reciprocating the matrices on said square spindles, toothed pinions on the latter, means for temporarily locking said pinions against rotation, and means for disengaging said locking means at a given moment, circular disks on the main shaft, toothed peripheral portions on said disk adapted to mesh with said pinions when the same are unlocked, to rotate said pinions, the square spindles and the matrices, means for simultaneously rotating the central eye-forming devices, means for causing the several clamping-claws to produce a supplemental clamping action during the rotation of the square spindles and the central eye-forming devices, horizontally-swinging levers on the frame of the machine and normally engaging the ends of said square spindles, cams on one cam-shaft for actuating said levers so that the spindles and therefor the eye-forming studs are brought nearer to each other for disengaging the eyes from said studs, means for raising the complete heald above said studs, and means for taking the complete heald from its supports, substantially as set forth.

11. In a machine for manufacturing metallic healds of the class described, the combination with a main frame, a main shaft arranged in the center line and above said frame, a cam-shaft on each side of and above said main shaft, and suitable connection between the latter and the cam-shafts; of a plurality of reciprocating and tipping forks adapted to receive one blank at a time, means on one of said cam-shafts for reciprocating and tipping said forks, a plurality of oppositely-arranged coöperating claws, two suitable supports carried by certain claws and adapted to receive the blank from forks when tipped and hold the same during the formation of the heald, means on the cam-shafts for moving said claws toward each other when the blank is received upon said supports and between said claws, suitable guides for the ends of the blank, eye-forming studs arranged in line with said supports and adapted to be engaged by the end portions of the blank, reciprocating slide-blocks near said guides, horizontally-swinging levers on said slide-blocks, adapted to engage the end portions of the blank and fold the same around the eye-forming studs, oppositely-arranged means for closing the eyes formed around said studs, reciprocating coöperating claws adapted to clamp between them the portions of the blank adjacent to the extreme eyes, means for forming simultaneously the central eye of the heald between the stationary supports, reciprocating matrices on each side of the machine and adapted to be moved over said eye-forming studs, square spindles carrying said reciprocating matrices, means for reciprocating the matrices on said square spindles, toothed pinions on the latter, grooved sockets attached to said pinions, balance-levers supported on the frame of the machine in proximity to said pinions, pins carried by said balance-levers and normally engaging the grooved sockets to hold the pinions against rotation, means for holding said pins in engagement with said sockets, cams on one cam-shaft adapted to engage said balance-levers and disengage said pins from said sockets, circular disks on the main shaft, toothed peripheral portions on said disks adapted to mesh with said pinions when the same are unlocked, to rotate said pinions, the square spindles and the matrices, means for simultaneously rotating the central eye-forming devices, means for causing the several clamping-claws to produce a supplemental clamping action during the rotation of the square spindles and the central eye-forming devices, horizontally-swinging levers on the frame of the machine and normally engaging the ends of said square spindles, cams on one cam-shaft for actuating said levers so that the spindles and therefore the eye-forming studs are brought nearer to each other for disengaging the eyes from said studs, means for raising the complete heald above said studs, and means for taking the complete heald from its supports, substantially as set forth.

12. In a machine for manufacturing metallic healds of the class described, the combination with a main frame, a main shaft arranged in the center line and above said frame, a cam-shaft on each side of and above said main shaft, and suitable connection between the latter and the cam-shafts; of a plurality of reciprocating and tipping forks adapted to receive one blank at a time, means on one of said cam-shafts for reciprocating and tipping said forks, a plurality of oppositely-coöperating claws, two suitable supports carried by certain claws and adapted to receive the blank from forks when tipped and hold the same during the formation of the heald, means on the cam-shafts for moving said claws toward each other when the blank is received upon said supports and between said claws, suitable guides for the ends of the blank, eye-forming studs arranged in line with said supports and adapted to be engaged by the end portions of the blank, reciprocating slide-blocks near said guides, horizontally-swinging levers on said slide-blocks, adapted to engage the end portions of the blank and fold the same around the eye-forming studs, oppositely-arranged means for closing the eyes formed around said studs, reciprocating coöperating claws adapted to clamp between them the portions of the blank adjacent to the extreme eyes, means for forming simultaneously the central eye of the heald between the stationary supports, reciprocating matrices on each side of the machine and adapted to be moved over said eye-forming studs, square spindles carrying said reciprocating matrices, means for reciprocating the matrices on said square spindles, toothed pinions on the latter, means for temporarily locking said pinions against rotation, and means for disengaging said locking means at a given moment, circular disks on the main shaft, toothed peripheral portions on said disks adapted to mesh with said pinions when the same are unlocked, to rotate said pinions, the square spindles and the matrices, means for simultaneously rotating the central eye-forming devices, means for causing the several clamping-claws to produce a supplemental clamping action during the rotation of the square spindles and the central eye-forming devices, horizontally-swinging levers on the frame of the machine and normally engaging the ends of said square spindles, cams on one cam-shaft for actuating said levers so that the spindles and therefore the eye-forming studs are brought nearer to

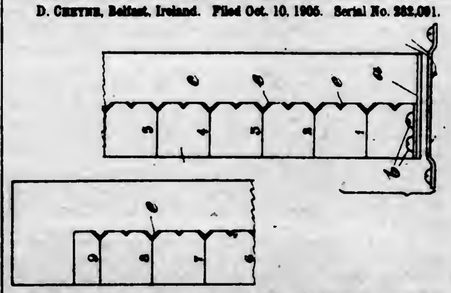
each other for disengaging the eyes from said studs, vertically-movable bars arranged below the eye-forming studs and adapted to engage and raise the heald above the same after the disengagement of said studs, means for normally pulling said vertical bars downwardly, cams on the main shaft, means engaged by said cams to raise said vertical bars, and means for taking the complete heald from its supports, substantially as described.

14. In a machine for manufacturing metallic healds of the class described, the combination with a main frame, a main shaft arranged in the center line and above said frame, a cam-shaft on each side of and above said main shaft, and suitable connection between the latter and the cam-shafts; of a plurality of reciprocating and tipping forks adapted to receive one blank at a time, means on one of said cam-shafts for reciprocating and tipping said forks, a plurality of oppositely-coöperating claws, two suitable supports carried by certain claws and adapted to receive the blank from forks when tipped and hold the same during the formation of the heald, means on the cam-shafts for moving said claws toward each other when the blank is received upon said supports and between said claws, suitable guides for the ends of the blank, eye-forming studs arranged in line with said supports and adapted to be engaged by the end portions of the blank, reciprocating slide-blocks near said guides, horizontally-swinging levers on said slide-blocks, adapted to engage the end portions of the blank and fold the same around the eye-forming studs, oppositely-arranged means for closing the eyes formed around said studs, reciprocating coöperating claws adapted to clamp between them the portions of the blank adjacent to the extreme eyes, means for forming simultaneously the central eye of the heald between the stationary supports, reciprocating matrices on each side of the machine and adapted to be moved over said eye-forming studs, square spindles carrying said reciprocating matrices, means for reciprocating the matrices on said square spindles, toothed pinions on the latter, means for temporarily locking said pinions against rotation, and means for disengaging said locking means at a given moment, circular disks on the main shaft, toothed peripheral portions on said disks adapted to mesh with said pinions when the same are unlocked, to rotate said pinions, the square spindles and the matrices, means for simultaneously rotating the central eye-forming devices, means for causing the several clamping-claws to produce a supplemental clamping action during the rotation of the square spindles and the central eye-forming devices, horizontally-swinging levers on the frame of the machine and normally engaging the ends of said square spindles, cams on one cam-shaft for actuating said levers so that the spindles and therefore the eye-forming studs are brought nearer to each other for disengaging the eyes from said studs, means for raising the complete heald above said studs, an auxiliary shaft arranged in proximity to the heald-retaining supports, means for rotating said auxiliary shaft, a plurality of heald takers or pickers secured to said rotating shaft and capable of taking the completed heald from its supports, and means for receiving the heald from said takers and conveying the same to a suitable receptacle, substantially as set forth.

15. In a machine for manufacturing metallic healds of the class described, the combination with a main frame, a main shaft arranged in the center line and above said frame, a cam-shaft on each side of and above said main shaft, and suitable connection between the latter and the cam-shafts; of a plurality of reciprocating and tipping forks adapted to receive one blank at a time, means on one of said cam-shafts for reciprocating and tipping said forks, a plurality of oppositely-coöperating claws, two suitable supports carried by certain claws and adapted to receive the blank from forks when tipped and hold the same during the formation of the heald, means on the cam-shafts for moving said claws toward each other when the blank is received upon said supports and between said claws, suitable guides for the ends of the blank, eye-forming studs arranged in line with said supports and adapted to be engaged by the end portions of the blank, reciprocating slide-blocks near said guides, horizontally-swinging levers on said slide-blocks, adapted to engage the end portions of the blank and fold the same around the eye-forming studs, oppositely-arranged means for closing the eyes formed around said studs, reciprocating coöperating claws adapted to clamp between them the portions of the blank adjacent to the extreme eyes, means for forming simultaneously the central eye of the heald between the stationary supports, reciprocating matrices on each side of the machine and adapted to be moved over said eye-forming studs, square spindles carrying said reciprocating matrices, means for reciprocating the matrices on said square spindles, toothed pinions on the latter, means for temporarily locking said pinions against rotation, and means for disengaging said locking means at a given moment, circular disks on the main shaft, toothed peripheral portions on said disks adapted to mesh with said pinions when the same are unlocked, to rotate said pinions, the square spindles and the matrices, means for simultaneously rotating the central eye-forming devices, means for causing the several clamping-claws to produce a supplemental clamping action during the rotation of the square spindles and the central eye-forming devices, horizontally-swinging levers on the frame of the machine and normally engaging the ends of said square spindles, cams on one cam-shaft for actuating said levers so that the spindles and therefore the eye-forming studs are brought nearer to each other for disengaging the eyes from said studs, means for raising the complete heald above said studs, an auxiliary shaft arranged in proximity to the heald-retaining supports, means for rotating said auxiliary shaft, a plurality of heald takers or pickers secured to said rotating shaft and capable of taking the completed heald from its supports, a second auxiliary shaft, chain-wheels on both auxiliary shafts, and chains passing around said chain-wheels to receive the heald from said takers, and a suitable receptacle at the end of the chains to receive the heald from the same, substantially as set forth.

16. In a machine for manufacturing metallic healds of the class described, the combination with a main frame, a main shaft arranged in the center line and above said frame, a cam-shaft on each side of and above said main shaft, and suitable connection between the latter and the cam-shafts; of a plurality of reciprocating and tipping forks adapted to receive one blank at a time, means on one of said cam-shafts for reciprocating and tipping said forks, a plurality of oppositely-arranged coöperating claws, two suitable supports carried by certain claws and adapted to receive the blank from said forks when tipped and hold the same during the formation of the heald, means on the cam-shafts for moving said claws toward each other when the blank is received upon said supports and between said claws, suitable guides for the ends of the blank, eye-forming studs arranged in line with said supports and adapted to be engaged by the end portions of the blank, reciprocating slide-blocks near said guides, horizontally-swinging levers on said slide-blocks adapted to engage the end portions of the blank and fold the same around the eye-forming studs, oppositely-arranged means for closing the eyes formed around said studs, reciprocating coöperating claws adapted to clamp between them the portions of the blank adjacent to the extreme eyes, means for forming simultaneously the central eye of the heald between the stationary supports, reciprocating matrices on each side of the machine and adapted to be moved over said eye-forming studs, square spindles carrying said reciprocating matrices, means for rotating the matrices when they are engaged over the eye-forming studs, means for rotating simultaneously the central eye-forming devices, means for causing the several pairs of claws to produce a supplemental clamping action during the rotation of the eye-forming devices, means for holding the square spindles yieldingly in the direction of their length, so as to permit the same to follow the tension of the blank to a given extent, means for disengaging the heald from the eye-forming devices, and means for taking the completed heald from its supports, substantially as set forth.

809,669. APPARATUS FOR MEASURING AND MARKING THE DISTANCE FROM THE GROUND OF SKIRTS, &c. SAMUEL D. CHEYNE, Belfast, Ireland. Filed Oct. 10, 1905. Serial No. 282,091.

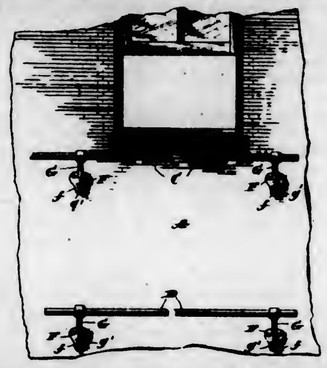


Claim.—1. An apparatus for measuring and marking the distance from the ground of skirts and other garments consisting of a base to which two uprights are fitted at a short distance apart from one another, one of said uprights being marked off with divisions and provided with notches in which the chalk or the like can be rested when marking the garment, substantially as described.

2. An apparatus for measuring and marking the distance from the ground of skirts and other garments comprising, in combination

a base, two uprights fitted to the base and situated a short distance apart from one another, one of said uprights being marked off with divisions and provided with notches in which the chalk or the like can be rested when marking the garment, substantially as described.

809,670. FIRE-ESCAPE. JAMES C. COVERT, Watervliet, N. Y. Original application filed Sept. 19, 1904, Serial No. 225,097. Divided and this application filed Jan. 7, 1905. Serial No. 240,075.



Claim.—1. In a fire-escape, the combination with a plurality of base or supporting members adapted to be secured at desired points upon a building, a hand or foot rail, and a corresponding plurality of supporting-arms carried by and shiftable relative to the said hand or foot rail adapted to be brought into registration with and connected to said base or supporting members.

2. In a fire-escape, the combination with a plurality of base or supporting members adapted to be secured at desired points upon a building, a hand or foot rail, and a corresponding plurality of supporting-arms carried by and shiftable relative to the said hand or foot rail adapted to be brought into registration with and connected to said base or supporting members, said supporting-arms and the base or supporting members being separable in a vertical direction.

3. In a fire-escape, the combination with a plurality of base or supporting members adapted to be secured at desired points upon a building, a hand or foot rail, and a corresponding plurality of supporting-arms carried by and shiftable relative to the said hand or foot rail adapted to be brought into registration with and connected to said base or supporting members, in combination with means for temporarily locking the arms and base members together.

4. In a fire-escape, the combination with a plurality of base or supporting members adapted to be secured at desired points upon a building, a hand or foot rail, and a corresponding plurality of supporting-arms carried by and shiftable relative to the said hand or foot rail adapted to be brought into registration with and connected to said base or supporting members, said supporting-arms and the base or supporting members being separable in a vertical direction, in combination with means for temporarily locking the arms and base members together.

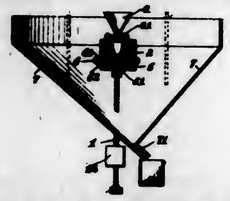
5. In a fire-escape, the combination with a plurality of base or supporting members adapted to be secured at desired points upon a building, a hand or foot rail, and a corresponding plurality of supporting-arms carried by and shiftable relative to the said hand or foot rail adapted to be brought into registration with and connected to said base or supporting members, in combination with means for temporarily locking the arms and base members together, and means for preventing turning of the rail when engaged by the hand or foot when in use.

6. In a fire-escape, the combination with a plurality of base or supporting members adapted to be secured at desired points upon a building, a hand or foot rail, and a corresponding plurality of supporting-arms carried by and shiftable relative to the said hand or foot rail adapted to be brought into registration with and connected to said base or supporting members, said supporting-arms and the base or supporting members being separable in a vertical direction, in combination with means for temporarily locking the arm and base members together, and means for preventing turning of the rail when engaged by the hand or foot when in use.

7. In a fire-escape, the combination with a plurality of base or supporting members adapted to be secured at desired points upon a building, a hand or foot rail, and a corresponding plurality of supporting-arms carried by and shiftable relative to the said hand or foot rail adapted to be brought into registration with and connected to said base or supporting members, in combination with means for preventing turning movement of the rail while engaged by the hand or foot when in use.

8. In a fire-escape, the combination with a plurality of base or supporting members adapted to be secured at desired points upon a building, a hand or foot rail, and a corresponding plurality of supporting-arms carried by and shiftable relative to the said hand or foot rail adapted to be brought into registration with and connected to said base or supporting members, said supporting-arms and the base or supporting members being separable in a vertical direction, in combination with means for preventing turning movement of the rail while engaged by the hand or foot when in use.

809,671. SHOT-MAKING MACHINE. PERCY F. COWING, New York, N. Y. Filed June 26, 1905. Serial No. 267,266.



Claim.—1. In a machine for converting molten metal into small solid particles, an approximately cylindric rotatable vessel having a peripheral emission-aperture so restricted in size as substantially to emit only small particles of metal, said aperture being located near the open end of said vessel and at approximately its greatest diameter.

2. In a machine for converting molten metal into small solid particles, an approximately cylindric vessel rotatable on a vertical axis and having a peripheral emission-aperture so restricted in size as substantially to emit only small particles of metal, said aperture being located near the open end of said vessel and at approximately its greatest diameter.

3. In a machine for converting molten metal into small solid particles, an approximately cylindric rotatable vessel having its wall pierced by a plurality of emission-apertures so restricted in size as substantially to emit only small particles of metal, said apertures being located near the open end of said vessel and at approximately its greatest diameter.

4. In a machine for converting molten metal into small solid particles, an approximately cylindric rotatable vessel having an open mouth and a peripheral emission-aperture so restricted in size as substantially to emit only small particles of metal, said aperture being located below said mouth, and means for feeding a supply of metal into said mouth.

5. In a machine for converting molten metal into small solid particles, an approximately cylindric rotatable vessel having a peripheral emission-aperture so restricted in size as substantially to emit only small particles of metal, said aperture being located near the open end of said vessel and at approximately its greatest diameter, and means for maintaining the metal in said vessel in a molten condition.

6. In a machine for converting molten metal into small solid particles, an approximately cylindric rotatable vessel having a peripheral emission-aperture so restricted in size as substantially to emit only small particles of metal, said aperture being located near the open end of said vessel and at approximately its greatest diameter, a burner for heating the exterior of said vessel, and a non-conducting jacket surrounding said vessel and spaced away therefrom for holding the heated products of combustion in contact therewith.

7. In a machine for converting molten metal into small solid particles, an approximately cylindric rotatable vessel having a peripheral emission-aperture so restricted in size as substantially to emit only small particles of metal, said aperture being located near the open end of said vessel and at approximately its greatest diameter, and a baffle-wall so located with relation to said emission-aperture as that the particles of metal escaping from said aperture will strike against said baffle before chilling.

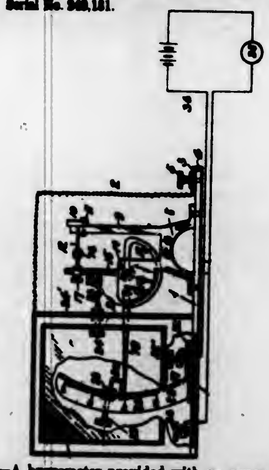
8. In a machine for converting molten metal into small solid particles, a rotary vessel having a constricted emission-aperture near its open end, in combination with a baffle suitably supported in said vessel and spaced away from the inner wall of said vessel.

9. In a shot-making machine, a rotary vessel having a contracted mouth and constricted peripheral emission-apertures, in combination with a baffle suitably supported in said vessel and providing an annular space between its periphery and the inner wall of said vessel.

10. In a shot-making machine, a rotary vessel having a contracted mouth and constricted peripheral emission-apertures, in combination with an annular baffle having a central opening and a peripheral diameter slightly less than the interior diameter of the vessel, and means for supporting said baffle within said vessel.

11. In a shot-making machine, a rotary vessel, a cap secured on said vessel and having a contracted mouth and a baffle having an annular portion of less diameter than the interior of said vessel, and upwardly-extending arms having outturned portions for fitting between the upper edge of said vessel and said cap.

809,672. AUTOMATIC INDICATING AND REGULATING HYGROMETER. STUART W. CRAMER, Charlotte, N. C. Filed Jan. 9, 1905. Serial No. 240,181.



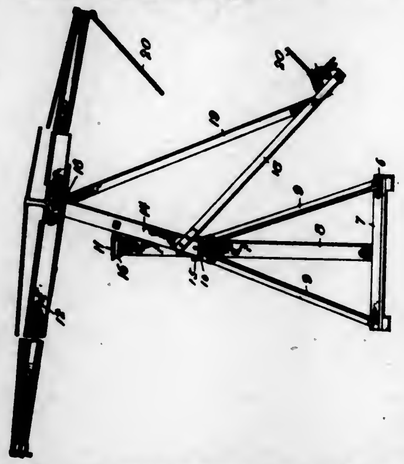
Claim.—A hygrometer provided with an expansible and contractible member, a shaft, an arm on the shaft connected to said member, a crank-arm secured to said shaft, a needle pivotally supported and connected to the crank-arm beyond its pivotal support, a tongue for making contact therewith, and a graduated scale; in combination with an electromagnet for operating a valve, a source of electrical energy, and electrical connections between the needle of the hygrometer, the magnet, and said source of electrical energy.

809,673. CAN-OPENER. JAMES W. DAVIS, Alto, Tex., assignor of one-half to Marshall B. McBee, Alto, Tex. Filed June 13, 1905. Serial No. 265,004.

Claim.—1. A base provided with a standard having a laterally-extending head, a cutting-blade fixed to said head relative to a can, a supporting-arm carried by said standard, a screw mounted upon said arm, and a can-support secured to the upper end of said screw to rotate therewith and move the can into cutting relation with said blade.

2. A base provided with a standard having a laterally-extending head, a cutting-blade fixed to said head relative to a can, a supporting-arm carried by said standard, a screw mounted upon said arm, a can-support secured to the upper end of said screw to rotate therewith and move the can into cutting relation with said blade, a centering-pin carried by the head in alinement with said screw, and means for adjusting said cutting-blade relative to said pin.

809,674. CRANE. WILLIAM B. HOSKINS, Madison Mills, Ohio. Filed Mar. 14, 1905. Serial No. 249,805.



Claim.—1. In a crane, in combination, a post, a rotatable frame mounted on the post and having uprights inclined backwardly from the perpendicular, a boom fulcrumed on top of said uprights, and a winch carried by the frame and having its rope connected to the boom.

2. In a crane, in combination, a post having upper and lower bearings, a frame rotatably supported on said bearings and having uprights extending above the top of the post and inclined backwardly from the perpendicular, a boom fulcrumed on top of the uprights, and a winch carried by the frame and connected to the boom.

809,675. TYPE-WRITING MACHINE. JACOB FRIEDL, New York, N. Y., assignor to Union Typewriter Company, Jersey City, N. J., a Corporation of New Jersey. Filed Apr. 5, 1904. Serial No. 201,777.

Claim.—1. In a type-writing machine, the combination with a pivotally-mounted type-bar, of a type-bar hanger, and means, mounted in the hanger and independently movable therein, for preventing longitudinal movement of the bar at the printing moment.

2. In a type-writing machine, the combination with a pivotally-mounted type-bar, of a type-bar hanger, and means on the type-bar and on the hanger for preventing longitudinal movement of the bar at the printing moment, the means on the hanger being independently movable.

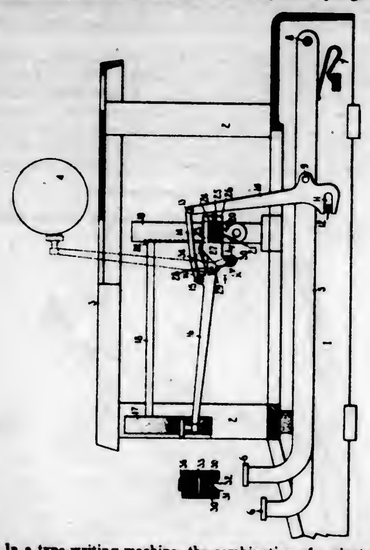
3. In a type-writing machine, the combination of a pivotally-mounted type-bar having a catch and a type-bar hanger provided with a rotary cooperating device to be engaged by said catch.

4. In a type-writing machine, the combination of a pivotally-mounted type-bar, a catch on said bar in rear of said pivot, a type-bar hanger, and a rotary step on said hanger to cooperate with said catch.

5. In a type-writing machine, the combination of a pivotally-mounted type-bar provided with a catch V-shaped in cross-section, and a type-bar hanger provided with a V-shaped step to cooperate with said catch.

6. In a type-writing machine, the combination of a pivotally-

mounted type-bar provided with a rearwardly-extending arm terminating in a catch that is V-shaped in cross-section, and a type-bar hanger provided with a coöperating device having a V-shaped groove.



7. In a type-writing machine, the combination of a pivotally-mounted type-bar having a rearwardly-extending hook-shaped arm, and a type-bar hanger having a coöperating roll provided with a V-shaped groove.

8. In a type-writing machine, the combination of a pivotally-mounted type-bar having a rearwardly-extending hook-shaped arm, a type-bar hanger provided with downwardly-extending supporting portions, and an independently-movable coöperating stop mounted therein and adapted to be engaged by said hook-shaped arm to prevent the bar from moving lengthwise.

9. In a type-writing machine, the combination of a type-bar, a hanger, a guide in the hanger, said guide being independently movable and coöperating with the type-bar to control it longitudinally.

10. In a type-writing machine, the combination of a type-bar, a hanger, and a pivotally-mounted guide in the hanger and coöperating with the type-bar to guide it longitudinally and laterally.

11. In a type-writing machine, the combination of a type-bar and an individual longitudinal guide for the bar adapted to be moved thereby and to coöperate therewith at and near the printing-point.

12. In a type-writing machine, the combination of a type-bar and an individual longitudinal and lateral guide for the bar adapted to be moved thereby and to coöperate therewith at and near the printing-point.

13. In a type-writing machine, the combination of a type-bar, a hanger, and a guide pivotally mounted in the hanger and adapted to coöperate with the type-bar, at and near the printing-point, to guide it longitudinally.

14. In a type-writing machine, the combination of a type-bar, a hanger, and a guide pivotally mounted in the hanger and adapted to coöperate with the type-bar, at and near the printing-point, to guide it longitudinally and laterally.

15. In a type-writing machine, the combination of a rotary longitudinal type-bar guide and a part coacting therewith, the two being brought into coöperation by the movement downward from normal position of one of the coacting parts.

16. In a type-writing machine, the combination of a rotary longitudinal and lateral type-bar guide and a part coacting therewith the two being brought into coöperation by the movement downward from normal position of one of the coacting parts.

17. In a front-strike type-writing machine, a type-bar having a portion normally projecting rearwardly from its pivot and adapted to coact with a rotary longitudinal type-bar guide below the pivot.

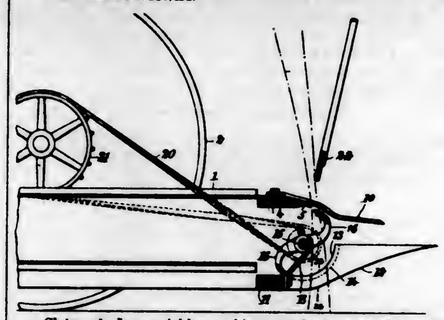
18. In a front-strike type-writing machine, a type-bar having a portion normally projecting rearwardly from its pivot and adapted to coact with a rotary longitudinal and lateral type-bar guide below the pivot.

19. In a type-writing machine, a hanger having a longitudinal type-bar guide pivotally mounted therein.

20. In a type-writing machine, a hanger having a longitudinal and lateral type-bar guide pivotally mounted therein.

21. In a type-writing machine, a type-bar having a beveled portion adapted to coöperate with a grooved roller to guide the type-bar longitudinally and laterally.

809,676. SICKLE. PEARL B. FLETCHER, Ridge, Oreg., assignor of one-half to Kenneth George Warner, Pendleton, Oreg. Filed Apr. 26, 1905. Serial No. 257,491.



Claim.—1. In a sickle-machine, a wheel-mounted draper, spaced guides extending downward and forward at an incline at the forward end of the draper, a sickle-blade arranged at the forward end of the draper, the said guides being tapered at the sides, lower guides alternating with the first-named guides, a shaft, and pressers mounted on said shaft and operating between the upper and lower guides.

2. In a sickle mechanism, a wheel-mounted draper, a bar extended across the forward end thereof, a sickle-blade mounted on the bar, guides extended at a forward and downward incline from said bar, the said guides being tapered at the sides, a bottom cross-bar, guides extended forward from said bottom cross-bar and alternating with the first-named guides, the said lower guides being curved and channeled at their inner ends, a shaft, pressers consisting of oppositely-extended arms mounted on said shaft and having broadened ends and adapted to pass through said channels of the lower guides, the said broadened ends being concaved, and means operated by a forward movement of the machine for rotating the shaft.

3. In a sickle-machine, a wheel-mounted draper, a thin blade arranged at the forward end of the draper, guide-fingers extended forward from said blade and tapered at the opposite sides, lower guide-fingers, a shaft, pressers mounted on said shaft, each consisting of oppositely-extended curved arms having broadened concaved ends, and guard-plates extended between the pressers and covering the front portion of the shaft.

4. In a sickle-machine, a wheel-mounted draper, a blade arranged at the forward end of the draper, guide-fingers extended forward from said blade, lower guides alternating with the first-named guides, and a presser coacting with the blade.

5. In a sickle-machine, the lower guides having their under sides curved upward and forward and their inner ends at the upper side curved upward and forward and channeled, and rotary presser-arms movable through said channels.

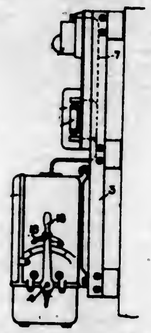
6. In a sickle-machine, the combination with a blade and guide-fingers, of a rotary shaft, and oppositely-curved presser-arms arranged on said shaft, the ends of said arms being concaved.

809,677. STARTING-COMPENSATOR FOR ALTERNATING-CURRENT MOTORS. EDWARD P. CUMMINGS, Schenectady, N. Y., assignor to General Electric Company, a Corporation of New York. Filed June 24, 1904. Serial No. 213,941.

Claim.—1. The combination with a compensator for starting an alternating-current motor, of a plurality of fuses, and means for connecting said compensator and fuses alternately with the motor-circuit.

2. The combination with a switch having contact-segments, of a compensator having its coils connected to fingers coöperating with said segments, and fuses connected to a second set of fingers adapted to make contact with said segments.

3. In combination, a switch having contact-segments and movable into a neutral position and into two operative positions, one at each side of said neutral position, two sets of contact-fingers one on each side of said segments, compensator-coils connected to one set and fuses connected to the other set, said segments engaging one set of said fingers when the switch is in one operative position, and engaging the other set of said fingers when the switch is in the other operative position.



4. The combination with a switch having contact-segments alternately connected with line-terminals and motor-terminals, of two sets of coöperating fingers, compensator-coils connected with one set, and fuses connected with the other set and with the line-terminals, the latter set of fingers coöperating only with the segments connected with the motor-terminals.

5. The combination with an alternating-current motor, of a plurality of fuses, a switch for connecting said fuses respectively in the legs of the circuit, and a motor in series with one of said fuses.

6. The combination with a compensator, of a plurality of fuses, a switch for connecting the compensator and fuses alternately with the terminals of an alternating-current motor, and means for compelling the compensator to be so connected before the fuses are.

7. The combination with a compensator, of a switch movable both ways from a neutral position, and a pivoted latch normally preventing said switch from being moved in one direction.

8. The combination with a motor-starting compensator, of a switch movable one way from a neutral position to a starting position and the other way to a running position, a switch-handle having a lug, and a pivoted latch engaging therewith and provided with a shoulder and an inclined surface adjacent thereto.

9. The combination with a circuit-controlling device having a handle movable both ways from a neutral position, and provided with a lug, of a pivoted latch engaging said lug by gravity and having on its under side a shoulder and a double incline, whereby when the lug is under the incline, a quick movement of the handle will throw the latch high enough to permit the lug to pass by the shoulder before the latch can fall.

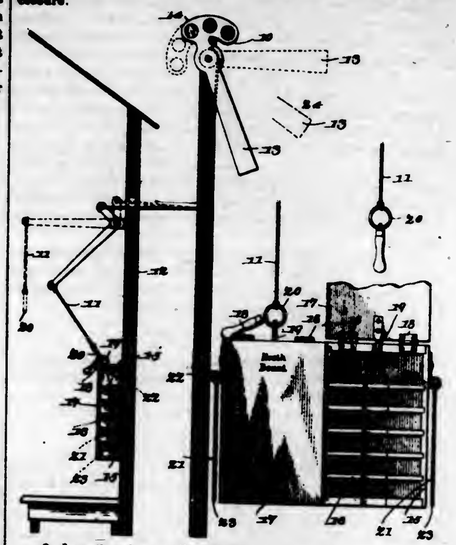
10. The combination with a handle movable both ways from a given position, of a lug, and a pivoted latch engaging said lug by gravity and having on its under side a shoulder and a double incline adjacent thereto, said lug and latch being relatively movable lengthwise of said latch.

11. In combination, a motor, a source of alternating current, compensator-coils, fuses, and means for connecting said motor to said source alternately through said coils and said fuses.

12. In combination, a motor, a source of alternating current, compensator-coils, fuses, and means for connecting said motor to said source alternately through said coils and said fuses, said means comprising a movable switch member and two sets of contact-fingers, one set connected to the compensator-coils and the other to the fuses.

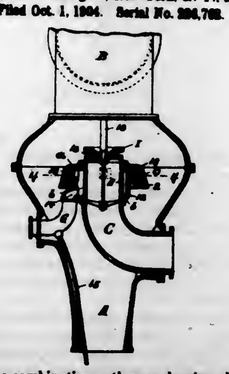
809,678. SEMAPHORE-SIGNAL ATTACHMENT. CHARLES H. GILL, Litchfield, Ill. Filed Feb. 1, 1905. Serial No. 243,705.

Claim.—1. In a signal-controlling device, a receptacle, a closure connected for swinging upwardly from said receptacle, a hook attached to said closure rearwardly of its connected end and disposed with its open side toward the free end of the same, a movable signal member, means for actuating said signal member and coupling means between said signal-actuating means and said hook, whereby the weight of said closure maintains the signal member in one position and automatically releasable by the opening of said closure.



2. In a signal-controlling device, a receptacle, a closure connected for swinging upwardly from said receptacle, a hook attached to said closure rearwardly of its connected end and disposed with its open side toward the free end of the same, a semaphore-signal arm swinging from one end, means for actuating said arm, and coupling means between said signal-actuating means and said hook, whereby the weight of said closure maintains said semaphore-arm in one position and automatically releasable by the opening of said closure.

809,679. CONDENSER. JOHN F. GRACE, New York, N. Y., assignor to Henry R. Worthington, New York, N. Y., a Corporation of New Jersey. Filed Oct. 1, 1904. Serial No. 226,762.



Claim.—1. The combination with a condensing-chamber, of an air collector and cooler therein consisting of a bell opening downwardly, a casing forming an air-chamber within said bell, air-passages connecting the bell with the air-chamber and inclined forwardly in the direction of movement of the air, and an air-discharge pipe connected with said air-chamber.

2. The combination with a condensing-chamber, of an air collector and cooler therein consisting of a bell opening downwardly, a casing forming an air-chamber within said bell, air-passages connecting the bell with the air-chamber and inclined forwardly in the direction of movement of the air, projections on the inner side of the bell, and an air-discharge pipe connected with said air-chamber.

3. The combination with an injector condensing-chamber and its condensing-water pipe and spraying devices, of a casing through which the condensing water passes to the spraying devices, an air-

chamber within said casing having its inner side cooled by the condensing water, an air-collecting bell outside said chamber over which the water is sprayed, air-passages from said bell to said air-chamber inclined forwardly in the direction of movement of the air, and an air-discharge pipe connected with said air-chamber.

4. The combination with an injector condensing-chamber and its condensing-water pipe and spraying devices, of a casing through which the condensing water passes to the spraying devices, an air-chamber within said casing having its inner side cooled by the condensing water, an air-collecting bell outside said chamber over which the water is sprayed, air-passages from said bell to said air-chamber inclined forwardly in the direction of movement of the air, ribs on the inner side of said bell extending transversely to the movement of the air, and an air-discharge pipe connecting with said air-chamber.

5. The combination with the casing *b* having air-chamber *c*, an air-discharge pipe from said chamber, bell *a* inclosing said casing and having ribs 2, and passages through the casing connecting the bell and air-chamber, substantially as described.

809,680. METHOD OF MAKING PIPES OF ARTIFICIAL STONE. JOSEPH HALL, Cheltenham, England. Filed Oct. 5, 1903. Serial No. 176,947.

Claim.—1. A method of manufacturing a concrete pipe, said method consisting in molding a moist concrete mixture to shape by centrifugal force and simultaneously removing liquid therefrom, comprising the molded pipe, and afterward allowing it to set.

2. A method of manufacturing a concrete pipe, said method consisting in molding a moist concrete mixture to shape by centrifugal force and simultaneously removing liquid therefrom, subjecting the molded pipe to external and internal pressure, and allowing the resulting pipe to set.

3. The herein-described method of manufacturing a concrete pipe, said method consisting in molding a moist concrete mixture to shape by centrifugal force, simultaneously separating liquid therefrom, then subjecting the partly-finished pipe to radial inward pressure, and afterward allowing the pipe to set.

4. The herein-described method of manufacturing a concrete pipe, said method consisting in subjecting a liquid mass of concrete mixture to rotary motion and limiting its outward movement so as to cause it to assume the required tubular shape by centrifugal force, separating liquid from said mass during the rotary motion, compressing the partly-finished pipe externally while still rotating but at a slower speed, arresting the motion of said pipe, and allowing it to set.

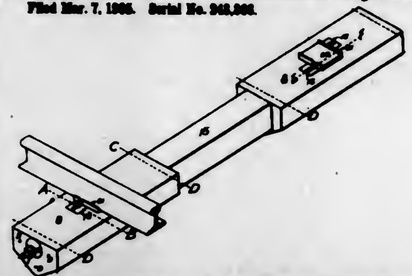
5. The herein-described method of manufacturing a concrete pipe, said method consisting in molding a liquid mass of concrete to a tubular shape by centrifugal force and simultaneously removing water therefrom also by centrifugal force, subjecting the partly-finished and dried pipe to external pressure while firmly supporting the inner surface thereof, and allowing said pipe to set.

809,681. STRAP-LOOP. HARRY HART, Milwaukee, Wis. Filed May 4, 1905. Serial No. 258,570.

Claim.—1. In a strap-loop, the combination of a strap member having a turned-under end, a loop-strap passed into the space between the turned-under end of the strap member and the main portion of said strap member, the ends of said loop-strap being carried over the strap member and brought together, a clasp arranged at the joint of the abutting ends of the loop-strap, said clasp provided at opposite edges with teeth or serrations, and at opposite ends with prongs, the toothed or serrated edges being bent around the edges of the loop-strap and thence beneath said strap and the teeth or serrations forced upwardly into the material of the strap, and the end prongs of the clasps being forced downwardly through the loop-strap and bent beneath the same, and means for securing the turned-over end of the strap member to the main portion of said strap member and for also securing the loop in the space therebetween.

2. In a device of the character described, the combination of a strap member with its end turned under, a loop-strap with its intermediate portion passing through the space between the turned-under end of the strap member and the main body thereof, fastening means passing through the main body of the strap member, the loop-strap and the turned-under end of the strap member, and a metal clasp joining the ends of the loop-strap, said clasp having integral end and side prongs the former passing through the loop-strap ends and clenched thereto and the latter passing around the loop-strap ends and clenched thereto.

809,682. RAILWAY-TIE. THOMAS R. HARLEY, Houghton, Mich. Filed Mar. 7, 1905. Serial No. 248,866.



Claim.—1. A railway-tie of plastic material, comprising rail-supporting blocks having opposite tapers on the under side, a center block, metal strips extended longitudinally through the several blocks, and metal strips arranged transversely in the bearing-blocks.

2. A railway-tie comprising bearing-blocks tapered on the bottom, a center block, a tie-rod extended through the several blocks, fastening devices on the ends of said rod, and metal strips extended longitudinally through the blocks.

3. A railway-tie of plastic material, comprising bearing-blocks, and metal bearings or casings casted in said blocks and adapted to receive wooden blocks the said blocks having downward and outward openings in line with said bearings.

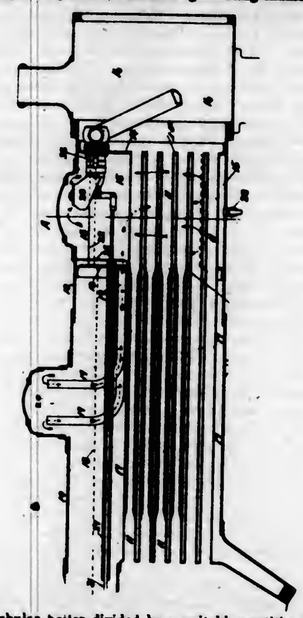
4. A railway-tie of plastic material, comprising bearing-blocks having openings extended vertically through them, metal bearings arranged in said openings, the inner surfaces of opposite walls of the bores being inclined inward and downward for a portion of the distance near the bottom, and metal strips extended longitudinally through the blocks.

5. A railway-tie of plastic material, comprising bearing-blocks having vertical openings, bearings arranged in said openings, channel-plates mounted on the blocks, and resilient plates arranged in the channel-plates.

6. A railway-tie consisting of plastic material and comprising bearing-blocks, a center block abutting at its ends with the bearing-blocks, the said several blocks having a longitudinal opening or bore, curved plates arranged in the bearing-blocks and extending over said bore near its ends, and a clamping-bar passing through said bore.

809,683. STEAM GENERATOR AND SUPERHEATER. FRANK A. HASBROUCK, Schenectady, N. Y. Filed Oct. 3, 1904. Serial No. 227,053.

Claim.—1. A tubular boiler divided by a suitable partition into two chambers, one being adapted to form a steam-generator and the other to act as a superheater and means to retard the transmission of heat from a plurality of the tubes to the generating-chamber.



2. A tubular boiler divided by a suitable partition into two chambers, one being adapted to form a steam-generator and the other to act as a superheater and screens carried by a plurality of the tubes in the generating-chamber to retard the transmission of heat from the tubes to the generating-chamber whereby a greater degree of heat is delivered to the superheater.

3. A tubular boiler divided by a suitable partition into two chambers, one being adapted to form a steam-generator and the other to act as a superheater and linings in a plurality of the tubes in the generating-chamber to retard the transmission of heat from the tubes to the generating-chamber whereby a greater degree of heat is delivered to the superheater.

4. A tubular boiler divided by a suitable partition into two chambers, one being adapted to form a steam-generator and the other to act as a superheater and short sections of tubing expanded in a plurality of the tubes in the generating-chamber to retard the transmission of heat from the tubes to the generating-chamber whereby a greater degree of heat is delivered to the superheater.

5. In a tubular boiler wherein steam is generated at one end of the boiler and superheated at the other end thereof, means interposed between the gases of combustion and the heating-surfaces of the generator to retard the transmission of heat to the generator.

6. A tubular boiler divided by a suitable partition into a generating and superheating chamber, with suitable steam connections, the tubes of the boiler being continuous and passing through both chambers, in combination with means interposed between the heating-surfaces of the generator-chamber and the gases of combustion to retard the transmission of heat to the generator.

7. The combination with a steam generator and superheater of a plurality of fire-tubes passing through the water-space of the generator and into the superheater, at least one of said fire-tubes being provided with means to retard or diminish the transmission of heat to the water in the generator.

8. The combination with a steam generator and superheater of a plurality of fire-tubes passing through the water-space of the generator and into the superheater, at least one of said fire-tubes being provided with a screen to retard or diminish the transmission of heat to the water in the generator, thereby enabling the gases of combustion passing through the fire-tubes to deliver to the superheater a higher degree of temperature.

9. The combination with a steam generator and superheater of a plurality of fire-tubes passing through the water-space of the generator and into the superheater, at least one of said fire-tubes being provided with a lining in a portion of the tube in the generating-chamber to retard or diminish the transmission of heat to the water in the generator, thereby enabling the gases of combustion passing through the fire-tubes to deliver to the superheater a higher degree of temperature.

10. The combination with a steam generator and superheater of a plurality of fire-tubes passing through the water-space of the generator and into the superheater, a plurality of said fire-tubes being provided with means to retard or diminish the transmission of heat to the water in the generator.

11. The combination with a steam generator and superheater of a plurality of fire-tubes passing through the water-space of the generator and into the superheater, a plurality of said fire-tubes being provided with a screen to retard or diminish the transmission of heat to the water in the generator, thereby enabling the gases of combustion passing through the fire-tubes to deliver to the superheater a higher degree of temperature.

12. The combination with a steam generator and superheater of a plurality of fire-tubes passing through the water-space of the generator and into the superheater, a plurality of said fire-tubes being provided with a lining in a portion of the tube in the generating-chamber to retard or diminish the transmission of heat to the water in the generator, thereby enabling the gases of combustion passing through the fire-tubes to deliver to the superheater a higher degree of temperature.

13. A tubular boiler divided by a suitable partition into two chambers, one being adapted to form a steam-generator and the other to act as a superheater, a baffle-plate arranged longitudinally of the superheater in a vertical plane, an open pipe leading from the generating-chamber to the portion of the superheater on one side of the baffle-plate and means to control the exit of steam from the superheater arranged on the other side of the baffle-plate.

14. A tubular boiler divided by a suitable partition into two chambers, one being adapted to form a steam-generator and the other to act as a superheater, a pair of baffle-plates arranged longitudinally of the superheater, open pipes leading from the generating-chamber to the portion of the superheater between the plates and the shell of the superheater and means to control the exit of steam arranged between the baffle-plates.

15. A tubular boiler divided by a suitable partition into two chambers, one being adapted to form a steam-generator and the other to act as a superheater, a baffle-plate located longitudinally of the superheater in a vertical plane, an open pipe leading from the generating-chamber to the portion of the superheater on one side of the baffle-plate, means to control the exit of steam from the superheater arranged within the superheater on the other side of the baffle-plate, said baffle-plate being arranged to suddenly change the direction of flow of the steam near the bottom of the superheater, thereby separating moisture or water carried by the steam from the steam, depositing same at the bottom of the superheater, and means for drawing off said collected moisture from the superheater.

16. A tubular boiler divided by a suitable partition into two chambers, one being adapted to form a steam-generator and the other to act as a superheater, a pair of baffle-plates located longitudinally of the superheater, open pipes leading from the generating-chamber to the portion of the superheater between the plates and the shell of the superheater, means to control the exit of steam arranged between the baffle-plates, said baffle-plates being arranged to suddenly change the direction of flow of the steam, thereby separating moisture or water carried by the steam from the steam, and means for drawing off said collected moisture from the superheater.

17. A tubular boiler divided by a suitable partition into two chambers, one being adapted to form a steam-generator and the other to act as a superheater, a throttle located in the superheating-chamber a tube extending from the superheating-chamber to the back end of boiler through which the operating-rod of the throttle is adapted to pass.

18. A tubular boiler divided by a suitable partition into two chambers, one being adapted to form a steam-generator and the other to act as a superheater, a pair of baffle-plates arranged in the superheater, open pipes leading from the generating-chamber to the portion of the superheater between the plates and the shell of the superheater and means to control the exit of steam arranged between the baffle-plates.

19. The combination with a steam-generator of a superheater, a pair of baffle-plates arranged in the superheater, open pipes leading from the boiler to the portion of the superheater between the plates

and the shell of the superheater and means to control the exit of

Claim.—1. A gage comprising a base-rule, a vertical rule slid- and shanks projecting from the blades and fastened to the

and the shell of the superheater and means to control the exit of steam arranged between the baffle-plates.

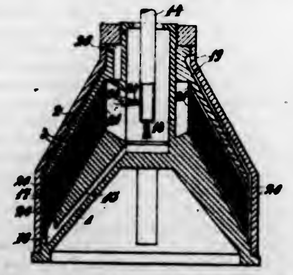
20. The combination with a steam-generator, of a superheater, a pair of baffle-plates arranged longitudinally of the superheater, open pipes leading from the generating-chamber to the portion of the superheater between the plates and the shell of the superheater and means to control the exit of steam arranged between the baffle-plates.

809,684. CURTAIN-STRETCHER. FREDERICK M. HAYNES, Buffalo, N. Y. Filed Jan. 26, 1905. Serial No. 243,697.

Claim.—1. A curtain-stretcher comprising a divided bar the sections of which are connected by a joint consisting of reduced portions or tongues arranged on the inner opposing ends of said sections, each tongue having oblique shoulders at its inner and outer ends which converge toward the inner side of the respective section, said tongues overlapping each other and each bearing with its oblique outer shoulder against the oblique inner shoulder of the other tongue, and means for detachably connecting said tongues, substantially as set forth.

2. A curtain-stretcher comprising a divided bar the sections of which are connected by a joint consisting of reduced portions or tongues arranged on the inner opposing ends of said sections, each tongue having oblique shoulders at its inner and outer ends which converge toward the inner side of the respective section, each tongue having its inner shoulder undercut on a bevel and its outer shoulder beveled correspondingly and said tongues overlapping each other and each engaging its oblique beveled outer shoulder with the oblique undercut inner shoulder of the other tongue, and means for detachably connecting said tongues, substantially as set forth.

809,685. LINER FOR CENTRIFUGAL LIQUID-SEPARATORS. CARL D. HELLSTRÖM, Nyfors, Sweden. Filed June 9, 1905. Serial No. 264,468.



Claim.—1. A liner for centrifugal liquid-separators consisting of a plurality of superposed and spaced funnel-like plates, provided with apertures 17 near their outer periphery, with a rib 20 extending along the same and situated outside the said apertures, and with ribs 4 extending from the said periphery inward toward the center of the plate, causing the full milk led to the periphery of the liner to rise through the apertures and spread in all the spaces.

2. The combination of a liner for centrifugal liquid-separators, consisting of a plurality of superposed and spaced funnel-like plates provided with apertures 17 near the outer periphery, with a rib 20 extending along the same and formed by the plate edge being bent upward, and further with ribs 4 extending from the said rib, inward toward the center of the plate, and of a central feeding-chamber communicating through bottom channels 15 with the said apertures of the liner, situated one above the other, for the introducing of the full milk into all the spaces at the periphery of the liner, substantially as described.

3. The combination of a liner for centrifugal liquid-separators, which liner consists of superposed and spaced funnels, provided near the periphery with apertures 17 and with a rib 20, extending along the periphery of the funnel, and with ribs 4 extending from the said rib inward toward the center of the funnel, and of a central feeding-chamber, communicating through bottom channels 15 with the said apertures 17 and an inlet-tube 14, which, in addition to an aperture leading the full milk to the bottom channels 15, has a side opening 24, leading a part of the full milk into the spaces between the funnels, at the inner edges of same.

4. A liner for centrifugal liquid-separators consisting of superposed and spaced funnel-shaped plates, provided near the periphery with apertures 17, leading the full milk to the spaces between the funnels, and with ribs 20, 21 formed by the outer and inner edges respectively of the plate being bent upward, and with ribs 4 extending from the periphery of the plate toward the center of same and forward in the rotary direction, and further with apertures 22 in the inner edge rib 21, through which the cream can leave the space between the plates, and with apertures 23 in the said rib 21, through which a part of the full milk is led from the center of the liner into the said space, substantially as described and for the purpose set forth.

5. A liner for centrifugal liquid-separators consisting of superposed and spaced funnel-like plates, provided near the periphery with apertures 17, with a rib 20 extending along the periphery of the plate and formed by the edge being bent upward, with ribs 4, extending from the said rib 20 inward toward the center of the plate, and with ribs 11 extending along the outer edge of the plate at some distance from the same, a passage being provided between the said rib 11 and the opposite transversal rib 4 and also between the rib 11 and the next plate, so that the light part of the liquid can pass along the surface of said plate, substantially as described and for the purpose set forth.

6. A liner for centrifugal liquid-separators consisting of superposed, spaced funnel-shaped plates, provided with apertures 17, leading the full milk to the spaces between the plates, and with ribs 4 which owing to their radial position on the plate and in combination with ribs 20, 21, formed by the inner and outer edges of the plate being bent upward, divide the space into sections, each provided with an inlet-opening 17 and an outlet-opening 18, and further with ribs 8, 9 situated nearer the inner edge of the plate in comparison with the said ribs 4 and forming a continuation of the same after an interval 10, substantially as described and for the purpose set forth.

7. In liner for centrifugal liquid-separators consisting of superposed, spaced funnel-like plates provided at the periphery with apertures 17 for the introducing of the full milk, and near the periphery with apertures 18 forming outlet-openings for the blue milk, the said apertures 17 and 18 being provided inside a rib extending along the periphery of the plate and formed by the edge being bent upward, and further with ribs 4 and 8, 9 extending in an oblique direction to the radius of the plate between the outer edge and the inner edge of the plate but leaving a passage 10 for the light part of the liquid, so that it can pass to the outlet-opening 22 at the inner edge of the plate.

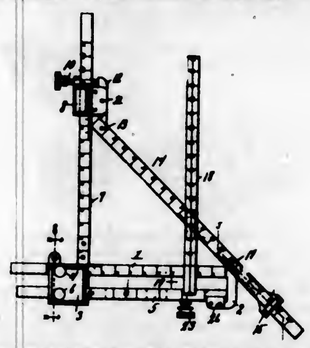
8. A liner for centrifugal liquid-separators consisting of superposed spaced funnel-like plates provided with ribs concentric with or substantially concentric with the center of the funnel, some ones 20, 11 of the said ribs being situated near the outer edge of the plate and other ones 9, 21 near the inner edge of the same, and with apertures 17 near the outer edge for the introducing of the full milk into the spaces between the plates, and with apertures 18 forming outlet-openings for the blue milk, and further with ribs 4, and 8, 9 which form an angle with the said ribs and divide the space into sections, each having an inlet-opening 17 and an outlet-opening 18 substantially as described and for the purpose set forth.

9. A liner for centrifugal liquid-separators consisting of superposed spaced funnel-like plates provided at their inner and outer edges with ribs concentric or substantially concentric with the center of the funnels, inlet-openings 17 and outlet-openings 18 for the full milk and the blue milk respectively, outlet-openings 22 for the cream, ribs 4, guiding the full milk along the plate-surface inward toward the center of the plate, and angular ribs 8, 9 forming a further guide for the cream toward the outlet-opening 22, substantially as described and for the purpose set forth.

10. A liner for centrifugal liquid-separators consisting of superposed, spaced funnel-like plates, provided near their periphery with inlet-openings for the full milk and outlet-openings for the blue milk, and on the upper side with ribs, extending from the periphery of the plate inward toward the center of the plate in an oblique direction and causing the full milk to spread on the upper side of the plate or funnel, and on their under side with ribs 11, guiding the blue milk separated from the full milk and passing outward toward the outlet-opening 18, substantially as described and for the purpose set forth.

809,686. RAFTER-CAGE. EDWIN H. HOOVER, Pontiac, Mich. Filed Oct. 20, 1904. Serial No. 229,230.

Claim.—1. A gage comprising a base-rule, a vertical rule slidably mounted on the base-rule, an angle-rule, means for pivotally and slidably connecting the angle-rule to the vertical rule, said angle-rule lying in engagement with the end of the base-rule.



2. A gage comprising a base-rule, a vertical rule longitudinally movable on the base-rule, a hypotenuse-rule longitudinally movable at each end with respect to the vertical rule and to the base-rule respectively, and a rule slidable upon the base-rule and intersecting the line of the hypotenuse-rule.

3. A gage comprising a base-rule, a vertical rule, a hypotenuse-rule, a spacing-rule parallel with the base-rule, and a rule movable longitudinally of the base and spacing rule and intersecting the line of the hypotenuse-rule.

4. A gage comprising a base-rule, a block slidable thereon, a rule mounted on said block extending at right angles to the base-rule, a movable head upon said last-mentioned rule, a hypotenuse-rule pivoted at its upper end to said head and having a slidable engagement at its lower end with the base-rule.

5. A gage comprising rule members describing a right angle, movably joined at the point of union, a hypotenuse-rule, means for slidably and pivotally connecting one end of the hypotenuse-rule to one of said rule members, and means for affording a longitudinally-movable engagement between the opposite end of the hypotenuse-rule and the other of said rule members.

6. A gage comprising rule members describing a right angle, movably joined at the point of union, a hypotenuse-rule, means for slidably and pivotally connecting one end of the hypotenuse-rule to one of said rule members and means for affording a longitudinally-movable engagement between the opposite end of the hypotenuse-rule and the other of said rule members, and an auxiliary rule member movably mounted upon one of the first-mentioned rule members and intersecting the hypotenuse-rule.

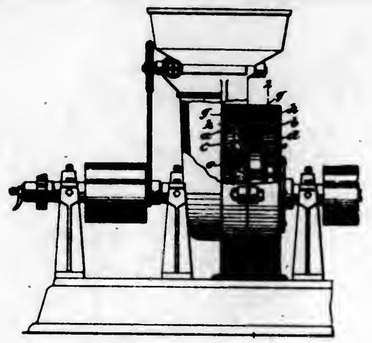
7. A gage comprising a base-rule, a block movable thereon, a spacing-rule movable in said block and parallel with said base-rule, a rule member rigidly mounted on said block and extending at right angles to the base-rule, a hypotenuse-rule crossing between the ends of said rule members, and an auxiliary rule mounted to slide upon the base-rule and spacing-rule and intersecting the hypotenuse-rule.

8. A gage comprising a base-rule, a block movable on the base-rule and attachable thereto, a vertical rule fixed in said block and extending at right angles to the base-rule, a head movable upon said vertical rule, a pivoted arm on said head, a screw engaging one end of said arm, a hypotenuse-rule pivoted at its upper end to the other end of said arm, and a guide for lower end of said hypotenuse-rule affording a longitudinally-movable engagement thereof with the end of the base-rule.

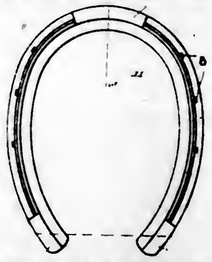
9. A gage comprising a base-rule, a vertical rule movably mounted on the base-rule, a head slidably mounted on said vertical rule, a pivoted arm on said head, means for actuating said arm, a hypotenuse-rule pivoted at its upper end to said pivoted arm, an arm pivoted to the end of the base-rule having a guide at the end thereof, the lower end of the hypotenuse-rule passing through said guide.

809,687. MILL. HENRY A. HOWARD, Sherburne, N. Y. Filed Jan. 5, 1903. Serial No. 238,754.

Claim.—A grinding-mill having a curb or casing, opposed grinding disks or heads located therein and having their peripheries spaced from the facing of the curb, and clearing members comprising U-shaped blades embracing the flanged peripheries of the disks, and shanks projecting from the blades and fastened to the outer faces of the grinding-heads one arm of said U-shaped blade lying outward from the periphery of the grinding-head between the same and the facing of the curb, for the purpose specified.



809,688. HORSESHOE. JAMES HOWARD, Millvale, Pa., assignor of one-fourth to J. Irving Allshouse, Stanton, Pa., and one-fourth to W. N. Barkhouse, Baxter, Pa. Filed June 2, 1905. Serial No. 263,462.



Claim.—1. A horseshoe of the character described formed of three strips of metal rolled to form a substantially T-shaped strip of metal, the vertical portion of said strip of metal having a sharpened edge, substantially as described.

2. A horseshoe of the character described consisting of stripes of iron and a strip of steel rolled to form a substantially T-shaped strip having a sharpened edge, substantially as described.

809,689. EXCAVATING-MACHINE. ALFRED F. HUBER, Chicago, Ill. Filed July 3, 1905. Serial No. 268,067.

Claim.—1. In an excavating-machine, a frame or platform; a crane; a bucket-arm having a gear-rack thereon; a pinion in mesh with said gear-rack; a sprocket-wheel mounted on the axis of said pinion, a winding-drum; a rope, cable or the like having one end wound upon said drum connected with said bucket-arm to move the latter in the arc of a circle about said pinion, said rope or cable passing over a series of pulleys one of which has a driving sprocket-wheel portion for driving said first-mentioned sprocket-wheel; a sprocket-chain which connects said sprocket-wheels, whereby simultaneous rotary and longitudinal movement may be imparted to said bucket-arm, and a clutch mechanism for throwing the pinion meshing with said gear-rack in and out of operative connection with said drum and cable.

2. In an excavating-machine, the combination with a pivotally-movable crane having a bucket-arm and bucket mounted thereon, of a winding-drum; a rope and series of pulleys connecting said bucket and drum for raising and lowering the former by the latter, and a mechanism driven by said rope for imparting longitudinal movement to said bucket-arm.

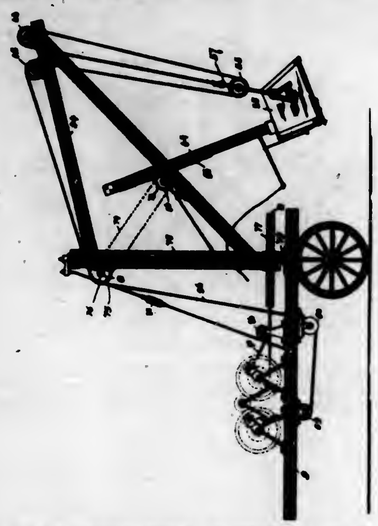
3. In an excavating-machine, a crane; a revoluble and longitudinally movable bucket-arm; a reel and cable arranged to raise and lower said arm, and a mechanism driven by said cable for moving said arm longitudinally; a shaft upon which said reel is revolubly mounted, clutch members upon, respectively, said reel and shaft and at opposite ends thereof, the clutch members at one end of the

reel and shaft being arranged to rotate in one direction and the

to clamp a pen therebetween and the said sleeve, a finger-block hav-

of the boats carried by said carrier elements, substantially as de-

reel and shaft being arranged to rotate in one direction and the clutch members at the opposite end of the reel and shaft arranged to rotate in the opposite direction, and means for shifting said shaft and reel relatively to each other, whereby the motion of the reel may be reversed, as specified.



4. In an excavating-machine, the combination with a crane, of a bucket-arm revolubly and longitudinally movable upon said crane, a reel and cable arrangement for raising and lowering said arm in a circular arc; a mechanism driven by said cable for simultaneously moving said arm longitudinally; a driving-shaft; a pair of driven shafts arranged to be rotated by said driving-shaft in the same direction; sleeve-shafts or reels mounted on said driven shafts for longitudinal and rotary movements thereupon, said sleeve-shafts or reels having female clutch members at opposite ends thereof, and said driven shafts having male clutch members adapted to coöperate with said female clutch members, the male clutch member at one end of each of said driven shafts being arranged to be rotated by said driving-shaft in one direction and the male clutch members at the opposite ends of said driven shafts being arranged to be rotated by said driving-shaft in the opposite direction; means for shifting said sleeve-shafts or reels from one set of clutch members to the other to reverse the direction of motion, and means whereby one of said reels is caused to rotate said crane while the other reel operates said bucket-arm to move same revolubly and longitudinally

5. In an excavating-machine; a platform; a crane revolubly mounted thereupon; means for adjusting the axis of rotation of said crane; a bucket-arm having a bucket thereon; a reel or drum 25 and a cable arranged to raise and lower said bucket-arm in a circular arc, a mechanism driven by said cable adapted to, simultaneously with the raising and lowering of said bucket-arm in a circular arc, move said arm longitudinally; said reel 25 having female clutch members 27 and 28 on opposite ends thereof; a shaft 13 upon which said reel is rotatively and longitudinally movable, said shaft having thereon male clutch members 19 and 20 adapted to coöperate with, respectively, said female clutch members 27 and 28; means whereby said shaft drives one of said female clutch members, when connected therewith, in one direction of rotation, while the same shaft is adapted to drive the other female clutch member in the opposite direction of rotation when connected with the latter member, a lever for shifting said female clutch members in and out of engagement with the respective male clutch members; a reel 26 similar to reel 25 and a shaft 14 similar to shaft 13, said reel 26 and shaft 14 having coöperating clutch members identical to, and relatively movable as, the clutch members for reel 25 and shaft 13, and means whereby said crane is revolved by said reel 26.

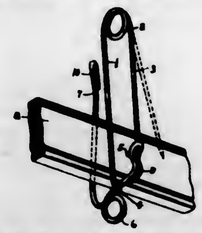
809,690. RAZOR-BLADE HOLDER. JAMES H. HUNT, Hamilton, Ohio. Filed May 16, 1905. Serial No. 260,696.

Claim.—1. A razor-blade holder, comprising body-plates having handle and jaw sections, the jaw-sections being adapted to receive a razor-blade between them, a confining-loop which is slid over the outer end portions of the jaw-sections of the said plates, and a wedge-block adapted to be introduced between opposing faces of the handle-sections of the plates.

3. A razor-blade holder, comprising upper and lower body-plates, each body-plate comprising a handle and a jaw-section, the opposing faces of the said body-plates being straight throughout their length but the outer faces of the jaw-sections of said plates being beveled downward in direction of their forward ends, a loop which is slid over the outer end portions of the said body-plates, engaging with the beveled surfaces of the jaw-sections of said plates, and a wedge-block which is introduced between the handle-sections of the plates when the loop 15 is in position thereon.

3. A razor-blade holder, consisting of an upper and a lower body-plate, each body-plate comprising a handle and a jaw section, the inner faces of the body-plates being straight throughout their length and the outer faces of the jaw-sections of the said plates being beveled from a point near the handle downward and outward, so that said body-plates are thinnest at their outer ends, a loop which receives the said body-plates at their inner ends and engages with the beveled surfaces thereof, and a wedge-block which is introduced between the handle-sections of the said body-plates, the wedge-block having its upper and lower faces curved at its side edges.

809,691. HORSE-BLANKET PIN. MERWIN L. JACOBY, Canton, Ohio. Filed June 9, 1905. Serial No. 264,491.



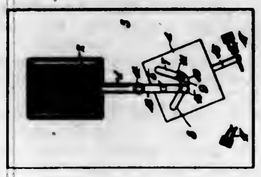
Claim.—As an improved article of manufacture, a horse-blanket pin constructed of a single piece of wire and comprising a shank, spring-coiled loops one located upon the shank and the other located at the base of a spring-shank and the spring-shank extended therefrom, a pin extended from the spring-coil formed upon the shank, a pin-holding guard-loop adapted to hold and guard the point of the pin, said loop consisting of two members, one continued from the second spring-coiled loop and the other member passing through said loop, all arranged substantially as and for the purpose specified.

809,692. PENHOLDER. OLE JOHNSON, Cedarhome, Wash. Filed Mar. 31, 1905. Serial No. 253,269.

Claim.—1. A penholder comprising a handle, a pen-receiving sleeve carried by the handle, said sleeve being provided with a longitudinal slot, a spring clamping member arranged to clamp a pen therebetween and said sleeve, a finger-block having grooves formed in its sides, said block being engaged in said slot and being provided with an inclined under face adapted to engage the said spring clamping member.

2. A penholder comprising a handle, a pen-receiving sleeve carried by the handle, said sleeve being provided with a longitudinal slot, a spring clamping member pivoted in said sleeve and arranged to clamp a pen therebetween and the said sleeve, a finger-block having grooves formed in its sides the said grooves being arranged to receive the sides of the said slot, said finger-block being provided with an inclined under face adapted to engage the said spring clamping member.

809,693. MECHANICAL MOVEMENT. GRAY W. JOHNSTON, New York, N. Y. Filed Mar. 27, 1905. Serial No. 252,244.



Claim.—1. The combination with a solenoid of a reciprocable driving member operated by said solenoid, a pivotally-mounted driven member capable of swinging movement transversely of said driving member, the pivot of the driven member being in line with the direction of movement of said driving member and said driving member being constrained to move in the line of said pivot, and the driven member being provided with angularly-arranged walls diverging from the apex formed at their meeting-point, to opposite sides of said pivot, and a connecting element pivoted to said driving member and dependent therefrom and carrying a projection adapted to ride upon and engage said walls, alternately, being shifted from one to the other by gravity together with the camming action of said walls upon successive movements of the driving member in the same direction.

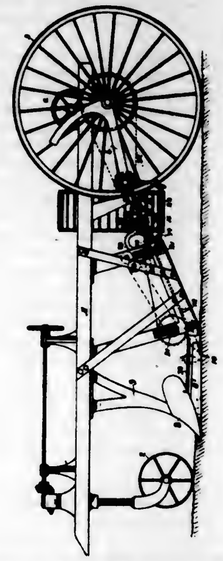
2. The combination with a reciprocable driving member, of a pivotally-mounted driven member capable of swinging movement transversely of said driving member, the line of reciprocation of said driving member always containing the pivot of the driven member, the said driven member being provided with a substantially V-shaped slot whose branches diverge to points on opposite sides of the pivot and whose central portion is enlarged, forming pockets on opposite sides of the apex formed at the intersection of the upper or inner walls of said branches, a connecting element pivoted to said driving member and carrying a projection which is movable in said slot, which seats itself in one or the other of said pockets by virtue of gravity and the camming action of said slots when said driving member is in retracted position, and which engages the walls of said slot, alternately, upon successive movements of said driving member in the same direction, and frictional means for retaining said driven member at the limit of its movement in each direction, whereby the driven member is moved in alternate directions upon each reciprocation of the driving member.

3. In a device of the class described, a support or frame, a solenoid disposed upon said frame, contacts also mounted on said frame, a member pivoted upon said frame to swing into engagement with said contacts alternately and having cam-surfaces thereupon, a core slidably mounted in said solenoid, a link pivoted to said core and having a part engaging said cam-surfaces, frictional means for holding the pivoted member in either of its extreme positions, whereby said pivoted link is cammed into engagement with alternate cam-surfaces upon the pivoted member at successive actuations of the core of the solenoid.

4. The combination of a reciprocating driving member, a guide therefor arranged to constrain the movement of said reciprocating member in a right line, a pivotally-mounted driven member capable of swinging movement transversely of said driving member, the pivot of the driven member being in line with the direction of movement of said driving member, and the driven member being provided with angularly-arranged walls diverging from the apex formed at their meeting-point, to opposite sides of said pivot, and a connecting element pivoted to said driving member and carrying a projection adapted to engage said walls, alternately, upon successive movements of the driving member in the same direction.

809,694. BEET-HARVESTER. CHARLES L. JOLLY, Salinas, Cal., assignor of one-third to Stansfield Sherwood, Salinas, Cal. Filed May 31, 1905. Serial No. 262,227.

Claim.—1. In a beet-harvester, the combination of endless traveling beet-carrier elements, and beet-top cutters disposed in the path of the beets carried by said carrier elements, substantially as described.



2. In a beet-harvester, the combination of means to uproot the beets, means to engage and carry the uprooted beets, and means to cut off the tops of the beets, to which top-cutting means the said carrying means convey the beets, substantially as described.

3. A beet-harvesting apparatus, consisting of a wheeled frame, a pair of plows supported therefrom with parallel adjacent landsides and moldboards to turn the earth outwardly from the row of beets, a blade extending between the rear ends of the landsides adapted to sever the tap-roots and lift the beets from the ground, carrying-belts for the beets and guide-rods between which the upper part of the beet passes and is transmitted to carrying-belts.

4. In a beet-harvesting apparatus, a wheeled frame, means for raising and lowering the frame upon its wheels and guiding the same, a pair of plows fixed to the frame having adjacent parallel landsides and moldboards adapted to turn the earth outwardly away from the row of beets, a cutting and lifting blade at the rear of the landsides and guides between which the beets are maintained upright as they pass rearwardly, a pair of endless traveling belts between which the beets are delivered from said guides, and a cutter revolving transversely to the line of travel and contiguous to the upper ends of the carrying-belts.

5. In an apparatus for harvesting beets, a wheeled frame with means for raising, lowering and steering, a pair of plows supported therefrom, with parallel adjacent landsides and outwardly-turning moldboards, a lifting and cutting blade at the rear of the landsides and guides between which the beets are transmitted rearwardly, a pair of endless traveling belts between which the beets are delivered, said belts having their transverse bars concaved toward each other to retain the beets in a central position, and elastic arms fixed with relation to the traveling belts and between which the beets are carried by the belt.

6. In a beet-harvesting apparatus, a wheeled and vertically-adjustable frame, with plows and lifting-blade by which the beets are extricated from the ground, adjustable endless belts between which the beets are delivered and by which they are carried upwardly and rearwardly, a cutter with means for intermittently rotating it transversely to the line of travel of the beets, and a stop against which each beet strikes as it arrives at the upper end of the carrying-belts, said stop acting to engage the mechanism by which the cutter is revolved.

7. In an apparatus for harvesting beets, plows, lifters and carrying-belts by which the beets are transmitted to the point where the tops are to be severed, a shaft having one member of a clutch fixed to and revolvable therewith, a second member turning loosely upon the shaft and carrying a cutter which is revolvable transversely to the line

of travel of the beets, said clutch member being slidable upon the shaft, an arm carried by said member with which arm the beets come in contact as they reach the upper end of the carrying-belt, whereby the clutch members are engaged and the knife is revolved to sever the top of the beet.

8. In an apparatus for harvesting beets, means for extracting the beets from the ground and conveying them upwardly and rearwardly and presenting the tops in the line of travel, a revoluble shaft, one member of the clutch carried thereby, a sleeve carrying the second member of the clutch and loosely slidable upon the shaft, a knife carried by and revoluble with the sleeve, a stop also carried by the sleeve and forming a point of contact for the beet as it arrives in position to have the top severed whereby the clutch members are engaged and the knife revolved, a cam carried by the movable clutch member, and a fixed arm adapted to engage the cam and retract and disengage the clutch member after a single revolution of itself and the cutter.

9. In a beet-harvesting apparatus, a wheeled frame, plows carried thereby, a lifting-blade, guides and endless traveling belts by which the beets are successively transferred, a transversely and intermittently revoluble cutter by which the tops of the beets are severed when presented, an endless traveling and transversely-movable belt upon which the beets are received after the tops have been severed, and by which they are delivered at one side of the line of travel of the apparatus.

10. In a device for removing the tops from beets, a carrier by which the beets are transmitted, a cutter revoluble transversely to the line of travel of the beets, and means actuated by the movement of the beets whereby the cutter is revolved to sever the top of each beet.

11. In a device for removing the tops from beets, a carrier by which the beets are transmitted successively, a cutter revoluble periodically transversely to the line of travel of the beets, a stop with which the beets come in contact, and mechanism controlled by the stop and actuated by each contact whereby the knife is revolved and a top severed.

12. In a device for removing tops from beets, a traveling carrier for the beets, a cutter revoluble periodically and transversely, a clutch mechanism and a stop against which an approaching beet comes in contact, said stop engaging the clutch and causing a single revolution of the cutter.

13. In a device for removing the tops from beets, a traveling beet-carrier, a cutter revoluble transversely to the line of travel of the beets, a normally disengaged clutch member through which the cutter is actuated, a stop against which the beets come in contact and through which the clutch is engaged to revolve the cutter, and a cam and arm engaged thereby to disengage the clutch and stop the cutter after each revolution.

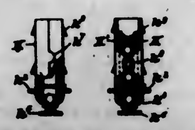
14. In a harvester of the character described, the combination with an unearthing device, of a cutter for severing the tops of the beets, and a beet-arighting device for delivering the beets and presenting their top ends to said cutter, substantially as described.

15. In combination with means for clearing earth from opposite sides of a row of beets, means to uproot the beets, a cutter for severing the tops of the beets, and means to convey the beets thereto, substantially as described.

16. The combination with means for clearing earth from opposite sides of a row of beets, of means to uproot the beets, a cutter for severing the beet-tops, and means for relatively moving the beets and said cutter that said cutter may sever the beet-tops, substantially as specified.

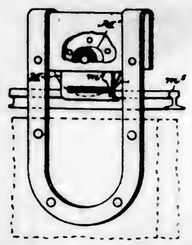
17. In a machine of the class described, the combination of means for separating vegetables from the earth, means located above the surface of the earth for cutting the tops off of the vegetables, and means for delivering said vegetables from said separating means to said cutting means, substantially as specified.

809,695. CASING FOR WHEELS, &c., AND TRACK THEREFOR. HENRY F. KEIL, Brooklyn, N. Y. Filed May 27, 1904. Serial No. 210,142.



Claim.—A sheave-casing K formed in two parts, in the meeting edges of the ends of which parts is formed a step or dovetailed joint k^2, and in the sides of which are formed integral bearings k^3 for a sheave-wheel made by respectively indenting or concaving the central portions of the said two sides, on the side faces of which casing are also formed a plurality of integral extensions, some of the extensions k^3 projecting outwardly, and some of the said extensions projecting laterally to constitute practically horizontal gage-plates or guides k^5, and other of the extensions k^3 being made in depending form, in combination with a sheave-wheel and a track or way.

809,696. CASING FOR WHEELS, &c., AND TRACK THEREFOR. HENRY F. KEIL, Brooklyn, N. Y. Filed May 27, 1904. Serial No. 210,143.



Claim.—1. As a new article of manufacture a sheave-casing having one or more integral depending converging or concave resilient lips or flanges to engage and be snapped upon and partly inclose the head of a track or way, and terminating in outwardly-turned edges.

2. As a new article of manufacture a sheave-casing having depending self-acting, interlocking and clamping means consisting of one or more integral converging or concave resilient lips or flanges to engage and be snapped upon and partly inclose the head of a track or way, and terminating in outwardly-turned edges, and also formed with horizontal gage-plates or guides.

3. As a new article of manufacture a sheave-casing having one or more integral depending converging or concave resilient lips or flanges to engage and be snapped upon and partly inclose the head of a track or way, and terminating in outwardly-turned edges, and also formed with an uneven portion in the face thereof for the purpose set forth.

809,697. TRACK OR WAY. HENRY F. KEIL, Brooklyn, N. Y. Filed July 19, 1904. Serial No. 217,194.

Claim.—1. As a new article of manufacture, a track or way constructed from one piece of sheet metal and comprising in its construction securing-plates, a tubular head, and an intermediate bipartite neck or web located in a different plane from that of the securing-plates, whereby unobstructed undercut paths or passages are formed below the head, both the sides and top of which are constructed and arranged to form bearings for a wheel.

2. As a new article of manufacture a track or way constructed from one piece of sheet metal and comprising in its construction securing-plates, a tubular head, and an angularly-disposed intermediate bipartite neck or web connecting said tube and securing-plate, whereby the latter is disposed at a distance from said securing-plates and in a plane parallel thereto, whereby unobstructed undercut paths or passages are formed below the head, both the sides and top of which are constructed and arranged to form bearings for a wheel.

809,698. DISPLAY-MIRROR. WILLIAM V. D. KELLEY, Newark, N. J., assignor of one-half to Howard S. Jones, Brooklyn, N. Y. Filed Apr. 7, 1905. Serial No. 254,294.

Claim.—1. A display-mirror comprising a glass plate, a transparent silvered coating on one side thereof, a transparent varnish over said silvered coating, and a translucent coating for said varnish, substantially as described.

2. A display-mirror comprising a glass plate, a transparent silvered coating on one side thereof, a transparent varnish over said silvered coating, and a protected light-transmitting coating over said varnish, said protective coating having a surface not easily scratched, substantially as described.

3. A display-mirror comprising a glass plate, a transparent silvered coating on one side thereof, a transparent varnish over said silvered coating, and a protective light-transmitting colored coating over said varnish, substantially as described.

4. A display-mirror comprising a glass plate, a transparent silvered coating on one side thereof, a transparent varnish over said silvered coating, and a coating for said varnish, said coating comprising a pigment paint, adapted to transmit light, substantially as described.

5. The process of forming a display-mirror consisting in thinly silvering a glass plate, applying a transparent varnish thereto, and applying to said varnish a translucent coating, substantially as described.

6. The process of forming a display-mirror consisting in thinly silvering a glass plate, applying a transparent varnish thereto, and applying to said varnish while wet a translucent coating, substantially as described.

7. A display-mirror comprising a glass plate, a transparent silvered coating on one side thereof, a transparent varnish over said silvered coating, and a coating over said varnish whereby reflection from an object behind the mirror is prevented, substantially as described.

8. A display-mirror comprising a glass plate, a silvered coating on one side thereof, a pigment coating over said silvered coating adapted to transmit light, substantially as described.

809,699. CLINOMETER. BERNARD KERR, Jr., Toledo, Ohio. Filed Jan. 19, 1905. Serial No. 241,746.

Claim.—1. In an instrument of the class described, a stock having an opening therein a pair of spaced rings mounted in said opening and having the scales i and i' thereon, a radially-disposed inwardly-projecting arm on each ring, a chair pivotally mounted between said arms and having a pointer at each end thereof adapted to register with said scales, a spirit-glass mounted in said chair, means for turning said chair, and a pin h' and nut h for causing a compression of said arms to lock the chair against movement.

2. In an instrument of the class described, a stock having a transverse opening and a socket intersecting a portion of said opening, a pair of laterally-spaced scale-rings mounted in said opening, arms radiating in parallelism from each side of said rings in position to rest upon the bottom of said bore, connection between the arms of each pair, a plate secured to the stock over said bore and having openings provided in its ends, and a tube secured to and suspended from each opening with its end terminating in juxtaposition to the pair of arms disposed thereunder for the purpose described.

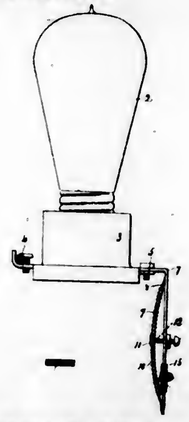
3. In an instrument of the class described, a stock having a horizontal opening therein and vertically-bored portions at the sides of said opening, a frame for supporting a spirit-glass within said opening and having arms projecting from each side thereof longitudinally of said stock and seating on the bottom of said bored portions, and tubes suspended in the bored portions of said stock over the arms at each side of said frame, and a cementitious substance deposited in said tubes and upon said arms for the purpose described.

4. In an instrument of the class described, a stock having an opening therein and borings intersecting a portion of said opening, a scale-ring and spirit-glass mounted in said opening, the said ring having arms radiating from its periphery and disposed in the bored portion of the stock, and a tube suspended in the bored portion of the stock above each radiating arm for the purpose described.

5. In an instrument of the class described, a stock having a transverse opening and borings intersecting substantially half of said opening, a pair of rigidly-spaced rings mounted in said opening and each having arms radiating in parallelism from each side thereof, a plate connecting the lower edges of the parallel arms whereby a trough-like bracket is formed, and a tube suspended within the bored portion of the stock with its lower end terminating in juxtaposition to said plate whereby a cementitious substance may be deposited therein and flow over the plate and between the connected arms.

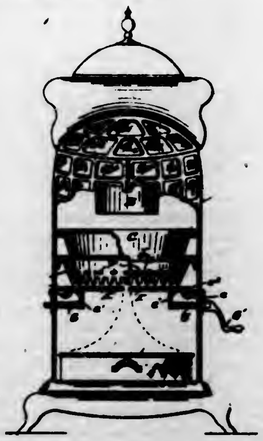
6. In an instrument of the class described, the combination with a stock having sockets formed in the base thereof, of a base-strip or shoe having portions countersunk within said sockets and each provided with an aperture, a screw within each countersunk portion of the base-strip and having its threaded end passed through the aperture therein and threaded within the associated socket, and means for causing an outward movement of the base-strip when a screw is loosened.

809,700. THERMOSTATIC SWITCH FOR INCANDESCENT ELECTRIC LAMPS. JOHN V. A. KERNEY, Jr., New Haven, Conn. Filed Apr. 1, 1905. Serial No. 253,366.



Claim.—The herein-described thermostatic switch for incandescent electric lamps consisting of a bracket connected with an incandescent electric lamp, a bowed plate secured at both ends to one face of said bracket, a contact-screw mounted in said bracket and normally in contact with said bowed plate, electric connection between the bowed plate and one wire of the lighting-circuit and between the bowed plate and the bracket, said bowed plate adapted under heat developed directly by the power of the current of the lighting-circuit to expand and move out of electric contact with the bracket whereby the circuit is broken, substantially as described.

809,701. FIRE-POT AND GRATE. STEFAN KNAPP, Detroit, Mich. Filed Feb. 24, 1905. Serial No. 247,055.



Claim.—1. In combination with a stove or furnace provided with a magazine, a fire-pot, an auxiliary fire-pot, a series of bars

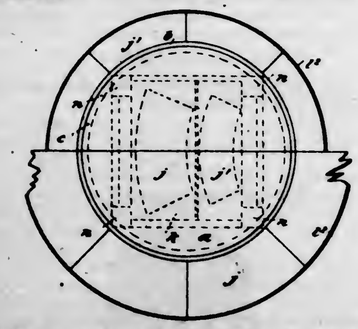
adapted to rest in supports with which the auxiliary fire-pot is provided, said supports being so arranged that the bars, when in position, are below the fire-pot and equidistant from each other, a grate below the auxiliary fire-pot, said grate being in two parts, hinged to opposite sides of the stove-casing, each part being provided with a lug on its under side, and a screw threaded through each side of the stove-casing, below the grate, adapted to bear against the lugs on said grate, substantially as shown and described.

2. In combination with a stove or furnace provided with a magazine, a fire-pot, an auxiliary fire-pot, a series of bars adapted to rest in supports with which the auxiliary fire-pot is provided, said supports being so arranged that the bars, when in position, are below the fire-pot and equidistant from each other, a grate below the auxiliary fire-pot, said grate being in two parts, each of which is provided with a perforated hinge member, a hinge-pin of greater length than the width of said perforated member and upon which said member is mounted to slide and to turn, said hinge-pin being rigidly secured to the stove-casing, each part of the grate being provided with a lug on its under side, and a screw threaded through each side of the stove-casing, below the grate, adapted to bear against the lugs on said grate, substantially as shown and described.

809,702. EYEGLASSES AND SPECTACLES. JOSEPH KOVACS, Newark, N. J. Filed Sept. 19, 1905. Serial No. 279,080.

Claim.—The herein-described means for changing the focal distance of a pair of eyeglasses or spectacles, comprising a supplemental lens provided with a spring-clamp formed from a blank comprising an oblong body portion provided at one end with a projecting member and at the opposite end with a projecting finger, the body portion being provided with a longitudinal spring-tongue which is cut from the central portion thereof, said end member and said tongue being formed into a U-shaped clamp in which the supplemental lens is secured, and said finger being formed into a spring-ring and in connection with said body portion of the blank forming a clamp to engage one of the lenses of the eyeglasses or spectacles, substantially as shown and described.

809,703. TABLE. GEORGE J. KRAEMER, London, England, and EDOUARD ELLER, Geneva, Switzerland. Filed May 17, 1905. Serial No. 260,806.



Claim.—1. An extensible table comprising a top having a downwardly-directed recess adjacent to its edge, extensible supports carried by said top for projection beyond said edge, extension-sections for resting upon said supports, each section having an upwardly-directed flange for engaging said recess, and means for maintaining said flange in said recess and for preventing downward displacement of the edge of the extension carrying said flange.

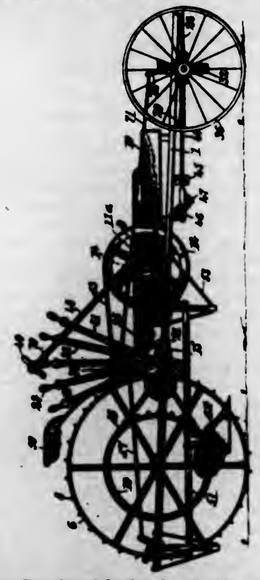
2. An extensible table comprising a top having a downwardly-directed flange and recess adjacent to its edge, a supporting-face below said flange and recess, said flange being interrupted for the insertion of a cooperative locking member into said recess and between the top and such support, and a number of extension members each having a recess for receiving the flange and a flange for entering the recess.

3. In an extensible table, the combination with a circular table-top having a downwardly-projecting flange and a downwardly-opening recess at its under side near its edge, of series of extension members for surrounding said table-top and each having an upwardly-directed flange and an upwardly-opening recess for engagement with the recess and flange of said table-top, a support carried by the table-top for maintaining said engagement, said table-top flange being interrupted by a gap for the passage of the flanges of the several extension members into the recess of the table-top, and extensible supports for the said members.

4. In an extensible table, the combination with a circular table-top, of an annular metallic plate carried by the edge of the table-top and having an annular groove adjacent its lower edge, a series of extension members for surrounding said table-top, a metallic plate upon the under side of each of said members and projecting beyond the inner edge thereof, and having at its upper edge a segmental flange for engagement with said groove, a member fast with the table-top for sustaining such engagement, said table-groove having an opening into it for the passage of the flanges of said extension members, radial grooves in said sustaining member for extensible supports, and extensible supports therein.

5. In an extensible table, the combination with a circular table-top, of an annular metallic plate carried by the edge of the table-top and having an annular groove adjacent its lower edge, a series of extension members for surrounding said table-top, a metallic plate upon the under side of each of said members and projecting beyond the inner edge thereof, and having at its upper edge a segmental flange for engagement with said groove, a member fast with the table-top for sustaining such engagement, said table-groove having an opening into it for the passage of the flanges of said extension members, radial grooves in said sustaining member for extensible supports, and radial recesses for heads on such supports, extension-supports shiftable in said grooves and each having a head for engaging the plate upon the supported extension member.

809,704. MOTOR-PLOW. HENRY J. KYLE, Tipton, Ind. Filed June 9, 1905. Serial No. 264,622.



Claim.—In a plow of the class described, in combination, a frame comprising forwardly-diverging side stringers and having a wheel-space formed in the rear portion thereof, a main driving-wheel rotatably mounted in said frame in said wheel-space, means for driving said wheel, springs attached to the forward extremity of said frame and having laterally-disposed necks attached to said side stringers, an axle attached to the under side of said stringers and wheels mounted upon said axle.

809,705. COMBINED RAILWAY DRAW-HEAD AND AIR COUPLING. LOUIS LEBOUVE, Chicago, Ill. Filed Nov. 21, 1904. Serial No. 233,789.

Claim.—1. In an air or steam pipe coupling device, the combination with a suitably-chambered head, of an aperture in said head, a check-valve for said aperture, a projecting nipple from said chamber, and a check-valve for said nipple, said nipple being adapted to enter the aperture of a corresponding head to unseat the check-valve in said aperture.

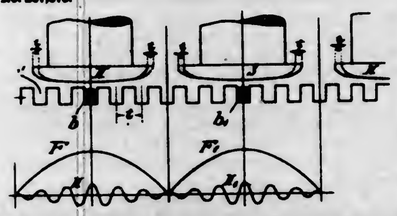
2. The combination with a chambered draw-head or the like, of an aperture leading from said chamber, a pipe or nipple extending from said chamber, slots or the like in the outer end of said nipple, a ball-valve for closing said aperture, a second ball-valve for closing the opening through said nipple, the arrangement being such that when said device is brought into cooperative relation with a corresponding device, one or more of the ball-valves will be opened to admit the passage of a fluid.

3. In a draw-head or the like, provided with chambers connected with the train-pipes, the combination of an aperture leading from said chamber, said aperture being provided with a rubber bushing, a nipple leading from said chamber having slots or openings in its outer end, ball-valves in said chamber adapted to close said aperture and said nipple, a corresponding draw-head provided with suitably-disposed similar apertures and projecting nipples, the arrangement being such that when the draw-heads are connected, the projecting nipples will unseat the balls closing the apertures in the opposite draw-heads.

4. A draw-head having in its bottom a transverse chamber, a pipe connected with the chamber, and a projection extending outwardly from the draw-head and provided with an aperture communicating with said chamber, said projection adapted to extend into an aperture in a corresponding draw-head and communicating with a like chamber therein, and valves adapted to close said apertures when the draw-heads are uncoupled.

5. An automatic car and hose-pipe coupling, comprising similar draw-heads having flat contact-faces and an arm each interlocking with a pin in the other, a lateral recessed hook on said arm, a chamber in the base of each draw-head, a conical tubular nipple extending outwardly from each chamber and adapted for connection in a bushed opening leading to the chamber in the other draw-head, automatic valves for closing said opening and said nipple, and hose-pipe connections on each coupler opening into the chamber therein.

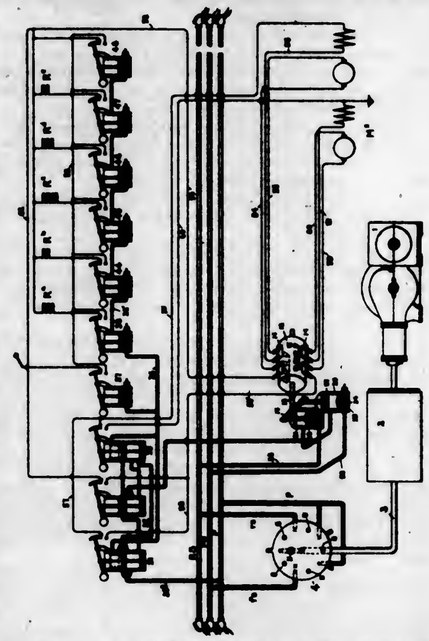
809,706. ELECTRIC ALTERNATING-CURRENT MACHINE. KARL A. LINDSTRÖM, Vesterås, Sweden. Filed June 20, 1905. Serial No. 265,573.



Claim.—1. An alternating-current machine having the armature-winding placed in more or less open slots in the armature-core, and poles of the magnetic field so placed in relation to the two halves of an armature-winding that the waves of tension of higher order, the so-called overtones, induced by certain of the poles in the armature-circuit on account of the discontinuity of the magnetic field caused by the slots of the armature-core, are displaced practically half a period in relation to the corresponding overtones induced by the other poles, substantially as and for the purpose set forth.

2. An alternating-current machine having the armature-winding placed in more or less open slots in the armature-core, and every other distance between the middle lines of the pole-plates of the magnetic field so much greater than the intermediate distances as the distance between the middles of adjacent slots in the armature-core, substantially as and for the purpose set forth.

809,707. PNEUMATIC TRAIN-CONTROL SYSTEM. JOHN B. LIST, Schenectady, N. Y., assignor to General Electric Company, a Corporation of New York. Filed Oct. 16, 1903. Serial No. 177,494.



Claim.—1. A motor-controller of the separately-actuated-contact type, comprising speed-controlling contacts operated by fluid-pressure, and means for automatically regulating the rate at which said contacts close.

2. A motor-controller of the separately-actuated-contact type, comprising resistance-controlling contacts operated by fluid-pressure, and means for automatically retarding the successive operation of said contacts.

3. A motor-controller of the separately-actuated-contact type, comprising resistance-controlling contactors adapted to be operated by fluid-pressure, means for admitting fluid-pressure to the first of said contactors, and means whereby each contactor automatically admits pressure to the next.

4. A motor-controller of the separately-actuated-contact type, comprising resistance-controlling contactors adapted to be operated by fluid-pressure, means for admitting fluid-pressure to the first of said contactors, means whereby each contactor automatically admits pressure to the next, and means for automatically retarding the flow of pressure between said contactors.

5. A motor-controller of the separately-actuated-contact type, comprising resistance-controlling contactors adapted to be operated by fluid-pressure, means for admitting fluid-pressure to the first of said contactors, means whereby each contactor automatically admits pressure to the next, and a time-limiting device for automatically retarding the flow of pressure into said contactors.

6. A motor-controller of the separately-actuated-contact type, comprising resistance-controlling contactors adapted to be operated by fluid-pressure, means for admitting fluid-pressure to the first of said contactors, means whereby each contactor automatically admits pressure to the next, and a pneumatic valve controlling the flow of pressure into each contactor.

7. A motor-controller of the separately-actuated-contact type, comprising resistance-controlling contactors adapted to be operated by fluid-pressure, means for admitting fluid-pressure to the first of said contactors, means whereby each contactor automatically admits pressure to the next, a valve-chest adjacent to each contactor through

which the pressure passes, and a piston in the valve-chest controlling the outlet therefrom.

8. A motor-controller of the separately-actuated-contact type, comprising resistance-controlling contactors adapted to be operated by fluid-pressure, means for admitting fluid-pressure to the first of said contactors, means whereby each contactor automatically admits pressure to the next, means for automatically retarding the flow of pressure into said contactors, and means for permitting an unobstructed flow from said contactors.

9. A motor-controller of the separately-actuated-contact type, comprising a plurality of cylinders, movable abutments in said cylinders, contacts actuated by said abutments, pipes connecting said cylinders, and pneumatic valves in said pipes for controlling the flow of compressed fluid from one cylinder to another.

10. A motor-controller of the separately-actuated-contact type, comprising contact elements each consisting of two cylinders in tandem, a movable abutment in each cylinder attached to a common rod, and a contact-arm connected with said rod.

11. In a fluid-pressure motor-controller, the combination with a contact-arm, of two movable abutments, one for closing it and the other for opening it.

12. In a fluid-pressure motor-controller, the combination with two contact-arms, of two movable abutments for each arm, one for closing it and the other for opening it, each closing abutment receiving fluid-pressure from the working side of the opening abutment for the other arm.

13. In a fluid-pressure motor-controller, the combination with two contact-arms, of two movable abutments for each arm, one for closing it and the other for opening it, pipes connecting the working side of each opening abutment with the working side of the other closing abutment, and a single pipe for conveying the fluid-pressure from each closing abutment to other apparatus, said pipe being closed by the closing abutments when the contact-arms are open.

14. In a fluid-pressure motor-controller, the combination with a reversing-switch, of a series switch, parallel switches, a trolley-switch and resistance-controlling switches, movable abutments for actuating all of said switches by fluid-pressure, and pipe connections for holding the parallel switches open when the series switch closes, and vice versa.

15. In a fluid-pressure motor-controller, the combination with three train-pipes, of a reversing-switch connected with two of said pipes, a series switch, trolley-switch and resistance-switches all in series with said reversing-switch and actuated by a single charge of air from either of said pipes, and parallel switches connected with the third pipe and in series with the trolley-switch and resistance-switches and operated by a single charge of air from said third pipe.

16. In a fluid-pressure motor-controller comprising reversing and resistance controlling and series and parallel controlling switches, the combination with train-pipes connected to the motor-controller, of a valve for admitting fluid-pressure to said pipes in succession to operate the parts of the controller and for exhausting all of said pipes when changing from one pipe to another.

17. In a fluid-pressure motor-controller, the combination of a valve having a turning plug containing two circumferential grooves, one longitudinal groove connecting with one of said circumferential grooves, and several longitudinal grooves connecting with the other, an air-supply pipe leading to the first circumferential groove, an exhaust-port leading to the other, and a plurality of train-pipes adapted to connect with the several longitudinal grooves.

18. In a controller for electric motors, the combination with a plurality of separately-actuated contacts for varying the motor speed, of a pneumatic actuating device for each contact, and pneumatic means for controlling said devices from a distance by compressed fluid under substantially constant pressure.

19. The combination with a plurality of motors, of a plurality of master-controllers connected by pipes in multiple relation, and separate individually and pneumatically actuated contacts regulated by the master-controller for connecting the motors in series and parallel.

20. In a system of train control, the combination with a plurality of cars united to form a train, of motors for propelling the train mounted upon more than one of the cars, separate pneumatically-actuated contacts for connecting the motors in series and in parallel, and a master-controller for pneumatically regulating the operation of said contacts.

21. In a system of train control, the combination with a plurality of electric motor-cars united to form a train, of a plurality of separate pneumatically-actuated contacts on each car for changing the grouping of the motors, a master-controller mounted on each motor-car, and pneumatic connections whereby the master-controllers may operate the motor-controllers.

22. In a system of train control, the combination with a plurality of electric motor-cars united to form a train, of a plurality of separately-actuated contacts for changing the resistance of the motor-circuits, pneumatic mechanism for operating said contacts automatically and successively by compressed fluid at substantially constant pressure, a master-controller on each motor-car, and pneumatic connections between the master-controllers and the said mechanism.

23. In a system of motor control, a plurality of contacts operating in automatic succession, pneumatic actuating means for said contacts, and means controlled by the current in the motor-circuit for automatically regulating the rate at which said contacts close.

24. A motor-controller of the separately-actuated-contact type, comprising speed-controlling contacts operated by fluid-pressure, and means for automatically checking the successive operation of said contacts without affecting the contacts already operated.

25. A motor-controller of the separately-actuated-contact type, comprising successively-operating speed-controlling contacts operated by fluid-pressure, and means controlled by the current in the motor-circuit for checking the progression of said contacts without affecting the contacts already operated.

26. A motor-controller of the separately-actuated-contact type, comprising resistance-controlling contactors adapted to be operated by fluid-pressure, means for admitting compressed fluid to the first of said contactors, means whereby each contactor automatically admits the compressed fluid to the next, and means controlled by current in the motor-circuit for automatically retarding the flow of compressed fluid to said contactors.

27. A motor-controller of the separately-actuated-contact type, comprising successively-operating contactors adapted to be operated by fluid-pressure, means for admitting the compressed fluid to the first of said contactors, means whereby each contactor automatically admits the compressed fluid to the next, a pneumatic valve controlling the flow of compressed fluid to each contactor, and means for operating said valve to check the progression of the contactors.

28. A motor-controller of the separately-actuated-contact type, comprising successively-operating contactors adapted to be operated by fluid-pressure, means for admitting compressed fluid to the first of said contactors, means whereby each contactor automatically admits compressed fluid to the next, a pneumatic valve controlling the flow of compressed fluid to each contactor, and means controlled by the current in the motor-circuit for operating said valve to check the progression of the contactors without affecting those already operated.

29. In a system of motor control, a controller comprising a plurality of separately-actuated contacts, pneumatic actuating means for said contacts, and automatic means for compelling said contacts to be operated in succession.

30. In a system of motor control, a controller comprising a plurality of separately-actuated resistance-controlling, series and parallel contacts, pneumatic actuating means for said contacts, a master-controller and suitable connections for causing the operation of certain of said contacts, and automatic means for causing other of said contacts to be operated in succession.

31. In a system of motor control, a controller comprising a plurality of separately-actuated contacts, pneumatic actuating means for said contacts, a master-controller and suitable connections for causing the operation of certain of said contacts, and automatic means for compelling other of said contacts to be operated in succession.

32. In a system of motor control, a controller comprising a plurality of separately-actuated contacts, pneumatic actuating means for said contacts, automatic means for compelling said contacts to be operated in automatic succession, and means for checking the rate of succession.

33. In a system of motor control, a controller comprising a plurality of separately-actuated contacts, pneumatic actuating means for said contacts, automatic means for causing said contacts to be operated in automatic succession, and automatic means for checking the rate of succession.

34. In a system of motor control, a controller comprising a plurality of separately-actuated contacts, pneumatic actuating means for said contacts, a master-controller and suitable connections for causing the operation of certain of said contacts, automatic means for causing other of said contacts to be operated in automatic succession, and automatic means for checking the automatic succession of the contacts.

35. In a system of motor control, a controller comprising a plurality of separately-actuated contacts, pneumatic actuating means for said contacts, a master-controller and suitable connections for causing the operation of certain of said contacts, automatic means for compelling other of the contacts to be operated in automatic succession, and means for checking the automatic succession of the contacts.

36. In a system of motor control, a pneumatically-actuated motor-controller, a pneumatically-actuated reversing-switch, a source of compressed-fluid supply, means under the control of the operator for regulating the admission of compressed fluid to the actuating means for the reversing-switch, and means controlled by the actuating means for the reversing-switch for regulating the admission of compressed fluid to the controller-operating means.

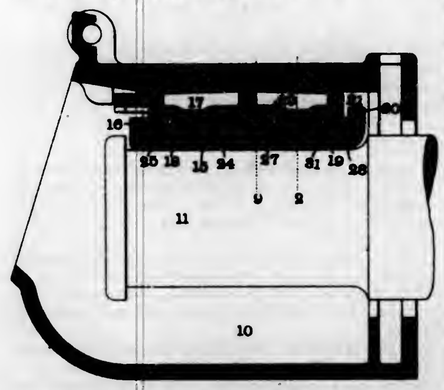
37. In a system of train control, each of a plurality of cars having a reversing-switch, a motor-controller and operating means therefor, two train-pipes operatively related to said operating means, and means for admitting compressed fluid to said pipes for operating the reversing-switches to give forward and reverse motor connections and for operating the several motor-controllers.

38. In combination, a pneumatically-actuated switch, a reversing-switch, and pneumatically-actuated means for actuating said reversing-switch and for controlling the admission of compressed fluid to the actuating means for the pneumatically-actuated switch.

39. A motor-controller comprising a plurality of separate contacts, pneumatic actuating means therefor, and means whereby the operation of certain of said contacts is made dependent upon the operation of certain others of said contacts.

40. A motor-controller comprising a plurality of separate contacts and automatic, pneumatic actuating means therefor, the arrangement of parts being such that the operation of certain of said contacts is dependent upon the operation of certain others of said contacts.

809,708. JOURNAL-BEARING. ARTHUR LIPSCHUTZ, St. Louis, Mo. Filed June 17, 1905. Serial No. 265,727.



Claim.—1. The combination with a journal-box, of a brass having a plurality of depressed flat bearings extending across its upper face, and a wedge interposed between said journal-box and brass and having on its under face projecting bearings coöperating with the depressed bearings on said brass.

2. The combination with a journal-box, of a brass having a depressed flat bearing extending across its upper face, and a wedge interposed between said journal-box and brass and having a projecting bearing coöperating with the depressed bearing on said brass, said projecting bearing being of sufficiently less width than said depressed bearing to permit end play between said bearings.

3. The combination with a journal-box, of a brass, said brass having a plurality of depressed flat bearings extending across its upper face, and a wedge interposed between said journal-box and brass and having projecting bearings coöperating with the depressed bearings of said brass, said projecting bearings being of sufficiently less width than said depressed bearings to permit end play between said bearings.

4. The combination with a journal-box, of a brass having a plurality of depressed flat bearings extending across its upper face, a wedge interposed between said journal-box and brass, and having on its lower face projecting bearings coöperating with the depressed bearings on said brass, and lugs carried by said wedge between the projecting bearings thereon for limiting lateral movement of said brass.

809,709. TRUNK. THOMAS J. LIVERS, Norfolk, Va. Filed Sept. 13, 1905. Serial No. 278,113.

Claim.—1. In a device of the class described, a receptacle having a movable tray, a movable cover for the receptacle, rails on which the tray travels, said rails being pivotally connected at one end with the receptacle, and means for elevating the other ends of the rails upon movement of the cover to open position.

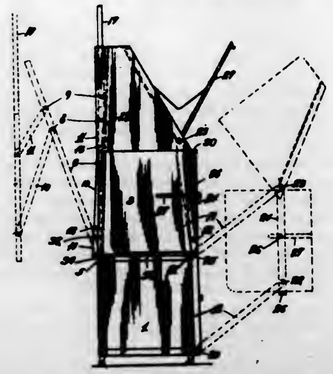
2. In a device of the class described, a receptacle having a movable cover, rails pivoted at one end to the receptacle and having their other ends operatively connected with the cover for vertical movement thereby and a tray arranged for movement on the rails.

3. In a device of the class described, a receptacle having a movable cover, a movable way operatively connected at one end with the receptacle and at its other end with the cover for movement therewith in a vertical plane, and a tray arranged for movement on the way.

4. In a device of the class described, a receptacle, rails pivoted at one end thereof to said receptacle and having their other ends provided with relatively movable sections adapted to form continuations of the rails, links pivoted to said sections and to the cover of said receptacle, whereby movement of the latter to open position will elevate the adjacent ends of the rails, and a tray arranged to travel on the rails.

5. In a device of the class described, a receptacle having a lid or cover, rails pivoted at one end thereof to the receptacle and having their other ends provided with links pivoted to the said lid or cover, thus forming a tray rest and stay for the support of the lid, combined.

809,710. FOLDING BED AND CABINET. NATHAN LUI, New York, N. Y. Filed Aug. 29, 1905. Serial No. 276,212.



Claim.—1. In an article of the character set forth, a base-section, a mattress-frame pivoted thereto, posts, a bureau-plate carried thereby, and brace-bars pivotally connected to said posts and frame and adapted to support the latter.

2. In an article of the character set forth, a base-section, a mattress-frame pivoted thereto, vertical posts, gudgeons formed on said posts, uprights adapted to engage with said gudgeons, a bureau-plate carried by the uprights, brace-bars pivotally connected to said posts and frame and adapted to support the latter, and means for limiting the rearward movement of the frame when it is moved to its upright position.

3. In an article of the character set forth, a base-section, an upper section, a frame carrying the upper section and adapted to maintain it in a horizontal plane, means adapted to allow horizontal play in the frame for said section, and means adapted to swing the frame and upper section over the base-section to the floor.

4. In an article of the character set forth, a base-section, a frame pivotally connected to the said base-section and adapted to swing over it to the floor, an upper section, a support therefor carried by the frame, and guides formed in the sides of the upper section adapted to allow it horizontal play on its support on the frame.

5. In an article of the character set forth, a base-section, a frame pivotally connected to the said base-section and adapted to swing over it to the floor, an upper section, a support therefor carried by the frame, and guides formed in the sides of the upper section adapted to allow it horizontal play on its support on the frame, said frame being adapted to maintain the upper section in a horizontal plane as it swings to and from the floor.

6. In an article of the character set forth, a base-section, a frame pivotally connected to the said base-section and adapted to swing over it to the floor, an upper section, a support therefor carried by the frame, and guides formed in the sides of the upper section adapted to allow it horizontal play on its support on the frame.

7. In an article of the character described, a base-section, an upper section, a frame carrying said upper section, upper and lower extension-bars pivoted to said frame and base-section, and a topmost section formed on a continuation of the upper pair of extension-bars.

8. In an article of the character described, a base-section, an upper section, a frame carrying said upper section, upper and lower extension-bars pivoted to said frame and base-section, and a topmost section formed on an inclined continuation of the upper pair of extension-bars.

9. In an article of the character set forth, a base-section, an upper section, a frame carrying said upper section, upper and lower extension-bars pivoted to said frame and base-section, a topmost section formed on an inclined continuation of the upper pair of extension-bars, and a downwardly-swinging lid hung on the pivot of the upper extension-bars and frame.

10. In an article of the character set forth, a base-section, an upper section, a frame carrying said upper section, upper and lower extension-bars pivoted to said frame and base-section, a topmost section formed on an inclined continuation of the upper pair of extension-bars, a downwardly-swinging lid hung on the pivot of the upper extension-bars and frame, and a stop for said lid.

11. In an article of the character set forth, a base-section, a mattress, supporting-strips for the same hinged to the base-section, and a plurality of hinges formed in the side strips adapted to permit them to be folded back on themselves.

12. In an article of the character set forth, a base-section, an upper section, a frame carrying the upper section, extension-bars pivoted to said frame and base-section adapted to swing the upper section over the base-section to the floor, a mattress supporting-strips for the same hinged to the base-section and provided with a plurality of hinges, and means adapted to secure the strips in their extended position when the upper section has been swung over to the floor.

13. In an article of the character set forth, a base-section, an upper section, a frame carrying said upper section, upper and lower extension-bars pivoted to said frame and base-section, a topmost section formed of an inclined continuation of the upper pair of extension-bars, a mattress, supporting-strips therefor hinged to the base-section and provided with a plurality of hinges, and means adapted to secure the strips to the upper extension-bars and topmost section when in its extended position.

14. In an article of the character set forth, a base-section, an upper section, a frame carrying said upper section, upper and lower extension-bars pivoted to said frame and base-section, a topmost section formed on an inclined continuation of the upper pair of extension-bars, a mattress, a mattress-frame hinged to the base-section and having its side portions provided with a plurality of hinges, pins on the upper pair of extension-bars and the topmost section, and apertures in the mattress-frame adapted to engage with said pins to secure the mattress-frame when in its extended position.

15. In an article of the character set forth, a base-section, upper sections, means adapted to swing the upper sections over and to the same horizontal plane at the base-section, a mattress-frame pivoted to the base-section, posts, means adapted to support the mattress-frame in its extended position and to maintain the posts in a vertical plane when they are moved from the extended to the upright position.

16. In an article of the character set forth, a base-section, an upper section, a frame carrying the upper section, extension-bars pivoted to the frame and base-section adapted to swing the upper section over the base-section to the floor, a mattress-frame pivoted to the base-section, posts, and brace-bars pivotally connected to said posts and frame and adapted to support the latter.

17. In an article of the character set forth, a base-section, an upper section, a frame carrying the upper section and adapted to maintain it in a horizontal plane, means adapted to allow horizontal play in the frame for said section, extension-bars pivoted to the frame and base-section adapted to swing the frame and upper section over the base-section to the floor, a mattress-frame pivoted to the base-section, posts, and brace-bars pivotally connected to said posts and mattress-frame adapted to support the latter.

18. In an article of the character described, a base-section, an upper section, a frame carrying said upper section, upper and lower extension-bars pivoted to said frame and base-section, a topmost section formed on an inclined continuation of the upper pair of extension-bars, a mattress-frame pivoted to the base-section, posts, brace-bars pivotally connected to said posts and mattress-frame and adapted to support the latter, supporting-strips for said mattress hinged to the base-section and provided with a plurality of hinges, and means on the upper pair of extension-bars and topmost section adapted to secure the supporting-strips in their extended position.

809,711. TURBINE. ERNST MAHR, Cannstatt, Germany. Filed Sept. 28, 1903. Serial No. 176,735.

Claim.—1. In a turbine-wheel, curved paddles arranged in concentric circles, the line of curvature of the paddles in one circle intersecting the paddles in the other circle, and the two sets of paddles having fixed relation one to the other, with their concave sides opposed.

2. In a turbine-wheel, curved paddles arranged in concentric circles, the line of curvature of each paddle in one circle intersecting the next preceding paddle in the other circle, and the two sets of paddles having fixed relation one to the other, with their concave sides opposed.

3. In a turbine-wheel, curved paddles arranged in concentric circles, the line of curvature of each paddle in one circle intersecting at an acute angle the next preceding paddle in the other circle, and the two sets of paddles having fixed relation one to the other, with their concave sides opposed.

4. In a turbine-wheel, curved paddles so arranged in concentric circles as to be tangent thereto, the line of curvature of the individual paddles in one circle intersecting at an acute angle the line of curvature of the succeeding paddle in the other circle and the two sets of paddles having fixed relation one to the other.

5. In a turbine-wheel, curved paddles arranged in concentric circles between side plates, the line of curvature of the paddles in one circle intersecting the line of curvature of the paddles in the other circle, and the two sets of paddles having fixed relation one to the other with their concave surfaces opposed.

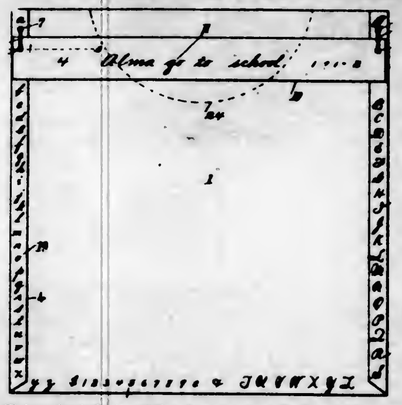
6. In a turbine-wheel, curved paddles arranged in concentric circles, each set of paddles being mounted for rotation in the same direction the line of curvature of the paddles in one circle intersecting the line of curvature of the paddles in the other circle, and the concave surfaces of the paddles in the two circles being opposed.

7. In a turbine-wheel, curved paddles arranged in concentric circles, each set of paddles being mounted for rotation in the same direction the line of curvature of the individual paddles in one circle intersecting the line of curvature of the succeeding paddle in the other circle, and the concave surfaces of the paddles in the two circles being opposed.

8. In a turbine-wheel, curved paddles arranged in concentric circles, each set of paddles being mounted for rotation in the same direction the line of curvature of the individual paddles in one circle intersecting at an acute angle the line of curvature of the succeeding paddle in the other circle, and the concave surfaces of the paddles in the two circles being opposed.

9. In a turbine-wheel, curved paddles so arranged in concentric circles as to be tangent thereto, the line of curvature of the individual paddles in one circle intersecting at an acute angle the line of curvature of the succeeding paddle in the other circle, and the concave surface of the paddles in the two circles being opposed.

809,712. DEVICE FOR TEACHING PENMANSHIP. RALPH W. MATHER, Minneapolis, Minn. Filed May 24, 1905. Serial No. 262,694.

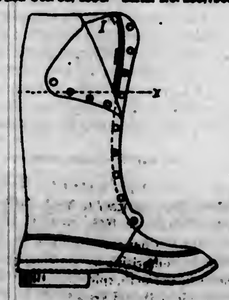


Claim.—1. A device of the character described, comprising an envelop, a writing-base having sets of alined openings therein at the side edges near adjacent corners thereof, a stack of copy-slips having openings therethrough near the ends thereof, and fastening means for said slips inserted through the latter openings and through those of each set in the base, said base forming the back of the envelop.

2. A device of the character described, comprising an envelop having a back constituting a writing-base for a practice-sheet and having the side edges of the front thereof turned over the corresponding edges of said back and secured, the device being formed, near adjacent corners thereof, with sets of alining openings extending through the three thicknesses of material thus provided, a stack of copy-slips having openings therethrough near the ends, and fastening means for said slips extending through the latter openings and through those of each set of said alining openings.

3. A device of the character described, comprising an envelop having a back constituting a writing-base for a practice-sheet and having the side edges of the front thereof turned over the corresponding edges of said back and secured, the device being formed, near adjacent corners thereof, with sets of alining openings extending through the three thicknesses of material thus provided, a stack of copy-slips having openings therethrough near the ends, and fastening-cords for said slips extending through the latter openings and through those of each set of said alining openings.

809,713. WATERPROOF SHOE. PERRY G. MATHEW, Grand Rapids, Mich. Filed Oct. 31, 1904. Serial No. 230,736.



Claim.—1. A shoe, the leg of which is composed of a back, a front and a segmental piece, the back and front being cemented together along their side edges, the back being seamless, and the front having a slit extending downward therefrom, from the upper edge thereof, and the segmental piece fitting into said slit to spread the front.

2. A shoe, the leg of which is composed of a back, a front and a segmental piece, the back and front being cemented together along their side edges, and the front having a depending portion constituting a vamp, and also having a slit extending downward from the upper edge thereof, the said segmental piece being fitted permanently in said slit and serving to spread the front.

3. A shoe, the leg of which is composed of a back, a front and a segmental piece, the back and front being attached together along their side edges, and the front having a depending vamp and a slit extending downward thereinto from its upper edge, the said segmental piece being fitted permanently in the slit and serving to spread the front, and lacing devices connected with the attached portions of the front and back.
